LONDON ENGINEERING DEPARTMENT—II.

Provision of Plant.—The *raison d'etre* of the Engineering Department, so far as the Telephone Service is concerned, is the provision and subsequent maintenance of the plant required to enable any one subscriber to communicate with any other on the system. In order that it may be possible to give would-be subscribers service rapidly, it is necessary to maintain a quantity of spare equipment in the exchanges, and an adequate network of conductors radiating from the various exchanges to all parts of the territory concerned. Plant provision is based on estimates of the probable number of telephones that will be required a number of years ahead, varying from 5 to 20. The development forecast is used, firstly, to determine what exchanges are required and what their capacity from time to time shall be, and secondly, what cables must be laid to the so-called distributing areas and when it will be economical to provide each portion. Additions to line plant in bulk are being made continually, and it will be readily understood how important it is, that the cables shall be provided in the order of urgency in localities in which the telephones will ultimately be required. An enormous amount of money might be wasted if careful calculations were not made in regard to outdoor plant requirements. The money sanctioned for this class of work for the current year is approximately £550,000.

6.—SECTIONAL ENGINEERS (LONDON) AND THEIR SENIOR OFFICERS.

The provision of plant is dealt with in accordance with instructions which are issued to the Sectional Engineers. These are revised from time to time as experience renders necessary. The Sectional Engineer prepares plans for providing or augmenting plant in an area. These plans are forwarded to the Technical Section of the Superintending Engineer's office where they are carefully scrutinised to ensure that the plant to be provided shall be of the required transmission efficiency, and that the methods suggested are economical and in accordance with the approved standards. Schemes for the provision of local line plant are initiated by the Sectional Engineer, for junction plant by the Superintending Engineer, and for trunk plant by the Engineer-in-Chief. These schemes are brought together in the Technical Section and care is taken to see that the requirements of each are provided for when it is necessary to lay down conduits. It is also part of the work of the Technical Section to make financial calculations to determine the number of wires or cables which it is economical to provide at one time, balancing the cost of letting capital lie idle against the cost of doing work in two operations separated by a period of years. Calculations are also made to determine the weight of conductors in order to ensure standard efficiency without undue expenditure on copper conductors.

7.—JOINTING SCHOOL—MAKING CONDUCTOR JOINTS.

In this Section the growth of the telephone system is carefully watched and investigations are made to determine the size, locality and time of provision of new exchanges, the area to be allotted to each exchange and the

Digitized by Google

method of dealing with an area in which an exchange does not exist at present. Requests from the Traffic Branch for additional equipment or facilities are examined and the best methods of providing these facilities at minimum cost are determined. The actual estimates and details of the work are prepared by the Sectional Engineer and subsequently examined by the Technical Section. One important duty of this Section is to co-ordinate the various estimates which are necessary in consequence of the functional division of work and the artificial nature of the Section boundaries in London.

Providing Subscribers' Lines.—Directly an agreement for telephone service has been negotiated by the Commercial Branch a form called an advice note is forwarded to the Engineering Department. This gives the subscriber's name and address and particulars of the service required. An advice note may cover anything from an extra piece of apparatus to a complete installation of many exchange lines and extensions. Many advice notes concern only the internal staff; others concern both the indoor and outdoor staffs. The nature of the work to be done governs the distribution of the advices. Those copies that reach the External Sectional Engineer are first passed to a routing officer, whose duty it is to allocate the spare wires to be utilised so far as they exist. He is enabled to do this by reference to the very complete records which are maintained in each Sectional Office. The case is then passed to an Inspector who arranges for the actual work of making the service connexion. This may involve much or little work, according to the distance of the subscriber's premises from the end of the nearest spare circuit. Frequently it is necessary for the Inspector to make a survey and he may find that a length of cable is required. If no pipe is available it may be necessary to arrange for one to be laid. This involves notice being given to the local authorities responsible for the maintenance of the roads. Again in the event of overhead plant being necessary wayleaves may have to be negotiated. In the latter event the services of a Wayleave Officer are requisitioned. The Inspector having decided exactly how the connexion

8.—JOINTING SCHOOL—WIPING JOINTS.

is to be made issues his instructions to the foreman who is to be entrusted with the work. The foreman's work is completed when he has extended the exchange connexion to a convenient position within the subscriber's premises for the apparatus fitter to connect with the internal wiring. The foreman proves the circuit to the test room at the exchange, and the Test Clerk then advises the Internal side to install the apparatus.

The Fitting Office.—When Advice Notes are received in the Sectional Fitting Offices from which subscribers' apparatus fitting work is managed, they are sorted according to the class of service required. Those with which the external staff are not concerned are ready to be dealt with as soon as a fitter is available. Such cases are the provision of extensions, additional apparatus, internal removals, &c. Those which cannot be proceeded with until the external work has been completed are put aside until advice is received from the Test Clerk that the line is through to the subscriber's premises. The time occupied and material used upon the work is entered upon certain forms, which are collected, associated and checked in the Sectional Engineer's Office. The Advice Notes with date of completion and necessary particulars of the work is then forwarded to the office of the Superintending Engineer where it is examined and returned to the Controller's Office.

Telephone Maintenance.—Telephone Maintenance is divided into two classes, viz., Renewals and Fault Maintenance. The former covers the upkeep and gradual replacement of plant as it deteriorates through wear and tear and natural decay. The replacement of switch sections and the renewal of poles, aerial wires, &c., are examples. The more attention is given to renewals the less will be required on day to day faults. It is of course extremely important that all construction work shall be carried out on sound lines and with great attention to detail. Only in this way can faults on the system be kept low and maintenance costs held within reasonable limits. The Engineer must always be projecting his mind into the future and visualising the condition that will obtain at some distant date. Conditions which may be perfectly satisfactory when a small quantity of plant exists at any point may become very much the reverse as additions are made from time to time.

Faults are brought to light in several ways—*e.g.*, routine tests, which are carried out by the operating staff, and complaints reported by a subscriber. Directly the existence of a fault becomes known it is entered on a docket and is passed as quickly as possible to the Test Room, where it is localised to the exchange, the line, or the subscriber's apparatus. Separate groups of workmen specialise in the clearance of the three clas es of faults, that is to say, the same men who remove faults from the external lines are not expected to enter subscribers' premises and clear defects in the telephone apparatus. The three ideals of the maintenance staff are to have few faults, to clear those rapidly, and to avoid repeat faults. It is generally considered by telephone administrations that the maintenance can be considered satisfactory if the number of faults per line is not greater than one per annum, and this standard has very nearly been reached in London. The Sectional Engineer forwards to the Superintending Engineer weekly returns showing the number of faults that have been dealt with during that period. At the end of every four weeks the results are tabulated on a schedule on which the figures reached at each exchange are shown in detail and in order of merit. These results are posted at the exchanges for the general information of the staff and are scanned with much interest. A healthy rivalry is thus established throughout the exchanges which has a beneficial result, for every effort put forth to reach a high position in the monthly list has its effect in the improvement of the maintenance.

Headquarters Clerical Organisation.—The seventeen branches, each under a Second Class Clerk, into which the Headquarters clerical staff at Denman Street is divided, are supervised by a Principal Clerk, assisted by two First Class Clerks.

9.—APPARATUS WIRING CLASS.

The more interesting features of some of the branches are indicated below :—

WORKS ESTIMATES.—An estimate, as submitted by a Sectional Engineer, contains a statement of labour and stores under the headings of "New," "Shifting" and "Displaced Plant." After this has been checked and approved in the Superintending Engineer's Technical Section, it is passed to the Estimates Section where it is priced and converted into the form required by the Engineer-in-Chief and Comptroller and Accountant General. If the expenditure is approved a Works Order is issued to which all charges in connexion with the work are allocated. Approximately 2,000 estimates for which special Works Orders are required, are prepared during an average year.

In an area so congested as London it is frequently necessary for one set of underground plant to be shifted to provide accommodation for another. When it happens that the Post Office plant is affected in this way some settlement as to who will bear the cost of the alteration is necessary before the work can be put in hand. There is often considerable doubt as to the Powers under which operations are being carried out and not infrequently an extended cross-examination by means of correspondence and interviews is involved before any satisfactory information is forthcoming. Claims under the heading of Repayment also arise through vehicles colliding with fire alarm posts, telegraph posts or Post Office trucks and tents, and a notification that an account will be rendered starts a series of protests and expostulations from the owner of the vehicle, his Insurance Agent and frequently his Solicitor. The evidence is usually only circumstantial, is often unreliable, and where witnesses can be found their statements are not always helpful. During the last twelve months 262 actual Repayment Works Orders have been issued. In many other instances inquiries have been made but without resulting in Repayment Orders.

Digitized by Google

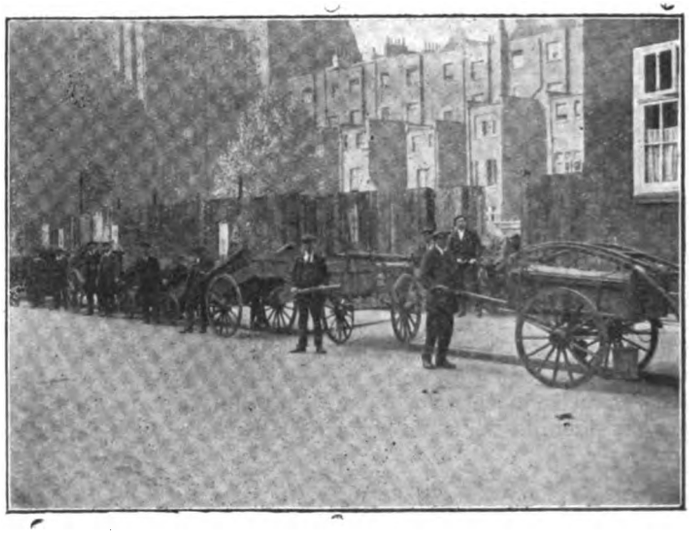
CASH ACCOUNTS.—During the year ended March 31 last the total of Cash Payments reached the figure of £1,071,641, while £83,261 was certified for payment at the Chief Office on account of works carried out in the district. For the current year this amount will be considerably exceeded. The major part of this large sum is expended in weekly payments of wages, and the calculation of the amount due to each individual provides employment for a fairly large staff. Varying rates of pay and war bonus, while presenting their difficulties, afford little trouble to the Cash Account Clerk. The pitfalls lie amongst the smaller items pertaining to extra duty at different rates, substitution, subsistence, lodging, week-end and cycling allowances, travelling time, night rates, pay for accidents on duty, &c. All the information from which the payment due to each workman is calculated is supplied on daily reports and diary slips. These show the particular works upon which the workman is employed. The Cash Account Clerk after working out the correct amount for each man in time for the weekly payment of wages, proceeds to extract and summarise the amounts to be debited to each Works Order or Maintenance Division, and passes these summaries forward for inclusion in the District Monthly Cost Statement. The total of these summaries must of course agree with the total of the pay sheets. Weekly payments are made each Friday to the workmen in the London District, who number over 5,000, the amount due being calculated up to the previous Tuesday evening. Payments are made as a rule at Sectional Engineers' headquarters, but where large groups of men are working at distant points in the section a paying officer pays them on the spot, usually employing a motor car as a means of locomotion.

EXPENDITURE AND STATISTICS.—Apart from the larger works for which detailed estimates are authorised from Headquarters, estimates in bulk are prepared each autumn for the following financial year. These annual estimates cover the works authorised separately and also provide for the sums to be spent during the year upon day to day maintenance, joining up subscribers' circuits, small works, &c. By means of monthly statistics and illustrative graphs a strict watch is kept upon all channels of expenditure. The Management of the District is placed in a position to investigate at

10.—FITTERS ASSEMBLED READY TO RECEIVE THEIR DAY'S WORK.

once any departure from authorised figures. Schedules showing comparative unit costs for the various classes of work in each section are circulated monthly to the Sectional Engineers, who are thus placed in a position to compare their unit costs with similar costs in other sections, and with the efficiency results which the fault returns provide. In this way full value is obtained from the statistics prepared in the district.

STORES.—In order that there may be no delay in connexion with the supply of apparatus and line stores for the extension of the telephone system, 37 separate Section Stocks have been established throughout the district, usually at or near to exchanges, for the purpose of supplying on demand every morning to the workmen on the spot, all stores items for which there is a constant need. These include telephones, switches, flexible wires, cables, insulators, line wire, pole fittings, distribution underground cables, tools, &c. Stores are replenished monthly by the Controller, Stores Department, or direct from manufacturers' works. The average total value of stores and tools held in Section Stocks is £50,000.



In New York the distribution of telephone material is carried out by motor transport from a single central depot. The National Telephone Company made experiments in London in the same direction which were not very successful. At the present time a modified use of motor transport for the delivery of telephone sets is being tried by the Post Office. With all the factors under consideration, however, including the congestion of street traffic, it is believed that delivery from a single central depot can never be justified in London.

In addition to the quantity of stores supplied to Section Stocks very heavy consignments for use upon main Works Orders are delivered directly to the works without passing through Section Stores.

The total value of stores used last year amounted to £531,360, while stores recovered totalled £215,160. Stores vouchers have to be prepared for all stores transactions, whether outwards or inwards, and these vouchers numbering about 200,000 annually, reach the Superintending Engineer's office through regular channels. Each voucher is priced and the amount extracted and summarised to the particular Works Order &c., on which the material has been used. A balance sheet showing the debit and credit values of stores handled is furnished to the Accountant-General monthly.

CONTRACT WORKS.—In addition to the work performed directly by the engineering staff, all heavy works that can be profitably carried out by outside firms under competitive tender are given out to contractors. These embrace the complete equipment of new exchanges and the extension of existing exchanges, the laying of pipes and ducts, the building of manholes, and in some cases the provision, laying, balancing and loading of cables. The expenditure upon such works amounts to about £200,000 per annum. When the accounts are received at the District Headquarters they are subjected to most careful scrutiny in view of the large amounts involved. When all contested points have been settled with the contractors the accounts are certified by the Superintending Engineer and forwarded to the Accountant-General for payment.

TELEPHONES AND PRIVATE WIRES.—In these branches all correspondence dealing with subscribers' exchange lines and private wires, new lines, ceasements and renewals is handled. In most cases two, and in many cases three or more of the District Sections are concerned. The distribution of Advice Notes has therefore to be carefully handled in order that the work at different points may be kept in step. Inquiries addressed to various Post Office officials regarding the probable date of completion of new lines are also dealt with, after consultation with the Technical Section. The applicant is advised when a contract has been accepted that any inquiries regarding its completion should be addressed to the Sectional Engineer,

11.—JOINTERS' GANGS SETTING OUT ON THEIR DAY'S WORK.

whose name and address are given. Inquiries made through other channels, which lead to unnecessary correspondence, are discouraged.

BUILDINGS AND SUPPLIES.—The rapidly expanding volume of work calls for the steady increase of accommodation for the engineering staff, and increased yard and stores space at existing exchanges. Such accommodation is provided on a standard basis. Plans for new and extended exchanges are continually under examination at the present time.

WAYLEAVES.—Before the Post Office can erect poles or lay down underground cables on public or private property wayleaves have to be obtained from the property owners concerned. As regards public property the Postmaster-General holds certain Statutory rights on the subject. There is consequently a considerable amount of correspondence with public bodies and others who have control of the roads, streets, lands or houses over, along, underneath, or across which it is desired to place telephone wires. It is not always easy to ascertain the body or person that has the power to grant a wayleave in a particular case, and it is still more difficult to find one that fully comprehends the powers conferred upon the Postmaster-General by the various Telegraph Acts. Ignorance of the reality of these powers leads to much obstruction at times and needless expense. When the Department fails to come to terms with public or private owners on the subject of a wayleave application, an appeal to the Courts becomes necessary, and much detailed information has then to be prepared for the use of Counsel, including returns, showing the number of vehicles and pedestrians passing along the streets in the course of a day. Photographs of the streets are also put in so that the Court may judge as to the value of the houses and the extent to which a telegraph pole might depreciate their value, if at all.

Digitized by Google

Staff Conferences.—When the London District was reorganised upon a functional basis immediately after the transfer, and a clear and well-defined sub-division of labour was laid down, it was found necessary to ensure strict co-operation between the various sections of the work so that the district as a whole might work as a single unit. To this end staff conferences under the Superintending Engineer are held from time to time at Headquarters, attended by the Assistant Superintending Engineers and Executive Engineers, at which the methods of work and all current problems are fully discussed. In addition the Superintending Engineer confers with the Assistant Superintending Engineers in charge of the main divisions of work, and the Engineer in charge of the Technical Section at fortnightly meetings. All important works are then brought under review, and action is taken where necessary to remove causes of delay and to ensure uniform progress on the part of External and Internal Engineers.

Whitley Committees.—Consistent with the spirit of the times two Whitley Committees are in operation in the London District, one on the Clerical and the other on the Engineering side. The Superintending Engineer is Chairman of both Committees, acting as liaison officer between them. On one Committee he is assisted on the official side by clerical officers, and on the other by engineering officers. The progress made is encouraging. It is felt that the management of the district will be materially helped by obtaining at first hand the views of the staff, while the latter will no doubt benefit by having the official attitude upon points under discussion frankly explained to them at the monthly meetings.

BOLSHEVISTS IN MOSCOW REDUCE SERVICE.

Under the Bolshevist order socialising the telephone system of Moscow the number of instruments has been reduced to 15,000, for "technical reaons." In putting this order into effect the Bolshevist officials cut the number of their own telephones only 25 per cent., while factories and similar establishments must be content with half as many instruments as before. In theory every house is to have a telephone, which is to be located on the stairway, where it is to be accessible to everyone in the house and may be used free. If the neighbours have no telephone in their house they are entitled to make use of the one nearest to their abode. If there remains a surplus of instruments after all the houses are equipped, then doctors, nurses, and the higher Soviet officials may have telephones installed in their own homes.—*Telephony*, Chicago.

THE BAUDOT.—XIII.

By J. J. T.

THE present article may be considered as recapitulative in character, in that it practically repeats Figs. VIII to XI inclusive, which appeared in the November issue of last year. There has been a considerable demand for clearer sketches of the figures above mentioned and it is hoped that the present issue will fulfil that requirement of our appreciative, if critical, readers. The lettering is identical with that of the November 1919 issue (Vol. VI, No. 56) with perhaps one or two slight additions, which in overhauling the diagrams it has been found practical to introduce. For example, the arrow in Fig. VIII*a* denotes the direction of the rotation of the brushes. The segments, too, of each segmented ring have been clearly marked in Roman figures, and the number of each ring has been more distinctly denoted by ordinary numerals. The sectional view of the emerging axle and casing, A^1 of the same figure, has been lettered to correspond with Fig. IX*a*. Fig. X*a* has been drawn out fully, showing all three pairs of brush-*holders* in position. The insulating ebonite collars, now marked J can be more clearly identified, as also the ebonite washers W. It has also been possible

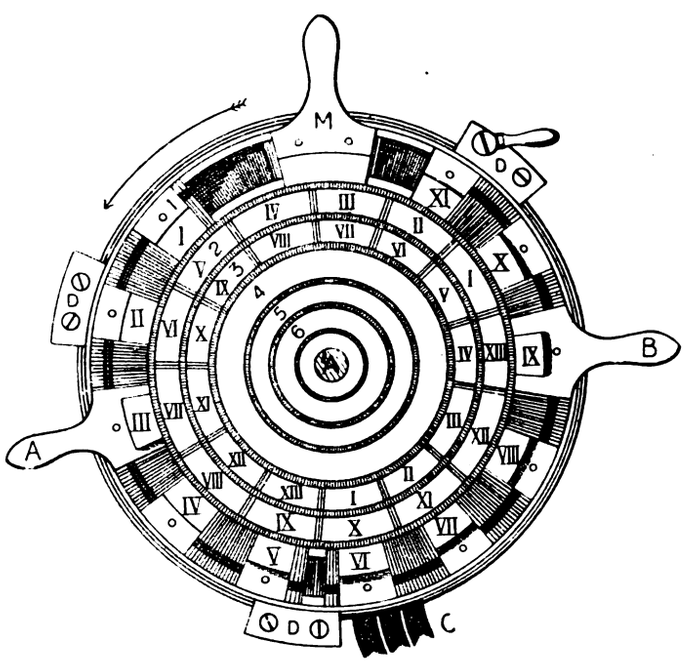


FIG. VIII*a*.

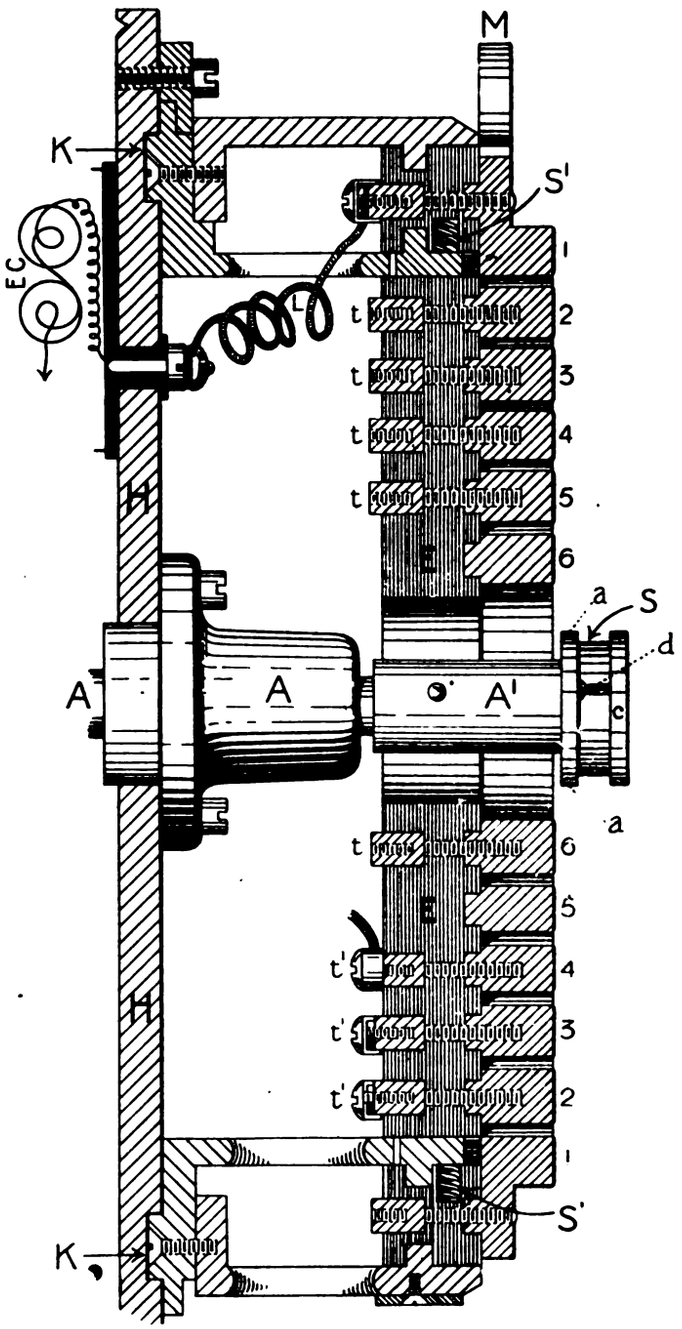

FIG. IX*a*.

Digitized by Google

to show two of the ebonite collars in the newly drawn Fig. XI*a*. The last mentioned figure XI*a* also more distinctly depicts the steel ring S (see also Fig. IX*a*) which by means of the slot *d* carries round the three-armed brush-carrier engaging with the spring-click RR. In addition thereto care has been taken to draw out in clearer detail the twelve-holed collar *a* (see also Fig. IX*a*) together with the pin *b* of S, which pin, it will be recalled, determines the position of S

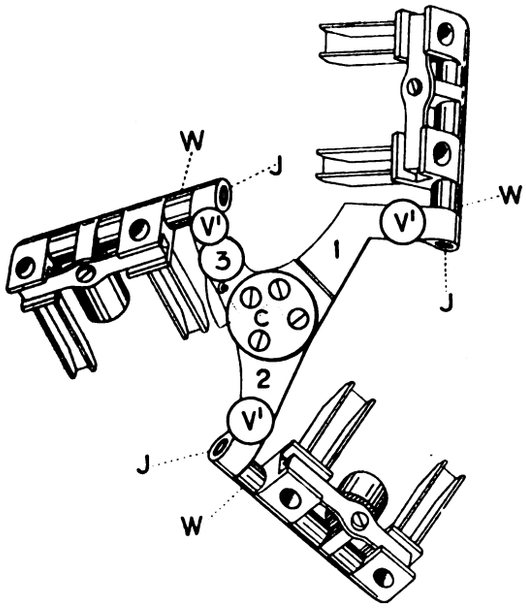

FIG. X*a*.

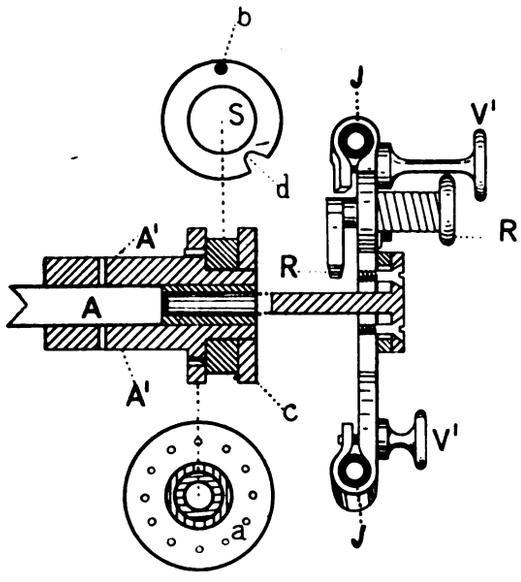

FIG. XI*a*.

as regards *a* and therefore the position of the brush-carrier and its three pairs of brushes relatively to the distributor plate itself.

The steel collar *c* (Figs. IX*a* and XI*a*) it will also be remembered screw S firmly into position against and in relation with the collar *a*.

Forthcoming articles will deal in turn with the Baudot receiver in detail, duplex Baudot, followed by some of the faults, their causes and remedies. This, it is estimated, will practically form a winter series of studies.

(*To be continued.*)

DEPRECIATION.

AT the Master Printers' eighth annual cost conference at Cardiff in June, Mr. W. Howard Hazell gave an interesting paper on the "New Problem of Plant and Machinery in Relation to Costs," which was followed by a keen discussion. The chief question in which telephone and telegraph men are concerned is how provision should be made for the renewal of plant at the end of its useful life. Under present conditions new plant costs from two to three times the cost of the plant displaced; and master printers, like all other business men, consider that the increased cost of renewal should be covered by their tariffs. They argue that their customers should pay, not only for all materials used and services rendered but also, if machines are worn out in their service, such a price as would cover the cost of replacing such machinery. In connexion with the Costing Committee's recommendation that double depreciation should be written off pre-war plant, the second amount being carried to a Special Reserve for the replacement of machinery, Mr. Hazell advocated the keeping of two accounts in their ledgers—one for the value of pre-war plant and the other for the post-war plant on which normal depreciation would suffice. The normal percentage for depreciation in the printing business is 10 per cent. per annum on the decreasing value; and Mr. Hazell did not disguise the fact that, in the case of pre-war plant which was due or nearly due for renewal, the additional 10 per cent. suggested by the Costing Committee would not provide sufficient funds for the extra expense of renewal. He suggested that in such cases it would be wise to consider the desirability of writing off more than double depreciation.

Mr. F. Steel on the other hand was in favour of revaluing the whole plant at present-day prices and charging depreciation at the normal percentage on the ascertained present value. This course, which seems simpler to the lay mind as confining the special calculation to the valuation of the existing plant and avoiding the separation of pre-war from post-war plant, is apparently not without its dangers in the printing trade, chiefly because present-day values are inflated abnormally by the great demand for the limited supplies of new machinery available.

This inflation unfortunately affects all manufactured goods in consequence of the shortness of raw materials as well as of skilled labour for their manufacture; and a considerable measure of common-sense in addition to a thorough knowledge of the business concerned is necessary to ensure that an up-to-date valuation of the plant is based upon a normal post-war period and not upon the current artificial prices created by scarcity of the desired articles. If the valuation on these lines is carefully carried out there is then less chance of over capitalisation of plant with its consequent difficulties in the event of prices falling in years to come as the result of more plentiful supplies of new material, increased production and competition amongst manufacturers.

We are indebted to the *Caxton Magazine* of June for the detailed report of the Conference.

THE TELEPHONE AND TELEGRAPH SOCIETY OF LONDON.

PROGRAMME 1920-21.

THE Meetings will be held at The Hall, River Plate House, Finsbury Circus, and the following papers will be read:—

Date.	Subject.
Oct. 18	"Fifty Years of State Telegraphs." By Mr. A. J. Stubbs.
Nov. 15	"Automatic Telephony in Large Areas." By Mr. M. C. Pink.
Dec. 13	"Studies in Whitleyism." By Mr. F. C. Cook.
Jan. 17	"Scientific Management." By Mr. John Lee.
Feb. 21	"American Telephones and Telegraphs."
Mar. 21	"Imperial Telegraphic Communication." By Mr. A. Avery.
April 18	"Future Wireless Developments.

Digitized by Google

The Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.1. The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. OCTOBER, 1920. NO. 67.

PROBLEMS IN THE FUTURE.

THERE is always a disposition in scientific matters to regard progress as being at an end. It is possibly less evident to-day than it was in the Victorian age, for we have had some fairly salutary lessons. In 1851 the Great Exhibition in Hyde Park represented human achievement and it is not disrespectful to our ancestors to say that to many of them it represented some finality of achievement. To-day we have our own temptations in the same direction. If we take wireless telegraphy we have a good example. It is a wonderful thing to communicate from ship to shore, from continent to continent, without any thing in the way of direct union by wire. But, as a scientist recently said, if so-called wireless had come before line telegraphy, in turn newspapers would have regarded line telegraphy as the tremendous achievement. Moreover, there are many who believe that the later developments will be some fusion of the two, some application of wireless methods and principles to line communication, something of the nature of "wired wireless," of which there is definite prospect to-day. Then there is the application of printing telegraphs to wireless with the advantage of secrecy, a development which is inevitable. To dream in this fashion is not merely a good exercise for the imagination: it is a healthy restraint on our pride. We need not go into the realms of radiotelegraphy and radiotelephony in search of problems. Like the poor, problems are always with us. Oddly, too, they are often elementary problems. How shall we provide for the efficient delivery of telegrams without gross extravagance? It looks easy, but we can imagine the sorrowful despair of an administrator of telegraphs, after strenuous efforts at accelerating the transit of telegrams by a minute or two, watching a dreamy boy standing by the inevitable excavation in the road. What modern science of management can inspire messenger boys—and girls—with the necessity of promptitude in delivery? Then there is the similar question of internal transit. How shall we convey telegrams with reasonably equal rapidity from one portion of a building to the other for onward transmission? No-one will deny that we need some machinery for this purpose, some method of collection and distribution and sortation which will economise human labour. The problems are mentioned by reason of their apparent simplicity, but there are a dozen others which might be mentioned. We need vision to see these problems, and sometimes we want to get away from the trees that we may see the wood.

Then there is the realm of telephony. All is not ended in that fascinating realm. Automatics are picturesque and initially attractive and most of us believe that they will come. That does not mean that all the problems have been settled, in particular the difficult question of the gradual introduction of automatics in a vast town area. There are problems yet ahead of us in respect of charges, especially for small users in small towns, and, indeed, the whole question of service in small towns affords ample scope for ingenious solutions. It is a pleasing prospect to think of everyone carry a telephone in his pocket enabling him to speak to anyone in the world at any moment. That is hardly a problem, but it indicates that just as there is a vista for wireless telegraphy and for international telegraphy, so wireless telephony and international telephony have their vistas. The pocket telephone makes a nice little newspaper paragraph on dull days, but it is quite conceivable that it might have a shattering effect on the world's peace of mind.

Readers of psychology will like to be told of Dr. McDougall's "Group Mind," a study of an aspect of corporate psychology which is receiving much attention at the moment. He ascribes the closer corporateness of mental life to-day largely to the telegraph, and builds up a fine argument in respect of national characteristics on this basis. It is complimentary to our crafts. It brings telegraphy and telephony into a new court of honour. We mention it at this stage because it would seem that future international problems in the way of improving national relationships may have to call in the aid of telegraphy and telephony. So the problems of the future do not merely consist of the development of multiplex printing telegraphs or of automatic telephones or of speeding up messenger boys or of extending the number of call offices; they consist more probably of administrative problems which will realise the value of telegraphy and telephony not merely as carriers of messages between individuals, but as part of the warp and woof of the greater civilisation which, we all hope, is before the world. It is something to bear one's part in such problems, but it is even more so to aim at the efficiency of the service as we give it to-day in order that we may lay a sound foundation for progress.

READERS will be sorry to hear that Mr. Gunston, our popular editor, is seriously ill with pleurisy and pneumonia. They will no doubt miss his familiar touch in the present number and will make allowances for the fact that this number is being edited by unfamiliar hands when the only welcome call is that of the sad sea waves.

Digitized by Google

THE LIGHTER SIDE.

IT is a sad heart that never rejoices and depressing must be the occupation that is not relieved by touches of humour. It is doubtful even whether such an occupation can be found, and the duties in a Superintending Engineer's office do not form exceptions to the rule.

Quite recently one applicant for employment filled up the usual form which bears enquiries as to his age, experience, antecedents, etc., and, thinking these replies were not enough, the man added, "My father has served in the Department 27 years and is at present employed at —— Exchange. I sincerely hope to improve on my father's efforts." Now, you fathers who have sons in the Department, or who wish them to enter, you know what your offspring thinks of your contribution to the advancement of telephony and the good of the State.

Another stated, "Sir, I have found myself very useful in doing anything. Sir, what I have stated is quite correct." No doubt, but it does not follow that other people found him very useful. The jack of all trades is at a discount in these days of specialisation. On one form the following item appeared, "I was two years in the infantry and one in the Signal Service, so I know all about telephones." Alas! how slow some of us must be. We have spent many years in trying to find out all about telephones. In the course of this endeavour we have burnt much midnight oil and spent an undue proportion of our slender incomes on technical books, but the further we got the less we seemed to know, so vast is the field which opens to our gaze. Several years in the Signal Service do not seem to have helped us very much. Perhaps the fault is in us, and this man's statement about the extent of his knowledge humbles us.

A few weeks ago it was necessary for the Department to prefer a claim for damage to a linesman's truck. The boy driver of the vehicle which caused the damage explained to the police constable that "I touched the horse on the behind and it fell down so I jumped off the cart." From other evidence it appeared that the horse, objecting to the treatment administered, bolted and, after upsetting a costermonger's fruit stall, collided with the P.O. truck. The officer who furnished the above details adds "It is not unlikely that the coster's language had something to do with the horse falling down, as well as with the lad's hurried escape from the cart."

A pigeon fancier was recently charged with the cost of erecting game guards to protect his pigeons. The man replied, stating that he hoped the charge would be reduced as "I am only a poor working man with a large family but the pigeons is my hobby." Although rearing a family was not his hobby he appears to have been successful.

Government departments, like railway companies, seem to be regarded as fair game by persons in other respects honest. It is extraordinary, for instance, how a suit bought in pre-war days and now in the last stages of decrepitude jumps in value if it is brought into contact with a freshly painted pole. Claims have also been dealt with recently for damage to false teeth by a falling wire, and another for a pair of boots of which the soles had been torn off by a vicious joint box cover.

The anonymous letter writer invades even the sanctity of the engineers' office. Here is a sample of which we make a present to the reader, hoping that he will be able to unravel the mystery. "Sir they run up and down your telephone pole on the roof of XX High Street and the boy scouts take them messages I have watched. You will greatly oblige and the betting men live round the corner and talk on the wires."

The effort to impart technical knowledge to budding Kelvins and Edisons is not unrelieved by a lighter touch.

One lecturer was explaining the operation of a Wheatstone Bridge to a class of young workmen, and asked them what they knew about a "ratio." One replied, "The bloke what writes *John Bull*."

A colleague in the Traffic Branch relates the following incident; and as traffic officials never depart by a hair's breadth from strict veracity it is given without reservation. A subscriber who had been told repeatedly that the wanted number was "Engaged," replied, "Go to H—— I never wish to hear your voice again." The telephonist, remembering her instructions to oblige subscribers where possible, sweetly replied, "If you really do not wish to hear my voice again had I not better go to the other place."

Now that workmen are brought within the scope of the Income Tax returns the usual forms have been circulated. One was returned with the following remark, "Sir, I belongs to the Foresters and don't wish to join the Income Tax."

One subscriber insisted that the chief engineer should be sent to see his telephone and in support of his claim stated, "I am a scientist myself and do not wish to discuss my trouble with a non-technical man," An engineer made a visit and the subscriber stated that he received terrible shocks from his telephone. As the engineer could find no fault, he asked the subscriber to make a test call. He did so, and when asked if he experienced any shock said, "No, I don't feel it at the time but about ten minutes afterwards."

As was stated at the beginning, it is a sad heart that never rejoices, and incidents which would otherwise irritate a busy man may be made to minister to the joy of life if viewed in the right spirit.

J. G. H.

TELEGRAPH DELAY AND SUMMER PRESSURE.

BEFORE this problem can have been properly discussed, the "season" will be over once more, and whatever lessons it may have for traffic administrators, it can be definitely asserted even now (August) that though the year 1920 may have presented "the first opportunity for six years of providing an efficient and speedier service," that opportunity has been lost; and the situation generally during the season that has already approached its zenith has been even worse than in the years immediately preceding 1914. Having failed, however, to take advantage of the flood there is no reason why the ebb-tide should not be utilised to formulate a true policy that shall, in 1921, do something, however small, to restore the British Telegraph Service to the enviable position of Preece's eulogy.

The development of machine telegraphy as Baudot circuits are multiplied between the larger provincial towns is one direction in which reform can be anticipated, but it is little use accelerating the transmission of telegrams *between* large centres if they are to be subsequently delayed there, and though transmission over trunk circuits (by which I mean fully loaded circuits to and from the largest offices) is one of the most important aspects of the case, it by no means exhausts the subject. I am inclined to the view that in bestowing close attention to circuit delay superintendents are apt to overlook the effect of sluggish circulation. Readers of Mr. Stewart White's lumber stories will find some analogy in the incidents of block and release that are (or were) the accompaniment of water carriage along the great river systems that thread the forest regions of the North American continent.

Both main and subsidiary circulation tables should be carefully staffed, and specialisation in this non-manipulative occupation should be encouraged by systematic training during the non-season period of those officers who show aptitude. I would suggest that at the main circulation the traffic should be dealt with by progressive selection. It should fall into a common receptacle provided with divisions conveniently arranged. The first circulator need not be the most expert. He or she will deal with telegrams whose circulation can be instantly determined. There must be no hesitation, no reference to records, no consultation of lists, or even memory. If the mental response is not immediate to the stimulus provided by the sight of the name, if the strain of action—observation, selection, disposal, is not started automatically, the

Digitized by Google

form should be passed forward to the nearest neighbour who will repeat the process. If the grading is carefully done, by the time the third circulator is reached the number of the telegrams for whose circulation it is necessary to consult lists will be reduced to a minimum. Efficiency will be attained by interchange of positions; and knowledge and experience come with practice. Transit to secondary centres, whether by hand or automatic carriers, occasions the maintenance of force which, for a more restricted area, repeats the processes of the main circulation. It is difficult to see how this can be avoided and the marking of individual forms is an assistance: but no doubt something could be done to expedite the work if the batches for the respective circuits could be kept separate once they have passed the main circulation centre. If this could be accomplished by a single simple fold it would probably be found that nearly every batch contained at least one "key" message which would reveal the intended circuit. But the main point is that there must be individual specialisation and fortunately it is not infrequently found that manipulative expertness and aptitude for circulation duties are not combined in the same person. A "square peg" system therefore, leads directly to imperfect functioning and consequent inefficiency.

There is another minor point that needs attention. It was at one time insisted that a good start at ten o'clock would be effectual in preventing the "cushion" of accumulated traffic that acts as an absorbant buffer against the efforts of staff and supervision at the present time. The deferment of the general opening hour until 9 a.m. has undoubtedly led to the intensification of business in the first hour of the morning and the compression of commercial activities has changed the incidence of the pressure. It is now more than ever necessary to ensure that channels shall be promptly opened, and to this end it may be desirable to create a reserve of staff by bringing forward some attendances from 10 to 9.45 a.m. This is more especially the case in dealing with specialised traffic, *e.g.*, that pertaining to the trade in perishable foodstuffs, fish and fruit. The importance of accelerating telegraphic communication between important centres concerned in the distribution of supplies—Aberdeen, Grimsby, Hull, Milford-Haven and, in a more local sense, Fleetwood as regards fish, and the agricultural ganglia for fruit and vegetables—and the *entrepôts* cannot be exaggerated. It is disadvantageous to all parties. The vendor, obtaining his forecasts quickly from his agents in London, Birmingham, Glasgow, Liverpool, Manchester, is able to decide which affords the best opportunity for the disposal of his goods, which may then be promptly despatched, and this promptitude will be reflected by a speeding up in their delivery with increased sales, better condition of the merchandise on reaching the market, an improvement in the circulation of the supplies all round. If it paid the Department to occupy long lengths of line to afford simultaneous communication from a race meeting whose traffic is purely of secondary or even tertiary importance to the community (the press excepted) to half a dozen first class offices, the system should rise to the occasion in the discharge of its functions in all that concerns the well being of the population as a whole. If it is to be true to its ideal it will make service its first claim and ignore the question of relative seen profits.

Even when trunk communication has been brought to a high pitch of efficiency the problem has not been wholly solved. Local traffic must be catered for and both long distance and local traffic are dependent for complete success upon delivery arrangements. The final disposal of telegrams after receipt, collection, circulation to main or subsidiary delivery offices, preparation for envelope, or transfer to telephone room all impose checks before the addressee is reached and in some instances the effect may be not unfairly compared to varicose veins in the body physical. The remedy in each case is similar.

It is by no means certain that delivery from numerous branch and town sub-offices represents the best arrangement. The weakest link in the whole chain is the messenger and he (or she) is of necessity subject to the most imperfect supervision, for inspectors cannot be omnipresent. I suggest, therefore, that two messengers at two adjacent offices are likely to give a more imperfect service than four concentration at a single office whose site has been carefully chosen. If bicylces can be properly housed and the locality is one through which heavy, or rapidly moving traffic is not constantly passing, it will be found that the additional distance traversed is more than compensated by the greater speed achieved. Comparison between cycle and foot locomotion is so greatly favourable to the former that the point does not need to be laboured. Local traffic is indeed a most important part of telegraph business. The transmissions and handlings may be as few between London and Belfast as between Brighton and Hove: yet it is difficult to satisfy a complainant who produces evidence that the time occupied in each instance is the same. And it would be more difficult in many other cases where a well organised and frequent tram car service enables the sender to "beat the wire." Here it is not inopportune to refer to the competition between the express letter and the telegram as local traffic. Frequently it is possible to communicate more quickly by the express service, and the development of the telephone express letter, which has not proceeded to any great extent will increase the severity of the competition.

A word must be said regarding increased circuit accommodation. To substitute duplex for simplex, quadruplex for duplex, generally involves engineering work at least at one office, though a spare set may be available at the other; and a cheaper means of providing spasmodic additional channels should engage attention. Has our Army signal experience taught us nothing? Or are we to assume that there are insuperable obstacles to superposition and the employment of vibrators or other kindred instruments as auxiliary circuits? Possibly there are external influences which prevent their use, but short of unfavourable experiment the suggestion should not be ignored. Such circuits could be more easily brought into use and could be accommodated in the instrument room, so avoiding further circulation to telephone room with its attendant further congestion of a sister service that is sorely pressed to meet its legitimate requirements.

The average system has imposed a heavy task upon supervisor, and administrators and what was a good servant in the solving of theoretical problems has been converted into a bad master. It has definitely depreciated the service, and is the parent of public complaint. In fact, it is open to doubt whether it has not thrown so much work on writing duties as to have failed as a true economy. It has deadened, if it has not entirely destroyed, that pride of craft which at one time produced the increased energy to meet the emergency. The "flyers'" days are finished and his achievements to-day occasion not astonishment at his skill and resource, but surprise that he should have been willing to spend himself in an effort that is regarded as the spinning of a caged squirrel. Many suggestions for dealing with seasonal pressure will lead to improvement; but the true path towards the establishment of full efficiency lies in the re-creation of *esprit de corps*. That is neither an easy nor rapid course. Already there are in the field proposals towards its resuscitation, but as yet not a ray of light illumines the sky of that dawn.

EDGAR C. GATES.

TELEGRAPHIC MEMORABILIA.

As this is the commencement of yet another new volume it would appear to be an opportune moment for thanking the many friends for their assistance during the past twelve months, sometimes in the form of real helpful criticism, sometimes by useful and opportune copy, sometimes in the shape of unstinted praise of the conduct of our JOURNAL and sometimes in somewhat unmerited laudation of this particular column. Never once has the writer met with the note of acerbity. It is just this latter feature which is perhaps the most helpful in a task which at times draws appreciably upon one's time and energy. To all readers then, at home and abroad, the sincerest thanks.

Three months have passed and the Urgent Rate for Foreign Telegrams has become part and parcel of the City man's economy, although the latter is by no means alone in realising the present convenience of the system. It is hoped by this time some of the virulent critics of early July may have repented them of such dicta as "In our opinion it is simply a blunder; one of the familiar incompetencies of the Post Office," "an endeavour to turn its own (the Post Office) *in*efficiency into profit," "an indirect subsidy to

Digitized by Google

aeroplane postal service," "a backhanded method of raising the general rate," or the final sarcastic thrust of, "a brilliant effort to overcome congestion of traffic." With one more quotation the subject may well be closed. It is the general comment of another section of the press upon, "hasty press criticisms" and reads: "such silliness is an example of how silly a certain section of the press can be." Thus deep calls unto deep!

The heartiest congratulations are tendered to Mr. H. Pirie, of the Lowestoft Repeater Office, late of the Cable Room, London, upon receiving the much-coveted honour of the Silver Medal for the best Telegraphy (Honours Grade) paper in the United Kingdom. By a happy coincidence the previous post delivered the Mons Star to our much respected colleague.

Yet another Anglo-Continental restoration. On Aug. 20 we were delighted to obtain telegraphic touch with our colleagues at the greatly suffering town of Lille, and tender them our heartiest congratulations upon the event. We were, however, sorry that at the same time this necessitated the disappearance from our list of direct communications with the historic port of Dunkerque. This latter line has proved of inestimable value from 1914 up to the above-mentioned date and we were really sorry to say *au revoir* to our very helpful friends at the latter office. Paris Bourse 2nd Simplex Baudot Quad has also been re-opened and a new Baudot Simplex established between London and Bordeaux.

The opening of the split Baudot duplex between Liverpool, London and Havre seems to be a deferred hope not to be realised within the service lifetime of many of us. Although the apparatus is ready and actually working on the Liverpool-London section, it is understood that no accommodation can be hoped for in the Central Telegraph department of the great French port, until—a new office is built in that city! A similar arrangement between Manchester, Leeds and Newcastle-on-Tyne was inaugurated on Aug. 16: thus the premier place in this type of Baudot is taken by our Inland department.

It is also interesting and encouraging to place on record the re-establishment of Hughes duplex between London and Bremen which event occurred on Sept. 7, as also an increase of traffic channels between London and Leipzig on the 20th ultimo by means of the same type of duplex. Emden Hughes duplex was re-started on the 13th. The latter apparatus refuses to be blotted out of the telegraph world, and given carefully trained operators of the "touch-typing" standard of efficiency and experienced mechanics who know how to overcome the whims of a Hughes when heavily worked on lines subject to retarded signals, there is still a place in the sun for the old professor's scientifically planned instrument.

It is equally pleasant to record the opening of a Baudot Double duplex circuit on Aug. 24 of this year of turmoil between London and Frankfurt A/M. This increase of traffic channels formed part of the scheme for the extension of Baudot working between this country and Germany, the execution of which was suspended six years ago. It is one of the hopeful signs amidst all the chaos of these *post*-war years that the spirit of renewed international confidence is gradually permeating society. Telegraphy has had its hard duties to perform during hostilities, and it may surely be written of our craft both here and elsewhere that it is with new zest that all sane men and women once more witness its application to the more wholesome task of the welfare of the nations.

The Baudot Triple duplex trials between London and Berlin up to the moment of despatching this copy to the printers had not given satisfactory results Even prior to the war this high ideal of six-channel exploitation of every Anglo-German submarine cable conductor had been viewed by certain traffic officers in both countries as the knife-edge limit. Conditions to-day are certainly less favourable, as is to be expected.

The Cable Room, London, will surely have to change its code of T.S.F.! Not long ago two highly placed Continental telegraph officials visiting the C.T.O., upon entering the Foreign Telegraph Section at headquarters and viewing the blue lettered legend of "T.S.F.," immediately exclaimed: "*Ah, voila la salle de Télégraphie Sans Fils!*" The visitors were courteously informed that our wireless department had by no means assumed such extensive dimensions, that we were certainly living in expectation of developments, but that for the present our international traffic was still being dealt with by submarine cable.

The report of the Great Northern Telegraph Company is to hand and the Directors in announcing a dividend of 22 per cent. for the financial year, after relating the history of their interrupted cables in certain of the mine zones sound the pessimistic note regarding the present year. This they anticipate is not likely to prove so successful an one as that to which the report refers. They have, however, been able to put substantial sums both to the Reserve and Renewal funds.

A contemporary, much interested in electrical illumination and electrical signalling on railways, brings the rather interesting historic fact to light that the pioneer of furnishing light for carriages was Thomas Dixon, guard of the "Experiment," a coach on the Stockton Railway in 1825, who provided penny candles *at his own expense* for the benefit of his passengers.

The present moment is seized to thank the Zurich office for specially courteous aid during the month of August, when westward communications were in a more than usually tangled after-war condition. The breakdown of the underground section in the north of England for a comparatively brief period in August last naturally caused considerable inconvenience, and only proved the obvious, that, on the earth, above the earth, or under the earth, Nature will occasionally laugh at Man's works do what the latter will. This is, however, in no sense an adverse criticism of the universally acknowledged advantages of our air-spaced subterranean system.

With our Inland system of telegraphy there is undoubtedly much to be said for the principle of equalisation of delay, but it is a matter of very serious debate whether this principle should be inflexibly applied to Anglo-Continental traffic. London's communication with a country which we will call A is working well, that to a country beyond which we will term B, and passes through A is very defective. Let us say there is a matter of x hours to B but only $x-y$ hours to A. "Equalise delay" says the order and on the surface the principle of equal treatment of all telegraphic traffic appears as self-recommended. But A himself is suffering from a block of traffic to B by all outlets so that if London holds back the traffic of A in order to place that of B in chronological sequence and to divert the latter to A, the traffic of A is uselessly delayed for the very simple reason that B's traffic has been preferentially signalled to A only to await transmission in the traffic boxes of the latter. It has repeatedly happened that a foreign station A situated in the circumstances recited above, has eventually been compelled to despatch by post the very traffic which has held back the transmission of its own particular telegrams. Not yet have continental telegraph centres accepted the principle of complete mutual help which may in any way tend to act detrimentally to their own particular traffic. This view-point is by no means so fully recognised on this side of the English Channel as the occasion would appear to demand.

One cannot, for example, get our Continental colleagues to readily agree that their own particular traffic should be held back in order to permit of the transmission of *diverted* traffic of another country beyond them. They appear to reason upon the grounds that, "here are excellent lines in excellent working condition specially erected for dealing with traffic vitally connected with the commerce of our own country. Beyond us and beyond our maintenance limit are other lines not so well maintained and generally working badly, due to electrical, political or economic causes with which we have no concern, and for which we are not responsible." We are willing to help but our own traffic comes first. The position is not an illogical one. The idea that European "ways and communications" should be planned and worked for the common good of all European nations has not yet laid hold of the European mind which very extensively moves along narrower grooves, and within at times very strict geographical and ethnographical limitations.

We dwellers in the British Isles are too apt to forget or at least to underestimate our own naturally detached view of these matters and at the same time are prone to become altogether too insular and therefore perhaps unduly impatient with those of our colleagues abroad, whose view of these matters is rather that of the obverse of the medal.

Owing to ill-health, Mr. J. Howgego, overseer of the Cable Room, who took service with the late Submarine Telegraph Company some few years prior to the transfer of that Company's cables to the State, has been compulsorily retired. It had been noted for some time past that his old vigour was lacking and the best wishes of many friends follow him into what is hoped will prove at least the less stressful period of retirement. Mr. C. S. Ireland—to whom our congratulations—fills the vacancy thus created.

It is with the keenest sense of loss that one records the passing away on the 6th ult. of Mr. Archie Robinson (also formerly of the Submarine Telegraph Company), late Overseer of the Cable Room. A more earnest and painstaking officer in every duty confided to him or any task he undertook one could scarcely hope to find. Those who knew him most intimately are united in their high appreciation of his geniality, his kindliness and his wholehearted unselfishness, traits that were never more evident than in the closing weeks of a comparatively brief illness. To his bereaved wife and children the staff respectfully offer their tenderest expression of sincerest sympathy. He was laid to rest in Lewisham Cemetery on Sept. 9, a number of representatives from the office being present to pay due homage.

From a paper by Mr. Philip R. Coursey, published in the *Wireless World* for June, on *Atmospheric Elimination in Wireless Reception*, it is evident that many active brains are working upon this perplexing problem. It is regrettable that certain members of the lay press appear to make no real attempt to study the very real difficulties of wireless telegraphy before attempting to enlighten the general public upon the future of telegraphy and telephony without wires. One meets numerous friends and acquaintances otherwise well-informed who are unfeignedly surprised that the Government has not long ago superseded submarine cables by the "more modern methods of Marconi." (*sic*).

That these and other difficulties will ultimately be overcome one may scarcely doubt seeing the really marvellous strides that have been made in the study of this method of communication. When, however, one of the highest authorities on this subject states that "Wireless is still in the melting-pot," prudence should surely demand a patient silent waiting.

The technical student will appreciate the following as somewhat typical of the difficulties and fineness of adjustment necessary to obtain the best results for emitted signals when Morse Signalling on High Frequency Circuits. It is known that with this system the speed of the high-frequency generator should be constant. The delicacy of this necessary constancy is realised when one reads: —"A speed variation of $+\frac{1}{4}$ per cent. is already sufficient greatly to reduce the strength of the emitted signals and a limitation of the speed variation to $+\frac{1}{10}$ per cent. is desirable." These few interesting words are excerpted from an article by Herr Dornig in the *Elektrotechnische Zeitschrift* of May last.

Digitized by Google

THE SECRETARY'S OFFICE (INVESTIGATION BRANCH) *versus* THE CENTRAL TELEGRAPH OFFICE.

I must confess to an abject ignorance of the rules of the game of golf, and to only a passing acquaintance even with its language. As regards the latter I have been informed by some junior members that it rhymes with "cough" which does not surprise one, seeing that the latter is unable to rhyme with "tough" according to rules laid down by some unknown Anglo-Saxon academy and must therefore quite naturally find its vocal affinity like other affinities in strange and unlooked for places. I have watched and listened carefully and have tried to associate other words with certain parts of the game; for example, when an ardent player after careful poising and timing his steel-shod weapon succeeds in driving the little white ball about two inches along the grounds and a few clods of earth about six feet in the air! A *mis-cue* of this description is sometimes followed by what a lawyer recently described as "a vocal sigh," at other times by words somewhat after the Shavian order. Despite the writer's ignorance, however, it is with some confidence that the following results are appended of the competition which took place on the Wanstead Park Links on Sept. 1. Upon the result from a golfian point of view one need not dwell. That is self-evident, but the happy association of the Secretariat with representatives from the C.T.O. in the search after healthy recreation must necessarily result in a more healthy psychological atmosphere in which the daily duties of both sections are performed. We should be pleased to record a similar competition between the C.T.O. and the Engineer-in-Chief's department.

SINGLES.

C.T.O. *Secretary's Office.*

Mr. D. K. Hain beat Mr. J. H. Shinner 5 up and 4 to play.
Mr. R. Hain halved with Mr. C. W. Whitehurst.
Mr. A. W. Edwards beat Mr. J. P. Leckenby 4 up and 3 to play.
Mr. E. Woods beat Mr. A. H. Bishop 3 up and 2 to play.
Mr. A. F. Reeves beat Mr. F. J. Young 5 up and 4 to play.

FOURSOMES.

Messrs. D. K. and R. Hain beat Messrs. Whitehurst and Leckenby 3 up and 2 to play
Messrs. Reeves and Woods beat Messrs. Bishop and Young 3 up and 2 to play.

ADDITIONAL SINGLE.

Mr. A. W. Edwards beat Mr. J. H. Shinner 5 up and 4 to play.

J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

ACT OF GALLANTRY.

It is with very great pleasure that we record the following facts:—

On August 24, while work in connexion with the Engineering Department was being carried out on the River Lea towing path, loud calls for help to rescue a drowning boy were heard. Mr. J. W. D. Billson (Acting Inspector, North External Section), who was present, at once plunged into the water and succeeded in saving the boy. The heroic deed was accomplished at great risk to his own life, as Mr. Billson in his efforts became entangled in the weeds, and had to contend with about six feet of mud at the point where the boy was sinking. We understand that the circumstances have been reported to the Royal Humane Society with a view to some suitable recognition of the bravery being made.

* * *

Thanks to the kindness and courtesy of the Submarine Superintendent, Mr. Bordeaux, the London Committee of the Institution of Post Office Electrical Engineers were able to arrange a very interesting outing on Wednesday, September 8, when a visit was paid to the cable ship *Monarch*. Between 20 and 30 members of the Institution, including Lt.-Col. Booth and Mr. Tandy (Superintending Engineer, South Eastern District), journeyed by train from London Bridge to Charlton and thence by tram to the Submarine Depot at Woolwich. Here Mr. Bordeaux showed the visitors some of the mysteries of the Depot and briefly told the story of some of the exploits of the Submarine Department during the war. A fine collection of submarine cables from the earliest laid to the most recent types is held in the Superintendent's office and one would have liked to have spent more time than was available in inspecting these, as it was evident from the little we heard that the history of these cables was intensely interesting.

By means of boats the party then went out to the cable ship itself which was lying off the Depot wharf. Conducted by the various officers who acted as guides, the ship was explored from end to end. As our readers are probably aware H.M.T.S. *Monarch* is an entirely new vessel, having been built in 1916 to replace the old *Monarch* which was sunk by a mine during the late war, and lies, so we are told, at the bottom of the English Channel about five miles from Folkestone. The present ship, therefore, is quite up to date, and has the very latest gear both for navigating purposes, and for dealing with the testing, repair, and replacing of submarine cables. We were greatly impressed by the fine machinery installed for the purpose of taking cable on board, and for paying it out at sea. The engines for these operations were built by Tangyes, Birmingham, and we were assured that no cable ship had a finer set. A cable for the repair of one of the German cables was being taken on board while we were there, so that we had an opportunity of seeing the machinery at work. Equally interesting were the chart room, range finder, the wireless room and the arrangements for testing, the details of all of which were carefully explained by our guides, to whose patience and consideration we owe, to a large extent, the success of the visit. Tea provided by the officers in the ship's saloon brought a very enjoyable afternoon to a close. The necessity of returning ashore in small groups gave us no chance of expressing our gratitude to our hosts, and we should like to take this opportunity of saying how much the hospitality of Mr. Bordeaux and his staff were appreciated by all who had the good fortune to be present.

* * *

Major Kennedy, late Assistant Superintending Engineer of the London Engineering District and now of the Air Ministry, was seen in town recently looking rather worried. We wondered whether this was due to the fact that he has left the life of ease in this Department, or because he was negotiating the London traffic in a car of well-known make, which has a left hand drive.

* * *

Notwithstanding the impression conveyed by the newspapers that bricklayers are laying one brick a day, the construction of large new buildings for commercial purposes is steadily proceeding, and sectional engineers are kept busy in obtaining plans, preparing estimates, and wiring the buildings for telephones.

The number of the supervising staff in the external sections, whether on duty or pleasure bent, have always an eye open to note the commencement of the construction of a building, and at once seek out the architect in order to obtain copies of the plans. These plans are forwarded to the L.T.S. where they are marked with the probable number of telephones that will be required in each part of the building. The external and internal engineers then confer as to the best method of providing an adequate, flexible and economical system of wiring, and having submitted an estimate, and obtained Works Order authority, proceed to carry out the work. This procedure is mutually advantageous to the architects and the Department. Nothing can be more annoying to a master of his craft than to see it cut up as soon as it is completed. Architects now realise that telephones are essential to every business and as a rule are ready and anxious to make suitable provision for the cables that are necessary. Although the methods of wiring are standardised in principle, yet each building has peculiarities that must be considered, and it is not always easy to arrange the wiring so that the lowest average length of wire shall be obtained with the distribution cases in positions which are accessible to the lineman.

LONDON TELEPHONE SERVICE NOTES.

WEDNESDAY October 6 is the date to be remembered as that of the first meeting of the current session of the London Telephonists' Society. Mr. Beck has chosen as the subject for his presidential address "Some thoughts on Efficiency." "Efficiency" is a very broad term and associated with the word "some" as defined in the khaki dictionary, made many of us who read the bills a trifle uneasy lest we were being invited to one of those long and serious meetings in which traffic officers have been known to partake in the dim and distant past. Mr. Beck assures us, however, that we may dismiss our fears as in his dictionary "some" is interpreted as "a few," and he is trusting to his audience to make up the difference between "a few" and "enough."

* * *

The programme of the forthcoming session of the Telephone and Telegraph Society is not circulated at the time these notes are written; but it is safe to say that the papers to be read will prove of considerable interest both to telephone and telegraph specialists. Members of the London Telephonists' Society are again cordially invited to attend the meetings. The Chairman of the session is Mr. A. J. Stubbs and his opening address in which he will review the progress of telegraphy during the past fifty years will undoubtedly attract a large audience. The first meeting will take place on October 18 at 5.30 p.m., at River Plate House, Finsbury Circus, E.C.

* * *

The staff of the London Telephone Service are undertaking another large charitable work under the direction of Miss Heap. They are going to raise £1,000 with which to endow a "Telephone" bed in the South London Hospital for Women. The means to the end is a Christmas Fair to be held at the Memorial Hall, Farringdon Street, E.C., on Friday and Saturday, December 3 and 4. The Fair will be opened on the first day by the Viscountess Cowdray and on the second day by Mrs. G. F. Preston. The items which appear each month in this column are evidence of the manner in which the staff combine pleasure and social intercourse with endeavours in support of charitable institutions. The result of the last bazaar arranged by the London Trunk Exchange, when close on £1,000 was raised in a few hours, stands out prominently as evidence of the enthusiasm and success which attends these functions. The object needs no recommendation and there is every indication that Miss Heap's appeal to all members of the staff to contribute gifts and talent to the Fair is being answered with the customary energy which will undoubtedly ensure success.

* * *

The Langham Choral Society is opening its second season with a performance at the Queen's Hall on Tuesday, November 9, when Berlioz' "Faust" will be presented.

All who were present at the Society's performance earlier in the year will realise that this is an opportunity not to be missed, and they, together with those unfortunates who were unable to be present on that occasion.

THE STANDARD REFERENCE WORK.

AUTOMATIC TELEPHONY

By ARTHUR BESSY SMITH, E.E., Member A.I.E.E., formerly Professor of Telephone Engineering, Purdue University; and WILSON LEE CAMPBELL, E.E., Fellow A.I.E.E.

405 *pages*, 6 *x* 9, *fully illustrated.*

PRICE 24/- NET.

A comprehensive treatise on automatic and semi-automatic systems—the first volume devoted exclusively to this subject. It describes fully typical circuits and apparatus of each of the more important or instructive types on the market. It covers European as well as American systems.

CONTENTS.

I.—Trunking. II.—Automatic Electric Company's Switchboard Apparatus. III.—Subscribers' Station Equipment for Use with Automatic Electric Company's Two Wire Systems. IV.—Measured Service Equipment. V.—Automatic System of the American Automatic Telephone Company. VI.—Siemens and Halske System. VII.—The Lorimore System. VIII.—Automatic Traffic Distributor Equipment. IX.—Automatic District Stations. X.—Clement Automanual System. XI.—The System of the Western Electric Company. XII.—Long Distance, Suburban and Rural Line Equipment. XIII.—Cutovers and Interconnections of Manual and Automatic Offices. XIV.—Power Plant, Supervisory and Testing Equipment and Circuit. XV.—Traffic. XVI.—Development Studies.

McGRAW-HILL PUBLISHING CO. LTD.,
6, BOUVERIE STREET, LONDON, E.C.4.

Silk and Cotton-Covered H.C. Copper Wire.
Asbestos Covered Wire.
Charcoal Iron Core Wire.

will be well advised to secure seats as soon as possible as it is anticipated that the demand will greatly exceed the supply.

Tickets at popular prices will shortly be on sale at all Exchanges or can be obtained from the Secretary, Miss W. M. Nurse, West Traffic Office, 11 12, Norwich Street, Fetter Lane, E.C.4.

* * *

Contract Branch.

There were 914,924 stations on the Post Office system on March 31 last, an increase of 35,215 on the number in use on September 30, 1919. The growth of the London system during this period was 16,809 stations or 47.73 per cent. of the increase for the whole of the United Kingdom.

Before the war the stations on the London system comprised 33.4 per cent. of the total on the Post Office system: on September 30 this percentage had increased to 34.5 and on March 31 it showed a further advance to 35.

The London system, in spite of its large proportions, realised an increase at the rate of 11.06 per cent. per annum during the above period, the increases for the three largest provincial systems were as follows:—

Glasgow	... ...	8.04 per cent. per annum.
Manchester	... ...	8.66 „ „ „ „
Liverpool	... ...	6.24 „ „ „ „

The Contract Branch negotiated agreements for 3,403 stations during the four weeks ended August 28. The number of stations recovered during the same period amounted to 1,131, leaving a net gain of 2,271 stations.

* * *

Hop Exchange.

By means of weekly subscriptions spread over four months the sum of £10 has been contributed by the staff for the War Seal Foundation.

* * *

Kensington Exchange.

The staff have contributed by weekly subscriptions during the past six months £60 for the funds of the War Seal Foundation.

Trunk Exchange.

The Fifth Annual Swimming Gala was held at St. Bride's Baths on September 9. A very enthusiastic and appreciative audience numbered about 100. Two ladies sent by the Amateur Swimming Association acted as judges.

The following events took place:—

Beginner's race, won by Miss Coller.

Diving competition, won by Miss Powell, whose graceful performance was greatly enjoyed. Miss Hodder was a close second.

Graceful swimming, which also was won by Miss Powell.

Long Plunge won by Miss Harold, who nearly created a record.

The Club championship was won by Miss L. K. Davies with Miss Neville a close second.

The fancy races included Needle and Thread, Balloon, Cotton Gloves, Sunshade and Goodnight. The walking race was hotly contested by the Misses B. L. Webb and Balcombe, who tied four times before the final victory went to Miss B. L. Webb.

OBITUARY.

CORK. We regret to record the death of Mr. JAMES O'NEILL, Contract Officer, Class I, which occurred on August 28 last. Mr. O'Neill joined the service of the National Telephone Company in March 1905, and was very popular officer both amongst the staff and subscribers.

TECHNICAL BOOKS for P.O. ENGINEERS, &c.

EIGHTH EDITION. JUST PUBLISHED. TWENTIETH THOUSAND.

THE TELEGRAPHISTS' GUIDE.

By JAS. BELL and S. WILSON. Revised and brought up to date by a C.T.O. expert of high reputation.

It is not necessary to say much about this well known text book. Its value to students of Telegraphy is known throughout Great Britain, India, and the Colonies, and this new edition is worthy of its fame. Cloth 8vo, 255 pp. and 180 illustrations. **5s.** net, or **5s. 6d.** post free.

THE WESTERN ELECTRIC AUTOMATIC TELEPHONE SYSTEM. By B. O. ANSON. A well illustrated technical description which should be studied by all in the telephone service. Cr. 8vo, **1s. 2d.** net, post free.

THE HUGHES AND BAUDOT TELEGRAPHS. By ARTHUR CROTCH. Invaluable to students, as a knowledge of both systems is now demanded by the examiners. Fully illustrated. **2s. 9d.** net, post free.

ELECTRIC ACCUMULATORS. A clearly written and practical handbook of **160** pp.; well illustrated. **1s. 9d.** post free.

QUESTIONS AND SOLUTIONS IN TELEGRAPHY AND TELEPHONY. By H. P. FEW. Includes model solutions to the Grade I. C. & G. exams. **1904-1919**, as well as to typical questions set at the P. O. Departmental exams for Overserships. Fifth edition, **6s** net, post free

QUESTIONS AND SOLUTIONS IN TELEGRAPHY AND TELEPHONY FINAL EXAMINATIONS. By H. P. FEW. Set by the C. & G. Inst. in the final exams. in T. and T. for the ten years **1906-1915**, with full solutions to the last papers. Limp, Cr, 8vo, illustrated. **2s. 3d.** net, post free.

NOTES ON TELEGRAPHY. By PRATT and MOGG, Bristol. A simple exposition of the rudiments of Technical Telegraphy and Telephony. **216** pp. **126** diagrams. **2s. 9d.** net, post free.

TELEGRAPHY. By T. E. HERBERT. The Third Edition of this Standard Text-Book is Reprinting. Officially recommended by the C. & G. Examiners. Cr. 8vo, **1 000** pp., **630** illustrations.

STORAGE BATTERY PRACTICE. A practical handbook on the manufacture and properties of Electric Accumulators and their installation and operation. By ROBERT RANKIN, B.Sc., M.I.E.E. New and up-to-date. Cl. 8vo, **169** pp, **70** illustrations, **8s.** net, post free.

QUESTIONS AND SOLUTIONS IN MAGNETISM AND ELECTRICITY. By W. J. WHITE, M.I.E.E. Contains solutions to all questions in M. and E. (Grade I.) set by the Board of Educ. and the C. and G. Inst., for **1907-1913**. Fully illustrated. **2s. 2d,** post free.

AUTOMATIC TELEPHONE PRACTICE. By HARRY E. HERSHEY. Gives full details of the latest developments of the Strowger Automatic Telephone System. Cl. 8vo, **15s. 6d.** net, post free.

TELEPHONE TROUBLES AND HOW TO FIND THEM. On both the Magneto and Common Battery Systems. A very useful book. **9d.** post free.

THE PRACTICAL TELEPHONE HANDBOOK AND GUIDE TO THE TELEPHONIC EXCHANGE. By JOSEPH POOLE, A.M.I.E.E. (Wh. Sc.), New edtion, thoroughly revised. Recommended by the C. and G. With **580** illustrations. **13s.** net, post free.

STANDARD TELEPHONE CONSTRUCTION METHODS. By FRANK B. HALL. This book contains **250** full page drawings of standard materials and methods of construction; **280** pages of specifications and tables. No detail from sub-station to main distributing frame omitted. **24s. 6d.** net, post free.

TELEPHONE ERECTION AND MAINTENANCE. A handbook for the contractor and wireman. By HERBERT G. WHITE. Officially recommended by the C. and G. Examiners. Cloth, 8vo, **129** pp. **2s. 9d.** net, post free.

TELEPHONE APPARATUS. By GEO. D. SHEPARDSON. This is a handbook of Telephonic data for inventors, designers and manufacturers of telephonic apparatus as well as for installing engineers, exchange managers and superintendents. Cl. 8vo, **337** pp. and **114** illustrations. Price **18s. 6d.** net, post free.

MANUAL OF RADIO TELEGRAPHY AND TELEPHONY. By Comdr. S. S. ROBISON, U.S.N. A splendid text-book for Wireless Operators. Recommended by the P.O.E.E. Journal, The Electrical Review and the leading teachers. Fifth edition, revised and enlarged. **10s 6d** net, post free.

A B C OF THE TELEPHONE. A practical treatise for all who are interested in the subject of telephones. Covers the theory, practice, construction, care and management of telephones and their appliances. **352** pp., **264** illustrations. **6s. 6d.** post free.

HANDY ELECTRICAL DICTIONARY. By W. L. WEBER. Thoroughly up-to-date. Contains definitions of over **4,800** distinct words, terms, and phrases. Cloth, **1s. 8d.** net: leatherette, **2s. 8d.** net, post free.

ELECTRIC CIRCUIT THEORY AND CALCULATIONS. By W. PERREN MAYCOCK, M.I.E.E. **355** pages and **120** diagrams. Will be found useful in all kinds of electrical work. Deals with Electrical Pressure, Drop, Current, Resistance, Conductors, Ohm's Law, Power, Energy, Efficiency, Insulation-Resistance, Light and Illumination, Electric Heating Circuits, Systems of Charging, and so forth. There is a separate section on Arithmetic for those who are weak in "figures." Recommended by the C. and G. Examiners. **6s. 6d.** net, post free.

POST FREE AT ABOVE PRICES TO ANY PART OF THE WORLD.

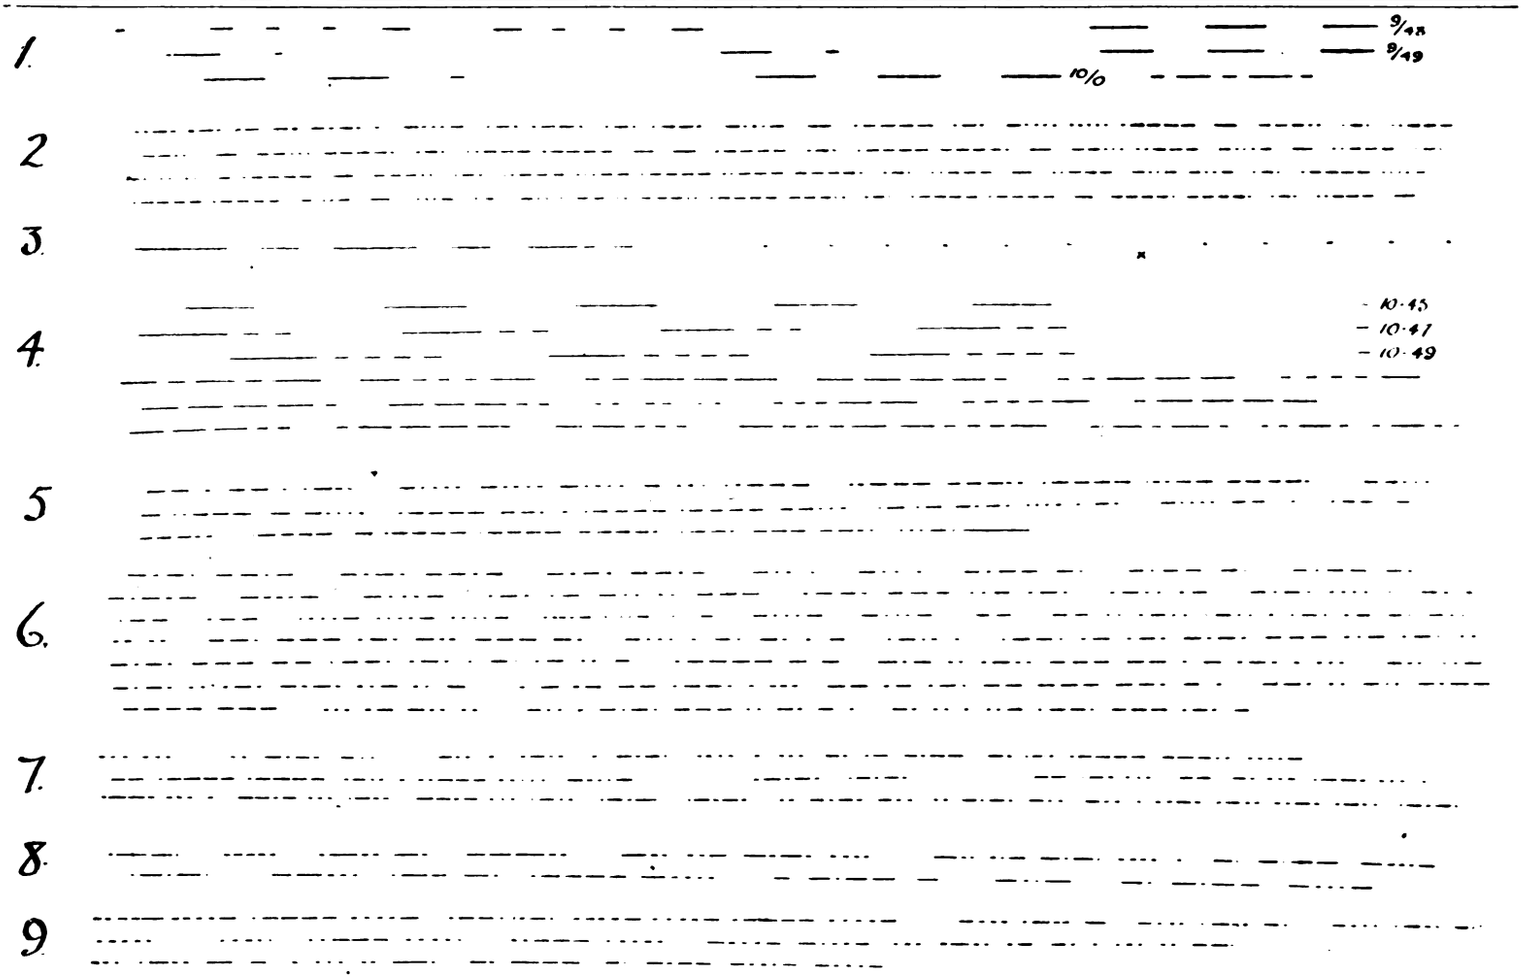
AUTOMATIC AND HIGH-SPEED WIRELESS WORKING.

By B. S. T. WALLACE (C.T.O.)

THE report of the Imperial Wireless Telegraphy Committee indicates the great advance made in this science during the past few years, and its tremendous possibilities. From a practical telegraphic point of view the most important achievement is the satisfactory accomplishment of high speed automatic working. For continuous and "difficult" traffic, such as would pass over a world-wide system of large wireless stations, this method of transmission is essential. Though not a new development, the advent of the thermionic valve has enormously facilitated and simplified automatic working, so that an ordinary wheatstone slip can be run through the usual transmitter and printed in morse or caused to operate a Creed reperforator, as on a line or cable. With the old spark systems there were two main difficulties to contend with. (1) The enormous power that had to be made and broken by the transmitter or special transmitter relay. (2) The extreme weakness of the received oscillations and consequent difficulty in operating any form of mechanical contact relay to close a local circuit. There remains a third obstacle, to be referred to later, that at times seriously interferes with all wireless working.

By virtue of a certain characteristic of the thermionic valve, modern high power stations can control an output of many kilowatts in a way that is easily handled by a slightly modified wheatstone transmitter up to its maximum speed. Reception is still mainly carried on by means of telephone receivers, the dots and dashes being heard in them as musical notes. Recording has been done photographically with the use of sensitive reflecting galvanometers, and also by means of the dictaphone, the records of the latter being re-run at a speed suitable to the transcribing capabilities of the individual operator.



All these methods are unsuited to modern conditions, competition with cables, and the creation of a new class of cheaper long-distance communication. Morse recording with ultimate direct type printing are imperative, and for this it is necessary to operate a contact relay similar to the P.O. standard instrument. This can now be done with less difficulty than formerly by what is known as the trigger relay action of the thermionic valve. Some idea of the extreme sensitiveness of this device, can be gained from the following illustration. With a valve, contact relay, and electric bell suitably connected, the bell can be rung by electrifying a piece of ebonite by friction with a silk cloth and holding the ebonite several feet from the thermionic valve. In fact, given a sufficiently dry atmosphere, it would be impossible to stroke a cat the wrong way anywhere near the apparatus, without ringing the bell!

The records illustrated in the photograph were printed at the author's experimental station, and give some idea of what can be done, bearing in mind they were produced by more complex arrangements than are necessary for the latest devices, owing to limited facilities in the matter of apparatus, &c. With the exception of Paris "time," the signals were all hand operated from the distant stations. The most striking feature is the absence of distortion or irregularities such as would probably be experienced on land lines and cables to the same individual stations. This point is well illustrated on a sounder. Wireless "marks" from any distance are reproduced accurately and as clear and sharp as on short circuit. I have seen a test wheatstone slip received by wireless at 400 words per minute. It was perfect.

There is, however, one great difficulty to contend with: interference caused by atmospheric and other electrical storms. Sometimes the phenomenon is quite local and due perhaps to thunderclouds, at other times it is world wide and attributed to some form of solar activity. The effect is analogous to a land line being in continual intermittent contact or under heavy induction. With such conditions recording is, of course, impossible, but owing to the musical notes of the various transmitters aural reception can still be carried on, provided the extraneous noises are not stronger than the signals. Conditions are at times so bad that it is necessary to send slow, and repeat each word twice. Many methods and suggestions have been tried for the segregation of these "stays," but the trouble is almost as bad as ever.

On the day these records were taken, there was a fair amount of minor static disturbance below the signal strength of the stations concerned and therefore causing no interference with recording in London. It would probably have been manageable up to a distance of 2,000 miles. Beyond this figure the strength of moderate atmospherics approaches nearer the received signal intensity and also another at present little understood factor creeps in: the variation in volume of the received signal itself.

Digitized by Google

Now the stations whose work is here illustrated, and many others, were transmitted over 3,000 miles, most of them experiencing difficulties even with telephone reception. There were frequent requests to "send twice" and "slower." In the early evening Nauen (Berlin) sent the following "note" to Madrid. "Cannot read anything owing to weak signals and atmospherics; stop sending; nothing Rd.; start again at midnight, very slow, once." This was in English, by the way, which is frequently used for service purposes by wireless stations of all nationalities.

There is evident wisdom on part of the Imperial Committee in confining their scheme to 2,000 mile stages. We all hope the Engineering Department of the G.P.O. who will be entrusted with the erection and working of the stations, will be able to supersede the performance of the various systems at present in operation, eventually overcome outstanding difficulties, and so establish a means of communication that will one day, put long lines and cables on the scrap heap.

The following details of the slips in the reproduction may be of interest:—

1.—*Paris (FL)* 2,600 *metre wavelength spark.*

New international time signals. The letter "O" is signalled after each of a series of "X's" (with curiously short dashes), "N's," "G's," the final dash of each "O" terminating exactly on 9.48, 9.49, 10.0 respectively, Greenwich mean time a.m.

2.—*Paris (FL)* 2,600 *spark.*

Portion of code weather report giving meteorological conditions for whole of Europe. The key is published and enables mariners, farmers, and anyone interested within a vast area of Paris, to obtain this useful information. Note the figure "O" is signalled by a longish dash. This is now a universal practice among wireless stations on other than ship work.

3.—*Paris (FL)* 2,600 *spark.*

Scientific dots. 360 are sent at 10.30 a.m. G.M.T. each 60th being missed to facilitate counting. The missing 60th is shown by the cross. They are sent for the purpose of checking chronometers by the coincidence method and ensure an accuracy of $\frac{1}{200}$th of a second. They have been of vital importance for determining the exact longitude in the survey of parts of Africa.

4.—*Paris (FL)* 2,600 *spark.*

Old time signals, still in use. A dot follows each of a preliminary series of "T's," "D's" and "6's," indicating respectively 10.45, 10.47, 10.49 G.M.T., a.m. Two groups of figures, repeated three times slowly for the benefit of observers unskilled in morse, follow this time signal.

They refer to calculations to be made in connection with the scientific dots sent 15 mins. previously, and vary daily.

5.—*Nauen (POZ) (Berlin)* 3,500 *metres wavelength. Spark.*

Portion of weather report giving readings from Memel and Aachen.

6.—*Lyons (YN)* 15,500 *metres wavelength. Continuous wave.*

Press for China and CQ 444 words, showing portion announcing Sadi Lecointe as the winner of one of the Gordon Bennet cup races.

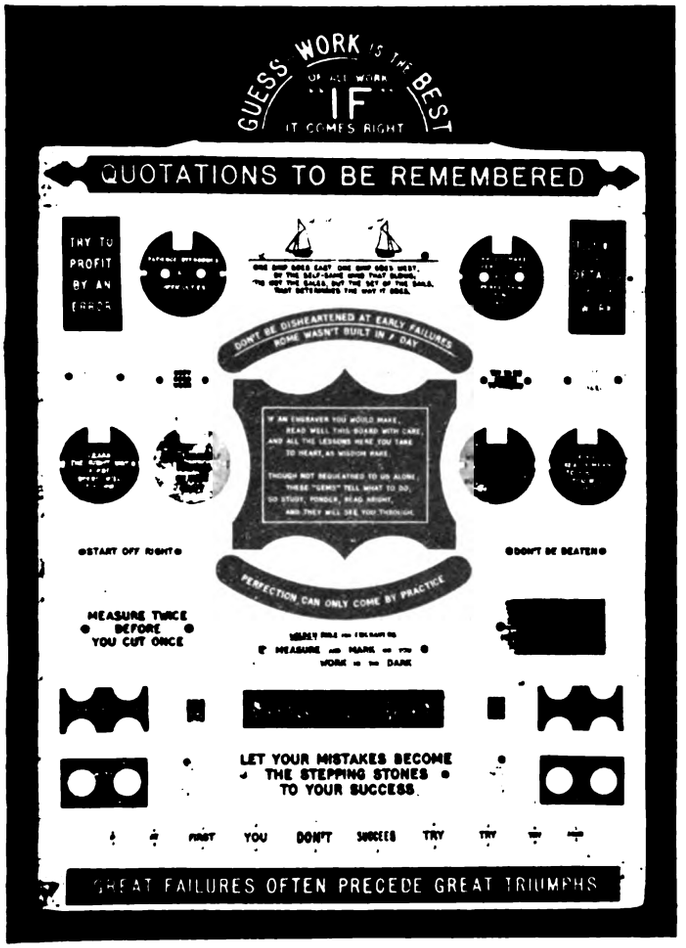
This particular message was a model of perfect morse and from the photograph it looks almost incredible that it could have been hand signalled

7.—*Paris (FL)* 10,000 *metres wavelength. Continuous wave.*

Preamble of commercial message from Lechesnay to I C D (Rome) and the request at end of message "Mrs pse Q S L" which interpreted liberally, means, "Send Rd pse."

8.—*Carnarvon (MUU)* 14,000 *metres wavelength. Continuous wave.*

Preamble of commercial messages L N (London) to N Y (New York.)



9.—*Nauen (POZ)* 12,600 *metres wavelength. Continuous wave.*

Preamble of message Berlin to New York showing each symbol repeated twice owing to bad atmospheric conditions.

As will be observed, ideal operators are on the key at all these large stations. They possess that vital quality "rhythm," their work is beautifully timed and spaced that it "goes like music" and "writes itself." Such a contrast to the fidgetty, soul-destroying, tarradiddle that is still allowed to pass as morse on too many of our land lines.

MACHINE ENGRAVING.

A board which the foreman of the Machine Engraving Shop at Holloway Factory has put together to be placed before learners and used by them when they are learning to operate the engraving machines. The idea of combining precept and practice seems a happy one.

THE BAUDOT—XIV.

By J. J. T.

BEARING in mind the construction and principle of the Baudot keyboard as already studied, we may now consider that portion of the apparatus known as the Receiver and which performs the important function of translating or converting the electrical pulsations into mechanical action, and thus into printed letters. As a first step it should be remembered that (whether in a Single Plate or Double Plate form of Baudot) the relay which repeats the signals into the Baudot receiver coils, only repeats the *marking* signals, the spacing currents being represented by their time value, *i.e.*, that period during which they hold the relay tongue against the Spacing Stop. This may seem an elementary point to accentuate, but the more expert Baudotistes will recognise the appositeness of the reference and the less informed will do well not to miss its importance.

A general view of the receiver was shown in the earlier articles last year. I am again indebted to the Indian Telegraph Service for photographs (Figs. XXXVI and XXXVII) of the same when opened out. Reference to these may prove useful as we proceed. The fact that the old-fashioned winding gear and base is shown in Fig. XXXVI instead of the more modern direct motor drive does not affect the description of the receiver itself, which remains essentially unchanged. Each receiver is fitted with five electro-magnet coils wound with fine insulated silk-covered wire to a resistance of 50 ohms, each coil being provided with a non-inductive shunt of 200, thus reducing the resistance to 40 ohms. Each of these coils (Fig. XXXVII A^1 to A^4 and Fig. XXXVIIIA) is screwed end-on to the inside of the back supporting plate 2 (Figs. XXXVI and XXXVIII).

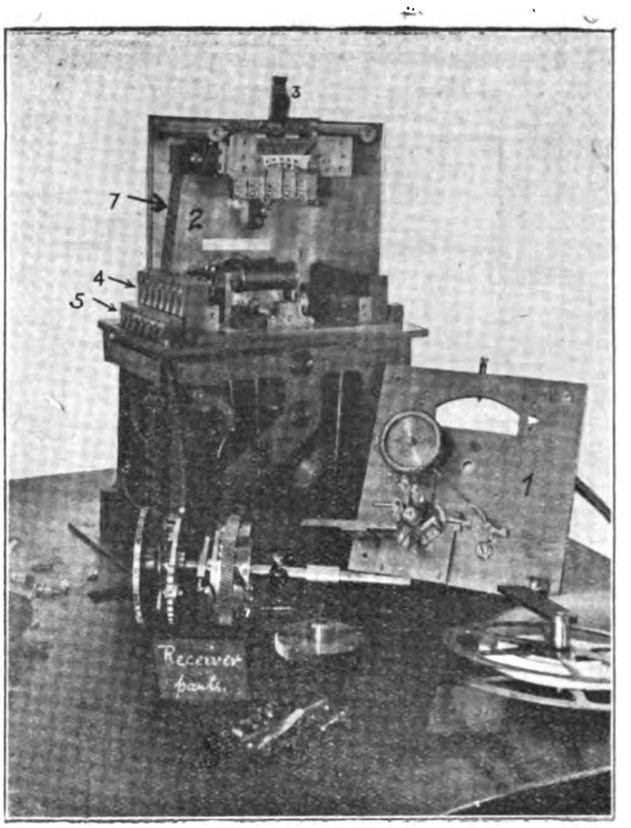

FIG. XXXVI.

Fig. XXXVIII gives a sectional view of part of the interior mechanism of the receiver with the printing axle X and C the combiner wheel, shortly to be described. The soft iron core E of the coil A projects outwards and terminates in an extended pole piece E^1. An armature E^2, hinged at H is slightly under-cut at its free end so as to present a maximum surface to the tapered pole piece E^1.

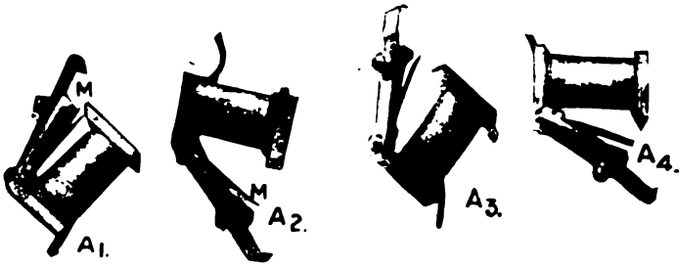

FIG. XXXVII.

The armature E^2 is also fitted, upon its under side, with a laminated brass split spring M (see also Fig. XXXVII), adjustable in its tension, which in addition to replacing the armature and appendages when the current has ceased to energise the coil, prevents actual contact between the armature and the pole piece E^1 when the former is attracted towards the latter. The detrimental effects of residual magnetism are thus avoided, and the rapid action of E^2 is therefore materially assisted, being of course aided still further by the shunting of the coils.

The electrical connexions are brought to a base block 5 (Fig. XXXVI) fixed on the base plate in the winding gear type of Baudot. In the direct motor drive type of receiver a studded strip connexion takes the place of the base block and is screwed up to the flat spring connexions 4 of the receiver, which latter form the normal and permanent equipment of all Baudot receivers. From the block 4 the connexions are led to the various parts of the receiver, the five coils being served by means of insulated wires fitted to the back plate 2 (Fig. XXXVI 7 → and Fig. XXXIX 7). The reverse ends of each coil are finally connected to the framework which in turn is joined to earth by simple contact with the base plate, itself connected with the main earth,

Digitized by Google

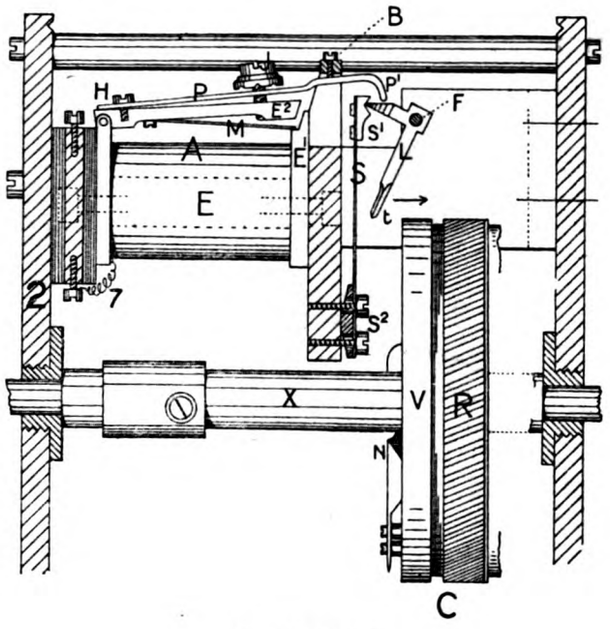

FIG. XXXVIII.

To the armature E^2 (Fig. XXXVIII) is fitted an "appendix" P (see also P^1 to P^5 Fig. XXXIX) adjustable as regards its distance from E^2 by a notched screw J, the notches of the latter locking the adjustment in any determined position. When the armature E^2 is at rest the lipped portion P^1 overhangs, but does not touch the lever L, known as the appendix lever (see also Fig. XXXIX). S. is a laminated steel spring fixed at S^2 and fitted at S^1 with a double slotted head piece. When P and its armature are quiescent, the nose of the lever L rests in the uppermost of the two slots; when the action of the armature E^2 draws P downwards the lip P^1 strikes L smartly and forces the nose of L into the *lower* slot of S. This movement results in the foot t of L being thrown out in the direction of the arrow, and towards the edge of the combiner wheel C.

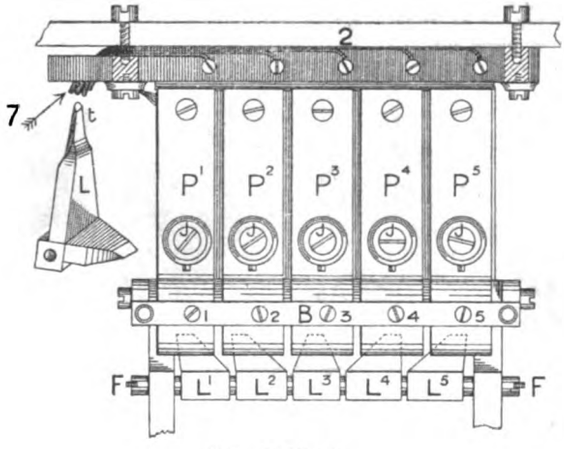

FIG. XXXIX.

Fig. XXXIX gives a bird's eye view of the five appendixes P^1 to P^5 with the respective levers L^1 to L^5 which they govern. One of these levers L is shown separately. It should be remarked that as the feet are arranged *radially* round the combiner wheel C Fig. XXXVIII (see also Fig. XXXVI just underneath the raised armature 3) they are not interchangeable as regards position on the spindled axle FF (Fig. XXXIX). See also F (Fig. XXXVIII).

A brass bridge-piece B (Fig. XXXIX) fitted with stop-screws 1 to 5 controls the upward movement of the appendixes and armatures when the electro-magnet coils are de-energised. This bridge-piece is also indicated in section Fig. XXXVIII where an individual stop screw B may be noted.

(To be continued.)

THE HANDLING OF TELEGRAPH TRAFFIC.

IT has come to be realised that Telegraph Traffic study has too long been delayed, and that there are potential possibilities which await application. It is only within the last decade that the question has been grappled with seriously. Some advance has undoubtedly been made, and there still remains much to be done if the Service is fully and adequately to meet the requirements and demands of present-day tendencies. If, as is anticipated, we are on the threshold of a new era in the history of the world, in that the conditions of life and work are about to be transformed—if that has not yet been already begun—everything possible that forethought can imagine must be carefully examined, in order that it may be ascertained along what pathway advancement can be made which will be for good. Already we have the production of science in the form of better and—from a manipulating point of view—simpler telegraph apparatus, but the question remains, are we utilising the facilities and the means of applying them to the best advantage?

It has been said that the basis of proper traffic study is the study of statistics, and I am not sure that it can be truly said the telegraph statistics have been adequately studied in the past. Through neglect of such study, it is feared that the economic factol in telegraph management may have been neglected. The conr sideration of costs is everything, and in studying costs statistica-investigation is the all important factor. This does not necessarily mean economic study with a view to saving of a purely parsimonious kind—such saving, after all, is not always true economy—but study of the most profitable means of adjusting staff in using the apparatus and plant provided, and what is even more important, study of the best means of handling the work. Even those who have taken but a superficial interest in the development of the Telegraph Service remember that, not so long ago, certain large towns worked a great number of Morse circuits to the Metropolis mostly by ordinary key signalling, while the admirable Wheatstone instrument was merely held in reserve. Think of the enormous maintenance cost of those wires! This is not indicated as a reproach, but merely to illustrate our tardiness in looking at things from a traffic point of view. Changes for the better have been, and are being made, and it is hoped that the course entered upon will be pursued, in order that a more expeditious and reliable service may be established.

While it has to be admitted that the flat tariff rate for the Inland Telegraph Service cannot be regarded as in any degree satisfactory from an economic point of view, and that such an arrangement as that which exists has sometimes restricted forward movement, it is more urgently necessary than ever before that the equipment should be the best and the most up-to-date. Only by maintaining the means by which quick and reliable dispatch can be maintained will it be possible to retain public confidence. Men of all professions and businesses not only require that, but demand it, because without it they are unable to keep in touch with the world markets, and to compete fairly therein. So soon as and not till unreasonable delay is eliminated, will business men and the public generally be satisfied. If, then, a quick and reliable service is to be given between all important commercial and industrial centres, equipment and channels ought to be provided to ensure the dispatch of every telegram within ten minutes of its receipt. If that were achieved, increased business would assuredly follow. Old ideas must be set aside if progress is to be made. Therefore, let us think less of reducing the number of channels and spare equipment, and concentrate attention on the full use of the excellent apparatus available. It is a pity, and I sometimes think a great mistake, that freer use is not made of the Wheatstone transmitter on busy circuits, where at present it is very often more ornamental than useful. That, of course, is due to the fact that it is not considered desirable to commence punching until the circuit delay is approaching 30 minutes. Co-operation between offices is asked for, but however willing and desirous all are to co-operate in expediting the transmission of traffic, it

Digitized by Google

cannot be done for the simple reason that no staff margin exists. A staff margin ought to be fixed at all large offices in order to permit the best possible use being made of Baudot and Wheatstone apparatus at all times, conjointly with Creed re-perforator and printer. When not required to assist at main points, such staff could generally be usefully employed at the concentrator switches or at other points. An alternative to the full and free use of Wheatstone would be the installing and extending of Baudot sets which, so far as experience has gone, is the most satisfactory high-speed arrangement for dealing with large volumes of commercial traffic. It is cleaner than any other, and admits of corrections being instantly dealt with. Manipulation of the apparatus is readily acquired—from six to eight weeks' training being sufficient to produce a good keyboard operator. Such apparatus, if introduced, which it ought to be at all suitable points, coupled with organised efficiency, would, I venture to believe, overcome many if not all the difficulties attending the expeditious and accurate transmission of telegrams. In this connexion it is fully recognised that the utility of typewriting machines in an Instrument Room becomes more restricted, but their value in connexion with the transcription of Morse slip and copying work generally remains, and their usefulness as a means of acquiring a knowledge of and a proficiency in keyboard perforator manipulation is as great as ever. Now that the abolition of office "C" copies is an accomplished fact, one more forward step in opening the way for the employment of typewriters in conjunction with Morse Sounder apparatus has been taken. Again introduce, wherever they can be used to advantage, mechanical message conveyors, and thereby assist in reducing the circulation delay. Superintending officers and staff cannot be too frequently reminded of the fact that it is of the utmost importance that telegrams should be collected from the baskets and circulated with a minimum delay. Anything beyond two or three minutes should be challenged if a firm grip is to be kept upon the circulation.

In every large telegraph office there should be a chart in every division showing the staff required during every half-hour of the day, and, if found practicable, the fluctuation of the traffic which should approximately at least be ascertained by exhaustive statistical study. By these and similar means, force could readily be transferred from one section to another without difficulty, and the waste which results from only transferring staff when congestion actually sets in at a particular point avoided. I am quite alive to the difficulties in the way of this, but I am not disposed to believe the idea to be impracticable. Let the best brains be applied to the problem, and I for one am hopeful. Every variation of the traffic must be studied, not quarterly, or half-yearly, but daily, and it would pay to employ a highly-efficient officer at all large offices exclusively on such work. The result would probably be that traffic would be dealt with more expeditiously than it is, and the whole organism would run more smoothly, both from a superintending and a staff point of view.

There are many problems and anomalies connected with the prompt delivery of telegrams awaiting solution. During the period of the great War, and even now, the want of a full complement of messengers has and is preventing an expeditious service being rendered. It seems to some extent to be wasted energy to effect improvements in the handling of traffic in Instrument Rooms, while delay in delivery at the booking-out point continues to exist. The present practice of batching is, from a business point of view, bad, and gives rise from time to time to serious complaint, not to mention losses to the business public. It shakes confidence in the Service and leads to the withholding of traffic which otherwise would be freely tendered. A messenger force sufficient to permit of every telegram being separately delivered is, therefore, necessary. A short study of local requirements would probably establish to what extent the messenger force required strengthening, in order to achieve the desired result. The present practice of delivering telegrams from Head Offices after 7 p.m. in large centres is still too expensive, and it is suggested that consideration might properly be given to the question of imposing a charge for porterage after 7 or 8 p.m., or the adoption of some other means to cover the cost of delivery. It is an inequitable arrangement that a delivery charge of 1*s.* per mile should be charged for the delivery of telegrams addressed to districts of a city which happen to be outside the postal area of the Head Office, while messages for other districts situated at greater distances are delivered free. Such anomalies can hardly be defended. For example, we have in Edinburgh a free delivery at all times to all districts, with the exception of Portobello, which, although nearer to the Head Office than Newhaven, Granton and Murrayfield, has an impost of 1*s.* per mile placed on each telegram requiring delivery after 7 p.m.

The whole position appears illogical, and the existing porterage charges so involved, that the question appears to open a field for inquiry and the application of the expert mind, in order that an expensive, if not wasteful, system may be superseded by one which would apply fairly all round.

It would be interesting and instructive were figures available for study as to the cost of the delivery of telegrams from the larger offices after 7 p.m., and from the smaller offices at all times. No doubt such figures would be illuminating, as showing the extravagance at present permitted. At the Edinburgh Head Office the weekly cost for tramway car tickets alone is approximately £5 to £6. If a similar expenditure applies to all large offices throughout the country and the cost of delivery from the smaller offices be added for purely day services, apart from the fixed wages or docket earnings of the messengers, the total additional cost would, I believe, be astonishing. All that could readily be saved by a justifiable re-adjustment of the limits of free delivery. The something for nothing policy must cease, and every activity of our national life be required to pay its way.

Then we have the delivery of telegrams by telephone, which is also an unremunerative arrangement and calls for at least modification. It is true that during the War period the Department, by a canvass of subscribers, to some extent solved a real difficulty which existed, but like many other War measures, at what cost! Can a continuance be justified? As a business proposition it cannot be defended, and now is the opportune time to set about bringing it into line with economic needs of the Service. The provision of confirmation copies was a bribe to induce business houses to accept delivery by telephone, but when it is considered that confirmatory copies are not sent to the Department by those who prefer to dictate their telegrams to the Post Office, there appears to be no cogent reason why they should require and be granted confirmatory copies of telegrams dictated to them from a Post Office.

Most, if not all, of the points dealt with have at one time or another been under consideration and therefore no originality is claimed for them, but each touches the basic principles of our craft and, unless they are dealt with on scientific lines and translated into every-day practice, the Telegraph Service will fail to meet the requirements of commerce and the general public.

All true Progressives would do well to lay to heart and put into practice at the present time the sage advice of one of the greatest of modern organisers: "I should say audacity is the thing for you. Think out new ways. Think out new methods. Think out even new ways of dealing with old problems. Don't always be thinking of getting back to where you were before the War. Get a really new world."

G. S. H. (Edinburgh).

CEYLON.

There seems a great shortage of watches and clocks in Ceylon if we may judge from the fact that as many as 800 calls a day were made last year by subscribers for "correct time," and that many subscribers repeat the request ten or twelve times every day. And as the measured service is not in operation the revenue receives no benefit from the added burden.

REVIEWS.

"Life Stories of Famous Men." Published by Watts & Co., 17, Johnson's Court, Fleet Street, E.C.4. Price per volume, cloth, 3s. 6d. net, in paper cover, 2s. net.

Under this title a series of volumes is being issued by Messrs. Watts & Co., descriptive of the life-work of some of the chief protagonists in the great struggle for freedom of thought and inquiry.

The aim of each of these volumes is not to produce a study or appreciation, but to furnish a pictorial presentment showing what manner of man the person dealt with was, just what he actually did, and what he strove to accomplish.

Each volume will contain four full page half tone portraits or illustrations.

The first two volumes of the series, dealing with THOMAS HENRY HUXLEY and AUGUST COMTE, are now ready. They are written in a pleasant style, and certainly fill a want in present day literature. Notwithstanding the amount of cheap reading matter which has been produced in recent years, very little biographical work has been published in a cheap form. The importance, from the educational standpoint, of knowing the history of really great men is very great, especially in an age when blatant self-advertisement is so often taken at its face value, without any thought as to how much genuine merit lies beneath.

We feel sure that the present series of volumes will be welcomed. They are well printed, and the illustrations are good.

Since the foregoing was written, we have received the third and fourth volumes, dealing respectively with ROBERT OWEN and CHARLES BRADLAUGH.

ROBERT OWEN was one of the leading social reformers of the first half of the nineteenth century, while CHARLES BRADLAUGH took a prominent part in the struggle for freedom of opinion, both in and out of Parliament, during the latter half of that period.

Both these volumes are well up to the standard of the first two in arrangement and in the interesting manner in which the biographical story is related.

Subsequent volumes will be devoted to DARWIN, VOLTAIRE, J. S. MILL, HERBERT SPENCER, THOMAS PAINE, HUME, DIDEROT, GIBBON, G. J. HOLYOAKE, R. G. INGERSOLL and RICHARD CARLILE. Others, not yet announced, will probably follow these.

"The Practical Electrician's Pocket Book" has been officially recommended by the City and Guilds of London Institute. This book was reviewed in our August number, page 179. (*S. Rentell & Co., Ltd. 2s. 6d. net.*).

Messrs. Siemens Bros. & Co., Ltd. have issued a new and enlarged edition of their catalogue (No. 537) dealing with Siemens' dry cells and batteries, and a new edition of their Pamphlet No. A550 about wireless telegraphy for ships.

We have received No. 4, Vol. 1 of *Radio Electricité* published at 12, Place de Laborde, Paris, 8dme Arroud. The cover as was to have been expected from our French colleagues, is thoroughly original, while not failing to appeal to the artistic. It is not clear at what intervals of time the periodical appears, but apparently each month. The production is excellent, the paper being of first-class quality, the type new and clear-cut, the diagrams and photographs beautifully reproduced, and in this respect vies with the *Wireless World* for first place. A photograph of General Messimy who is credited with an *initiative audacieuse* in 1910 whereby he utilised credits already voted and ear-marked for the erection and maintenance of telegraph *lines* by transferring these credits to the erection of a wireless net-work uniting Tchad, the two West African French Colonies and Equatorial French Africa. All's well that ends well. The scheme turned out for the best and proved of inestimable value during the War, providing the French with much needed apparatus. Much as one may admire the daring of the man, we most sincerely hope that there may not be many others like-minded in the French or any other administration so empowered as to be able to divert upon their own initiative funds allocated, let us say, to telephone re-construction and re-organisation, to works specially concerning the telegraphs, or *vice versa*.

A most valuable map of Africa is reproduced showing the present or projected local and inter-colonial wireless telegraph system, which comprises over sixty stations. The territory covered may be better realised when it is recorded that these stations are as wide apart as Djiboutl on the east coast, Dakar in the west, Tanger and Alger in the north, and Tamatave (Madagascar) in the south, not forgetting the new and more powerful post in construction at Tananarive.

There is much other interesting matter of general and scientific interest and one cannot conclude without reference to, what is rather unusual in a review, the beautifully attractive advertisement of "Les Accumulateurs Dinin pour T.S.F. 'pendant la guerre' and "en temps de paix." There are two photogravures typical of war and peace conditions wonderfully blended, while the whole is not aggressively advertising, the batteries just taking their normal proportion and place in the picture insinuating yet not intruding themselves upon the reader.

Readers will be glad to learn that Mr. Gunston is very much better. We hear that he has benefited so much from his sojourn at a South Coast resort that he is able to take mild exercise without undue fatigue.

APPRECIATION.

The following extract seems to conflict strangely with the journalistic views of certain week-end visitors to the United States; but it is reprinted without addition or alteration from the *Evening Standard*, of Sept. 24, and represents the opinion of Sir John Foster Fraser:—

Oh, but the London telephone system is much better than that in New York. If I have acquired any grey hairs during the last two years it has been due to being the victim of incompetent New York telephone operators. The machinery side is better in the United States; there are more telephones, and booths are plentiful; but the service is better in old London than in little old N'Yawk—at least that is how I've thought during my 24 hours at home.

COVENTRY.

The Postal, Telegraph and Telephone Society has been revived and the programme of papers for the 1920-21 season is as follows:—

Oct. 7.	"Scientific Illuminations," by Mr. J. R. Milnes.
Nov. 4.	"Authorship of Shakespearian Plays," by Mr. W. H. Oliver.
Dec. 2.	"The Night Relief and "Amongst" the Clouds," by Mr. H. T. Kirby.
Jan. 6.	"The Wonderland of the Wasps," by Mr. J. J. Ward.
Feb. 3.	"Postal Facilities in Egypt and Palestine During the War," by Mr. H. J. Wilkinson.
Mar. 3.	"The Experiences of a Telegraphist in East Africa," by Mr. R. W. Bingham.
April 7.	Short papers by members only. Prizes given.

Digitized by Google

THE OPERATOR'S VIEWPOINT.

THE following extracts from an article by Miss Lucille C. Selk in the *Telephone Engineer*, of Chicago, U.S.A., shows that it is not only in this country that subscribers are at times unreasonable in their demands on the operators.

If there is one individual in America who is getting more unfavorable publicity than an anarchist or a profiteer it is the telephone operator, and, land knows, the poor girl little deserves it!

Service complaints have become household bywords; jokes about Central's waning efficiency have crept into the newspapers and magazines and on to the moving-picture screen. When debates over the latest Senate shortcomings lag for street car travellers, there is always left the telephone girl on whom to let forth disgruntlement because she can no longer supply numbers as speedily and as bulkily as we demand them.

Attacks like these nettle her pride, but do not prick her conscience.

* * *

So when you hurl forth your customary, "Well, Central, did you finally wake up" or "Enjoy your nap?" remember that not for a second is the telephone operator off the job; that every ten feet apart there is a watchful overseer, who travels her ten-foot beat to see that every light, flash and flicker is answered within record time; that over every watchful overseer there is a more vigilant overseer to intensify the job of watching, and that over the vigilant one there are machines with still greater authority.

"But," says the public, "it took me five minutes to get Central on the line this morning, and then she gave me the wrong number and couldn't get the right number, and I knew they were there because I could see them from where I was standing, and when I did get them—finally—she cut me right off in the middle of the conversation. Why, the service is terrible!"

There are angel subscribers who are always satisfied with your service, there are subscribers who meet you halfway, and there are downright grouches who are never satisfied, no matter how hard you try to please them. Every office has them, every telephone girl is "posted" on them. Central knows that when Mr. Grouch's light comes up she must drop her half-finished connection and minister to the man who gets $100 worth of service each month for $2.

If a day passed without his calling the manager and giving him the usual diatribe, that day would be gala in the history of the office. He begins to flash before the receiver is off the hook. His voice is warped and shrill and pugnacious.

Failure to answer him within three seconds means "You reported!"

I have known subscribers who felt that securing the discharge of an operator whose ability to serve failed to coincide with their ability to demand was a sacred obligation.

* * *

The root of all antagonism between public and operator is the subscriber's failure to realise that besides himself there are thousands as eager to get their "parties" as he is.

When signal lights appear on a switchboard as thick as a patch of stars, it is mortally impossible to answer every calling subscriber in record time. Operators to the left and right of you are there with the long reach to help you out, but even then it is impossible to serve every one with equal quickness.

Fundamentally, local and toll are alike. Whether you are connecting parties in different streets or in different cities demoniac speed, flawless accuracy and unswerving courtesy are expected of you.

Mr. Business Man in Cleveland forgets that it may take an hour to locate Sam Brown in Chicago, that the operator may have to trace him from a dozen hotel registration books to golf links or winter gardens.

He thinks the operator can jab a plug in a jack, ring and have Sam Brown instantly report "Here!" as easily as you can get a response from that most obliging of all numbers— the police station. But not so.

Hundreds of other operators from different cities and states are all bent on the same game of "getting somebody's number;" and in the maze of circuits, out-lines, trunks and a thousand other technicalities there is bound to be a clash or delay.

* * *

Did you ever pick up your receiver and toss off casually: "Central, I have a list of numbers to call. See that I get a little special service, will you?" Of course you have.

But do you know that in order to give you that special service Central has to watch your light ahead of thirty others, must pop out "Operator!" the fraction of a second your light comes up must drop a half-finished connection and forget numbers on two other calls and miss her chance in the Main circuit to see that you have no cause for flashing? Then when she returns to her dropped parties and say apologetically, "What number, please?" she gets the weary advice to take the cotton out of her ears.

* * *

In the old days five minutes to get a number was a fair record. To-day the haste with which an operator is expected to answer is appalling. You say, "Gimme Fairchild 620."

"Fairchild 6—20?" says the voice with the smile.

Up in the exchange the operator makes a quick dash for your number, but before she reaches it Operator 20 to the right comes this way on a lurch, bent on getting 8000. Now 8000 is high and requires a reach which drags No. 20's shirtwaist three inches out of the belt. Operator 20 poises the tip of her cord on the rim of jack 8000, but before she can give it the little push that places it, down it tumbles, and the straining job of reaching has to be done all over again. She falls back to her position and you go on after 620.

The line tests revertible busy, but you know it can't be possible. You split the connection and test separately to make sure you don't give Mr. Subscriber the wrong report. Yes, it's a clear, busy test.

"The line is busy," you say pleasantly.

"What!" he screeches, "and it took you all this time to find that out? Well, good"—and he bangs the receiver up in your ear with a crash that makes the drum vibrate so rapidly as to nearly give out under the strain.

* * *

Yet the "hello girl" must smile—never laugh—just smile. If she comes in on the line with such an irregularity as a laugh on her lips, you infer it's no wonder "the service is plunk when those operators have time to carry on so!"

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. NOVEMBER, 1920. No. 68.

THE STANDARDISATION OF MAN.

WE are all familiar with the efforts made to standardise telegraph and telephone plant, efforts which are often disturbed by the genius of inventors which places at our disposal thermionic valves, high speed printing telegraphs, wireless telegraphy, automatic telephones and similar epoch-making diversions. We even appreciate the advantages of standard parts, especially if we happen to be changing a wheel in the dead of night when even the elements are weeping sorrowfully; and, possibly, we may have an earnest desire to see some great statesman introduce standardisation of weights and measures with a metrelitregramme. The modern schoolboy has no doubts on the last point when he is struggling with firkins, coombs and other commercial idiosyncracies, which in his mind were invented solely for his discomfiture.

We already have standard bread, standard suits, standard boots, which pinch non-standard feet, and we read standard books. But have we ever imagined that Nature, assisted by science, is perchance carrying out a scheme for standardisation of US. The prehistoric man recognised no laws; he was as profoundly unaware of his fellow creatures in the next valley as he was of the inhabitants of the antipodes. If the strenuous struggle for existence ever allowed him time to think, his thoughts were his own, and his manners and habits were likewise primitive. Civilisation and evolution, nature's own forces, have made great changes in man's environment. His servants, steam, electricity and petrol, the harbingers of speed, have annihilated distance. Man is no longer a biped with a circumscribed horizon but a winged amphibious animal who is tenant in possession of the heavens and the earth and the waters under the earth. The broadening of his sphere has made him more and more cosmopolitan. The same thoughts, the same foods, the same ideals and the growing knowledge of foreign languages are wiping out the differences between men of different nations. The need of universal service is for universal language. The English language, so Mr. Wallace tells us in this number, has become the general tongue of wireless telegraphists. Telephony, even more than telegraphy, demands one uniform method of expression.

International Telephony is as yet in its infancy; but when the day arrives for universal telephony, we shall be forced to adopt a common language. Our American friends have already found that telephonic intercourse is abolishing the territorial oddities of speech in their vast country. Local phrases are either being lost or absorbed in the general language; dialects are disappearing and speech is gradually becoming more uniform in timbre, tone and pronunciation. Is this not a sign of the forthcoming standardisation of language? Much as we might regret the loss of the refreshing speech of our friends north of the Tweed, yet, if constant telephonic intercourse between Aberdeen and Somerset is to be a thing of the future, both parties will have to abandon their peculiar and picturesque idioms and talk plain English. Sorrowful though the thought may be in many respects, we are being standardised. Differences in food, clothing, laws, thoughts and even speech are becoming things of the past and Dame Nature herself is in the front rank of those that standardise.

HIC ET UBIQUE.

A SHY and retiring man was advised by a friend to propose by telephone to the lady of his choice who evidently did not share his failing. The conversation is said to have taken the following form:—

"Is that you, Mary?"

"Yes."

"Will you marry me, dear?"

"Yes, rather. Who is it speaking?"

Punch rarely misses an opportunity of a gibe at the Telephone Service. A recent issue depicted a fat man in a call box with the legend:—

"*Caller*: Exchange! Get me double-six double-five nine Central—and get it quick like they do it on the pictures."

The fat man in the picture certainly does not deserve prompt attention as he is using the receiver as a telescope by applying it to his eye instead of his ear, and he has obviously not read the instruction to get his money ready. Moreover he seems to be bellowing into the transmitter in a way not calculated to secure good results.

Again, our amusing contemporary says:—

"The West Dulwich man who struck a rate-collector on the head with a telephone deserves credit for finding some use for those instruments."

I DON'T see how ever they know it
But picture-play actors all do it;
They don't have to look
In a telephone book,
But grab up a 'phone and go to it.

Telephone Engineer, Chicago.

LONDON TELEPHONE SERVICE NOTES.

THE opening meeting of the London Telephonists' Society was very successful although the number of members present was not so large as one would have wished, nor as might have been expected in view of the total membership. Perhaps the title of the paper "Some Thoughts on Efficiency" was not expressed in the most attractive terms, but, as the sages tell us, birds of attractive plumage are seldom good singers—the application is to the paper and not to its author—and those who were not present missed an interesting subject full of matter calculated to set many thinking. In the discussion newspaper criticism was given a larger share of attention than it deserves. The newspaper mostly tells tales of the harassed subscriber, and in his paper Mr. Beck enumerated attributes required by the harassed telephonist to carry her through her troubles with subscribers. The thought suggests itself whether the disagreeable features, real and imagined, of the telephone are responsible for the appellation "Hello Girl!" used in the press by friend and foe alike. The term appears to convey the suggestion of a place obtained "*via* Trunks" where, if reports are true, all residents are harassed. The public have generally quite an erroneous impression of many things telephonic, especially those which concern the interior of an exchange, and there seems to be some case for the education of the subscriber. Subscribers do not know, for instance, as one speaker observed, that telephonists are provided with little keys bearing various letters of the alphabet which can be used in combination for word making. The use of this facility by the operating staff has been suggested as an explanation of overhearing on order wires to *D*alston, *A*venue, *M*useum and *N*orth Exchanges. Whol knows ?

Mr. Beck's paper was not illustrated, but those who are interested wil do well to refer to the photographs appearing in the recent issues of this JOURNAL in connection with articles on the subject of the London Engineering District. There will be found illustrations of a rare species of Government servant, so far the personification of efficiency that in the September issue the suggestion is made that a collective photograph might be suitable for a poster advertising an efficiency exhibition which is being organised by a daily contemporary.

The next meeting of the Society takes place on Wednesday, Nov. 3. Two short papers will then be read, one by Miss M. H. Knights, of the Controller's Office, on "The London Telephone Directory," and the other by Miss A. M. Scott, also of the Controller's Office, on "Trunk Tickets."

* * *

All who are interested in the development of machine switching in London should not fail to attend the meeting of the Telephone and Telegraph Society of Nov. 15. The meeting will be held at 5.30 p.m. in the Hall, River Plate House, Finsbury Circus, which is close to Moorgate Street Station. On that occasion Mr. M. C. Pink is reading a paper entitled "Automatic Telephony in Large Areas." The installation of an automatic exchange in the Carter Lane building will, it is hoped, be commenced before very long. It will be known as Blackfriars, and will provide for about 3,000 subscribers and will constitute the nucleus of a machine switching system to serve the London Telephone Area.

During the course of next year our readers in the London Exchanges may expect to be wrestling with changes of operating practice consequent upon the application of machine switching to London, and also in connexion with the development of the Toll or short distance trunk system. An acquaintance with the problems which Mr. Pink will unveil will certainly be valuable. Tickets of membership of the London Telephonists' Society are available for this and all meetings of the Telephone and Telegraph Society, and it is hoped that there will be a very large audience.

* * *

The first season of the London Telephone Service Swimming Association had a fitting conclusion in a highly successful Gala, held at the Holborn Baths, on Oct. 7. A programme of 20 events was presented. It included an exciting water polo match between the Ravensbourne and Gresham teams, the former winning by three goals to two, and a splendid exhibition of diving by members of the Amateur Diving Association. Competition was very keen in all the events and especially in the five open to all members. The enthusiasm of the grouped supporters from the various exchanges put to shame the few men who were present and who had cherished the delusion that their own vocal efforts on behalf of favourite football teams represented the last or rather loudest word in partisanship. The Learners' Race was won in great style by Miss Borrows (H.S.), the next two places being filled by Miss Goddard (R.E.) and Miss Creed (E.) respectively. The manner in which this race was won made it excusable for one to suppose for the moment that Miss Borrows had mistaken the event for the next, which was the individual Championship of the L.T.S.S.A. There were three heats to the Championship race, the winner of each and the fastest loser swam in the final. A good race saw Miss Wilson (Gerrard Exchange) returned as champion. Miss Millbank (C.) was second and Miss Digweed (K.) third.

The "Pounds" Challenge Cup was won by the Gerrard Team after a very exciting race, in which the Central team led by about half a yard at the time Gerrard's last string entered the water. A battle royal ensued, Central being beaten by a few inches only. The Trunk team finished third but were disqualified owing to a too hasty take off by one of their strings, and the third place was consequently awarded to Kensington. The first prize in the Graceful Breaststroke Competition went to Miss Fisher (C.) who defeated Miss H. Davies (G.) by 36 points to 35. Miss Amos (VI.) was third. In the Diving Competition Miss H. Davies (C.) was first, Miss Amos (VI) second and Miss Fern (VI.) third. Not only was the diving of high quality, but considerable pluck was exhibited by some of the competitors who took a header from the topmost board. In the serious contests, calculated on a points basis, Gerrard Exchange were first with an aggregate of 11, Central second with 7 and Victoria a close third with 6 points.

The prizes were distributed by Mrs. G. F. Preston. The first season of the Association has been an undoubted success, due to that enthusiasm which is so prominent a feature in the staffs of our exchanges. The officers of the Association and the members of the several clubs are to be congratulated and we wish them even greater success next year.

* * *

There's many a true word spoken in jest. Is the reference in the Personalia column of last month to Miss Symons, of Victoria Exchange, as an Assistant *Superintendent* an instance ? ["The wild waves!" ED., T.&T.J.]

* * *

Contract Branch.

It recently came to light that two Limited Liability Companies were using the same Private Branch Exchange with which some Unlimited Service lines were connected. Enquiries revealed the fact that the two Companies were not identical and as is usual in such cases, Joint User rates were pressed for. The following is an extract of a letter received from the Company who were the original subscribers in respect of the Private Branch Exchange in question.

"The chief difficulty appears to be that the two Companies have separate Directorates. In order to obviate this we have arranged for the present Directors of (the second Company) to retire, which they have already done, and at a general meeting which will be held at these offices on Tuesday next the same Directors will be appointed on the Board of (the second Company) as are now on the Board of (the first Company). The two Companies will then have the same Board of Directors, the same offices, the same staff and will use the same Banking account and we presume this will get over the difficulty. You will understand, of course, that we are not in any way attempting to evade the payment of any dues to which we may be liable, but at the same time we do not wish to pay a heavy additional annual charge through a technicality."

Of course ! ! !

* * *

It is generally assumed nowadays that telephone subscribers in the City of London are aware that they have solemnly entered into an agreement not to remove or damage in any way the instruments or fittings which have been fixed by the Department. It may surprise some of our readers to learn that a caller at the City District Office recently brought with him a wall set neatly tied up in a brown paper parcel and calmly informed the Enquiry Clerk that he had decided to give up the line. In fairness to the operating staff it must be added that the subscriber's action was not due to any delinquencies on their part.

The Contract staff frequently have to exercise a great deal of ingenuity in ascertaining the requirements of correspondents. The following letter illustrates the point:—

Just few lines to ask you could let ours have telephones on shop for the bussness. An exchange to —— West India Dock Road. But get some nder in my shop befor just want to put box on will you soon you as possible.

X.X.X.

The Contract Branch negotiated agreements for 3,791 stations during the four weeks ended Sept. 25, 1920. The number of stations recovered during the same period amounted to 1,448, leaving a net gain of 2,343 stations

* * *

City Exchange.

A most successful Bazaar, Concert and Social was held by the City Exchange staff at Stationers' Hall, Ave Maria Lane, on Oct. 9. The stately hall made an admirable setting to the bazaar, which was opened by Mrs. Inge, wife of the Dean of St. Paul's. In a charming speech she expressed her pleasure in making closer acquaintance with her neighbours in such happy circumstances. The object of the function was to raise money on behalf of the War Seals Foundation and so enthusiastic were the workers and so appreciative the supporters that the sum realised will approach £300. The concert and social were thoroughly enjoyed by a large audience and the whole function was pronounced excellent. Great credit is due to the Organising Committee and specially to the Secretary, Miss Nicholson.

* * *

London Wall Exchange.

In response to the appeal of the London Hospital for contributions, a collection has been made among the staff and the sum of £20 raised on behalf of that deserving institution.

* * *

Trunk Exchange.

The Imperial Swimming Club held a very enjoyable Social Evening at the Sunday School Union on Oct. 12. Miss Beaumont, President of the Club, kindly undertook to distribute the prizes which had been won in the Gala held on Sept. 9. The Captain and Secretary, the Misses Temme and Hodder, were each presented with a small token in appreciation of their services. The musical part of the programme was left in the able hands of the Misses Flint and Walder, vocalists, and Miss Grist, monologues. Thanks are due to Miss Ruffy who acted as M.C., and to the Misses Longman and L. Smith, pianists, who contributed so largely to the success of the evening.

LONDON ENGINEERING DISTRICT NOTES.

Institution Meeting.

The London Centre of the Institution of Post Office Electrical Engineers held the first meeting of the Session at the Royal Society of Arts on Monday, Oct. 11, under the Presidency of Mr. J. M. G. Trezise (Chairman of the Centre), when the Engineer-in-Chief, Sir William Noble, read a Paper on "Telegraph and Telephone Engineering in the United States." Among the many distinguished visitors present were Sir Evelyn Murray, Secretary of the General Post Office, the Engineer-in-Chief of the New Zealand Telegraph and Telephone Service, and Mr. Addenbrooke. As Sir William stated it was not possible in the time at his disposal to give a detailed account of all the many interesting technical developments of telephone and telegraph work in America, and his paper was a *resume* of the outstanding features which most impressed him during his visit in 1919.

No one questions the fact that America has played a larger part in the development of telephony than any other country, and visits by experts from the British Post Office such as took place last year cannot fail to have beneficial res lts. The pity is that America is too far away to permit of very frequent visits or to enable large numbers of the staff to gain first hand knowledge of the telephone system of the States. Perhaps, when it has become common practice for the Atlantic to be flown in the time set by the late Sir John Alcock and Sir F. Whitten Brown, the Department will arrange week-end tours. Sir William paid tribute to the extraordinary pains taken by the officials of the various man ufacturing and operating companies in the States to make the visit a success. Some even gave up Sundays and public holidays in order that the visitors should not lose any time. Naturally the subject to which most attention was given was automatic telephony, and Sir William was so impressed with the Western Electric Co.'s panel system and its suitability for large cities that he made arrangements for the purchase and installation of a 3,500 line exchange which will be installed in the Carter Lane premises, London, which building already contains the City, Central and Trunk Exchanges. Several other important features of American telephone practice were dealt with in the Paper, such as line construction and long distance telephony with the help of thermionic valves, and the instructiveness of the lecture was greatly enhanced by numerous excellent lantern slides.

One of the most satisfactory references in Paper was that although America has a greater number of clever Telegraph and Telephone Engineers than there are in this country, she has none more clever than those in the Engineering Department of the British Post Office. Those present at the meeting left the Hall with a feeling that they had added to their store of useful information and with the intention of applying the added knowledge whenever possible and so justifying the policy of the Department in sending officers across the Atlantic.

* * *

Underground Cables.

The passing of Mr. J. T. Langley, formerly an Assistant Engineer in the London Engineering District, revives memories of the time when he took part in the laying of the first long-distance underground paper core cable in England some twenty years ago. This cable was laid between London and Birmingham, and many engineers of the older school solemnly shook their heads when they heard of the decision to proceed with the venture. The result was so successful that other cables were soon put in hand and the growth of the underground cable system became rapid. With the extension of the system came improvement in methods based on the experience gained, and on the research work which was carried out in the Engineer-in-Chief's Office and elsewhere.

There is a vast difference in the characteristics of the original Birmingham cable and the cables which are now being laid. The difference in efficiency is comparable to that in the design of the pre-war battleship and the modern super-dreadnought. The introduction of the loading coil and the telephone repeater had made it possible to use conductors of considerably less weight per mile with a corresponding increase in the number of conductors in each cable, the increase amounting to 500 or 600%. In order to obtain and maintain this efficiency, however, it is necessary to observe special precautions in the jointing and to make somewhat elaborate tests during construction and subsequently. The Engineer-in-Chief has been paying special attention to this matter and has arranged training courses for those who will be engaged in supervising the construction and maintenance of the cables. These officers are given instruction in the theory and practical work of balancing cables and in methods of testing which will enable a fault to be discovered before it has developed sufficiently to interfere with commercial speech. Of course, when the first underground cables were laid, it was not known in what direction the line of development would be and the methods adopted, although considered a high standard at the time, were much below those obtained to-day. Efforts, however, are being made to bring the older cables up to the modern standard so far as it is possible to do so. It is quite possible that twenty years hence someone, in a moment of curiosity, will turn over an old volume of the TELEGRAPH AND TELEPHONE JOURNAL and seeing this note will smile and wonder why the reduction in the weight of conductors was not effected sooner. There is no doubt that but for manufacturing and jointing difficulties a conductor lighter even than those employed on local lines at present could be used. If metallic conductors are used at all in those coming times, probably they will consist of a slight metallic deposit on a strip of paper, many thousands of these strips being subsequently laid together to form a cable. We do not know yet how the manufacturing and jointing difficulties will be overcome nor how the increase of electrostatic capacity will be neutralized, but he would indeed be a rash man that would be prepared to stake his reputation upon the assertion that finality in telephone cable construction has been achieved.

* * *

Pneumatic Tubes.

A number of extensions to the pneumatic tube system are now being made and others are in contemplation. These works involve long lengths of tubes being laid under the ground and in subways and also additional apparatus at the terminations. Owing to the necessity of keeping the tubes perfectly cylindrical very great care is necessary in handling them. Any dent or flattening which is not discovered before the ground is filled in results in the stoppage of a carrier, and it is sometimes a very difficult matter to locate the exact point of stoppage due to such a cause. It is much more easy to locate a definite break. For many years it has been realised that the traffic capacity of pneumatic tubes could be increased if a satisfactory method of signalling could be introduced which would indicate automatically when the tube is ready to receive another carrier. Various devices of the trigger type have been tried and rejected. Experiments are now being made with a device in which no trigger is employed. The passage of the carrier past a certain point causes a variation in pressure on the two sides of a diaphragm which is connected with the main tube by a bye-pass. Movement of the diaphragm completes an electrical circuit and causes a signal to be given at the outgoing end. The result of the experiment is awaited with interest. If it is entirely successful much relief should be experienced during the busy periods.

* * *

Threading Pipes.

How many men who use the term "Ratting" for the process of threading a wire through underground pipes are aware of the origin of the term? At one time it was the practice to tie the end of a ball of light twine to the body of a live rat and then to put the rat into the mouth of the pipe that it was desired to "thread." The rat (sometimes) ran along merrily to the distant end, drawing the light line after him. As soon as he emerged at the distant end he was pounced upon and the light line was used to draw in a heavier line. A few years ago attempts were made to force a form of carrier through a pipe by air pressure, the carrier having a light line attached, but it was not successful and this and other experimental methods have been abandoned in favour of the use of sweeps rods, which, although slow, is reasonably sure. It is possible that in the intervals of working out what the pay should be under the present bonus system some one may find time to invent a device which will enable a draw wire to be quickly threaded through empty and partly filled pipes.

* * *

Claims for Damage.

Apropos of the paragraph which appeared in a recent number of this JOURNAL re Claims for damage by vehicles to the Department's plant, an officer attached to the section dealing with the cases has drawn attention to the remarkable fact that the damage is never done by a vehicle travelling at a greater rate than five miles per hour. Occasionally a less speed is quoted, but not often, so that there appears to be need for an enquiry into the special circumstances attending this rate of travel. It is curious too, that although a constable is sometimes prepared to swear that 10 seconds before the accident the vehicle was travelling at the rate of 30 miles an hour the driver will swear (drawing upon an extensive vocabulary) that at the time of impact the speed had dropped to the magic standard rate of five. Probably there is some mysterious emanation from telegraph poles and linemen's trucks which is ineffective at a lower high rate of speed, but which will inevitably attract towards them a motor or trap driven at five miles an hour. There are persons who cannot understand the need for a Ministry of Transport nor what its functions should be, but what body could undertake a research into this singular phenomenon so well as a Ministry of Transport.

* * *

A Wayleave Episode.

One of the most important things to be done before any engineering work is commenced is to see that all wayleaves for operations on private property are in order. In this connection the story is told of two linemen who were about to run some wires from a pole which had recently been erected on private property. Whether the pole had been put up without the proper consent having been obtained we are not told, but just as the men were about to commence, the owner of the field appeared and asked them who gave them permission. The leading hand was speechless for the moment owing to the fact that he had not got the requisite authority with him. His mate with more presence of min i said "Show the gentleman the paper, Bill," and the former, acting on the suggestion, showed the proprietor the written instructions of his Engineer to proceed with the work. Without saying any more the latter went away, and the two men congratulated themselves on getting so well out of an awkward predicament. A few minutes later a fierce-looking bull walked into the field and at once made for the scene of operations. The linemen hastily climbed up the pole for safety, while the bull with plenty of time to spare leisurely took up his position at the foot of the pole, content to wait for his victims. Time went on but no-one appeared to relieve the situation. At last the two unfortunates saw the owner of the fiel i in the distance and loudly hailing him, they called on him to take the bull away. "That's all all right," was his reply; "Show the bull the paper, Bill."

Digitized by Google

Presentation.

The retirement of Mr. C. J. Hathaway, the Section Mechanic, was the occasion of a pleasing ceremony at Denman Street on the Sept. 30. The Sectional Engineer, Mr. A. Wright, in the presence of a representative gathering of the Staff gave a *resume* of Mr. Hathaway's highly creditable and valued services both with the Department and the late National Telephone Company. A handsome carved oak barometer (suitably inscribed) and a case of silver-mounted pipes, were tokens of the esteem in which Mr. Hathaway was held, and these were presented by Mr. Wright on behalf of the staff of the South Internal Section. In his reply, Mr. Hathaway asked that his thanks should be conveyed to his late colleagues for their kind recognition and good wishes.

Outing.

The photograph, a copy of which appears above, was taken at Sunbury-on-Thames on Saturday, Sept. 25, on the occasion of a steam-launch excursion in which 60 members of the Mechanics and Linemen Staffs employed at the Central Telegraph Office took part. Messrs. Strawson, Mellows and Pemberton were also of the party. It is pleasing to record that the arrangements were carried through without a hitch. After an excellent dinner, provided by mine host of the Weir Hotel, an adjournment was made to a field close by, where sports were held and prizes distributed to the winners. After tea an impromptu concert was given and the party then made for home after a most excellent day. Such functions do much to cement the friendship already existing between the two staffs, and our hearty thanks are due to those gentlemen who made the outing possible.

* * *

The Denman Chess Club.

The first meeting of the newly-formed Chess Club took place on Wednesday, Oct. 13, when about 30 members were present. The Club has been formed in connexion with the London Engineering District, the officers being as follows :—

President	...	A. Moir, Esq., O.B.E.
Vice-Presidents	...	J. E. Taylor, Esq., G. F. Greenham, Esq., J. M. Shackleton, Esq., J. H. Stanhope, Esq., A. E. Cooke, Esq., F. Freeman, Esq., and W. J. A. Payne, Esq.
Committee	...	Messrs. W. D. Frewin, H. J. B. Francis, A. J. Nevill, and H. Barrett.
Match Captain	...	C. W. Cornwell.
Hon. Treasurer	...	J. E. T. S. Hilton.
Hon. Secretary	...	E. H. M. Slattery, from whom all particulars can be obtained.

A very attractive programme has been arranged. In addition to ordinary matches, a tournament and a competition on Cup Tie principles will be held. It is also hoped to fix up matches with other service Chess Clubs.

TELEGRAPHIC MEMORABILIA.

THE Triple Baudot Duplex trials between London and Berlin appear to have been indefinitely postponed, as, with the present heavy traffic, and the at times indifferent working of the existing restricted telegraphic communications between the two countries, there is obviously no margin of time available for experimental use of any of the present working Anglo-German conductors, while staff shortage also adds a factor on both sides of the North Sea to these adverse circumstances. Nevertheless, it is quite plain that the communications are not at present up to their pre-war efficiency.

It is not to be inferred from the foregoing that the German authorities are unalive to the needs of Anglo-Continental telegraphy. The working of these circuits from a diplomatic point of view leaves little to be desired, and it becomes more and more evident that the main causes are electrical and technical. Apropos of this relationship with Germany it is with some degree of regret that one notes the removal of Herr Kunert from the repeater office at Emden. This regret is mingled with satisfaction at the promotion of this highly efficient officer to the position of *Postrath* of Oldenburg, and it is certain that others of those than the writer who came into direct contact with Herr Kunert when he visited this country will tender congratulations to a telegraphic engineer whose mind was particularly open to well-reasoned scientific facts and opinions.

While still on matters cablegraphic it is interesting, if curious, to note that while the Inland Telegraphs traffic curve is on the downward tendency the Anglo-Foreign curve abounds with peaks of considerable altitude, South American traffic to and from Europe figuring somewhat markedly. The Anglo-German traffic increase is measured in percentages of three figures.

Still lingering in the neighbourhood of the Cable Room, one passes to matters of comparative local interest where it is pleasurable to place on record a letter from the Secretary of the Hospital Saturday Fund, acknowledging with special thanks the sum of over £38 collected from this department.

Opening on to a matter of a wider sphere it is with very special pleasure that publicity is given to the "C.T.O. Games Fund for Benenden Sanatorium." This fund was started as a result of a few words in letters received from a Benenden colleague suggesting that a supply of games and music would be greatly appreciated. A committee of four aided by a band of enthusiasts at once set to work, and by means of a "Penny Collection" quickly obtained a sum of over £17. Perhaps other offices would kindly copy. Of this nearly £14 was at once expended on the re-covering of the billiard table, a supply of chalks, tips, wafers, also half-a-dozen cues, dominoes, chess, table bowls and cribbage boards have also been added. The average population of the Benenden institution is about 100. Above all things it is necessary to provide all the possible adjuncts to creating a cheerful atmosphere. The institution itself cannot possibly provide these "extras" on account of the present economical situation, and an appeal is therefore made on behalf of our less fortunate colleagues for further assistance towards what is now to be known as the Benenden Games Fund. Miss M. B. Jamieson, Cable Room, C.T.O., and Mr. R. E. V. May (Local Secretary of the P.O. Sanatorium Society) would be only too glad to receive donations. Will our telephone friends help with a penny per head collection please ? No apology is offered for taking up so much space for a laudable purpose.

It is certain that much interesting matter will be compulsorily held over this month, but space must be made for just a passing reference to the Autumn Flower Show of the C.T.O. Amateur Gardener's Assocation, and to the aquatic display by both sexes of the same office, in which the ladies played no mean part. By the way, it is recorded that the Deputy-Controller was "well in at the finish." Thus do our *young* folks recreate themselves after office hours !

Was it not Lubbock who wrote, "The advantage of leisure is mainly that we may have the power of choosing our own work, not certainly that it confers any privilege of idleness." Most certainly our telegraphists are able to take their pleasures strenuously and judging from all accounts of the water display, they take those pleasures with no trace of intermingle of that sadness with which foreign critics are reputed to have credited us as a nation.

In a well known electrical journal there recently appeard a remarkable example of the "marvellously small" and the "marvellously great." On one page was printed a description of certain apparatus, manufactured by a firm of electrical engineers in South Norwood, known as the Vernier Potentiometer 1920 pattern (Tinsley & Co.). The lower range of this delicate instrument is from one-millionth of a volt to ·190100 volts, and is, of course, used for thermo-electrical work and similar low E.M.F. measurements. Turning to another page in the same issue one could not help being struck with the contrast between the tiny power above indicated and the giant strength of the new electrically-driven battleships of the U.S.A. Each of the propellors of these giant vessels is driven by two eight-wound rotor Westinghouse motors, rated at 22,500 h.p. each. It is estimated that the electrical power developed for all purposes in any one of these leviathans (189,000 h.p., or 160,000 k.v.a.) would be sufficient to drive all the electrical railways of London !

A member of the Indian Goverment Telegraph Service from Akyab, recently passed through the London office and gave excellent accounts of Baudot working in India and Burmah. He informed us that the authorities were endeavouring to cut out repeater offices as unhealthily situated as is that of Akyab by utilising two wires instead of one. A first trial was being made on the Calcutta-Rangoon lines. Our visitor stated that the results of the experiment would not be known for some time.

The change-over from summer to winter or from winter to summer-time is generally associated with some little confusion in international telegraphy, especially if one of the countries is situated a considerable distance east or west of its correspondent, or where for this or other reasons one country or the other commences the alteration some days or weeks prior or subsequent to its telegraphic neighbour. Then there arises the problem of, for example, how to induce the distant office to open his circuits one hour earlier than scheduled time. This with difficulty having been more or less arranged, the next problem is to reciprocate (with a limited staff) at the *other* end of the day by prolonging the circuit hours by a corresponding period. By this

Digitized by Google

time the limit of staff attenuation is fairly well reached. Fortunately, this echelonned arrangement of working hours only lasts two or three weeks, but it is a perplexing phase while it lasts.

The existence of the "George Montefiore Foundation" prize is apparently little known, but it consists of the accumulated interest on 150,000 francs invested in 3 per cent. Belgian Stock, and is awarded every three years for the best original work on "Progress and development in the technical application of electricity." The 1921 prize, actually the postponed 1917 one, is of the value of 20,000 francs. As the essay may only be written in French or English there may be an opening here for some of our engineer readers. The latest date for the receipt of competitor's contributions is fixed as April 30, 1921. Full details and information may be obtained upon application to M. le Secrétaire, Association des Ingenieurs Electriciens de l'Institut Electrotechnique Montefiore, 31, Rue St. Gilles, Liége.

At a lecture some time ago telegraphist listeners received something in the nature of a shock when they learnt from the words of wisdom which flowed from the platform that what they had been taught to consider as fundamentally right and immovable in their youth regarding the direction of the current in an electrical cell was in fact fundamentally wrong, the simple reason being that experiments had produced irrefragable evidence that the current actually moved in the reverse direction. We were all recovering from this shaking of our faith in the ancient verities of the cult of Slingo, when our attention is directed to an article appearing in the *Electrical Review* (Aug. 6). Therein Mr. E. Raymond Baker dilates to the extent of three columns upon the unsuitability of comparing the properties of telegraph cables by the "cable constant," which so many of us had viewed as at least one of the few impregnable rocks. Most readers will recognise our old friend, the K×R law. There are others of us who, willing to be converted to the "new school" are also perfectly willing to surrender the thought that, judged by the results sometimes obtained, there always has been the lurking idea that other factors than these two mentioned should not be left out of consideration, more especially in the case of long multiple core submarine cables.

Fairly recent oral examinations, to which some of our telegraphist and telephonist colleagues have submitted themselves, have apparently been experimentally based upon certain psychological facts. For the benefit of these and other possible "victims," the following excerpts from Moede's *Praktische Psychologie* are submitted in abbreviated form in order to test:—*Attentiveness and the correct grasping of instructions*: A map or diagram is exposed to view for $\frac{1}{25}$ of a second several times. The candidate has then to write out all he or she has seen! Here is another test in which our craftsmen should shine. Simultaneous acoustic and optical signals are made, and whenever certain combinations occur the candidate is to press a switch or bell-push. *Response to stimuli*: A ball is rolled down an inclined plane while the attention of the examinee is occupied observing other distractions. The rapidity with which he is able to divert his attention to stopping the ball in its descent is a measure of his alertness. *Intellectual capabilities*: The candidate is read to, afterwards being examined as to his general conceptions of the document or documents. Psychotechnical examinations have been carried out by the Charlottenburg Psychotechnical Laboratory regarding the suitability of apprentices by testing the powers of judgment, "by setting an angle of the feel, by grouping together a number of metal discs of different thicknesses, and of poise and certainty." These by the aid of the *tremometer*. One feels rather glad that one's age has reached that respectable figure where the imposition of an examination of this type may be looked upon as a really remote contingency.

On Oct. 12, the occasion of the unveiling of the stone memorial presented to Great Britain by the Belgian people as a mark of grateful appreciation for hospitality and other kindnesses during the Great War, messages were exchanged between Mr. Collignon, Chief of the Antwerp office, and his staff, and the Controller of the C.T.O. M. Collignon is well known to some hundreds of telegraphists in London where he manfully and loyally worked as a simple telegraphist during those fateful months which succeeded the flight from the Belgian port.

There was a happy quintette of old pensioners round one of the tables recently within the hospitable precincts of G.P.O. North Dining Club, which brought news of other pensioners whom they had met during their hours of leisure and travel. Of Mr. Mayfield, formerly of T.S., still flourishing in his 80th year, for example! By the by, a very happy thought inspired a specially affectionate souvenir which was forwarded by a number of old T.S. friends to Mr. John Russell—"Jack" Russell, of the scarlet handkerchief cult!—on the completion of four-score and one birthdays. To Mr. H. A. Hodgson, of the Cable Room, sincerest congratulations upon his promotion to an Overseership. Mr. Hodgson's technical qualifications should prove specially useful in his new sphere of activities.

At the invitation of the "Secretary's Office Cricket Club," Messrs. W. T. Cook, A. W. Randall and T. P. Wilmot of the C.T.O., assisted the above club in two interesting matches—G.P.O. *versus* Shepherds Bush—played respectively on Sept. 23 and 30. The first meeting ended in a victory for the "Bush" by a narrow margin. The second encounter resulted in a draw very much in favour of the G.P.O. Cook, who has been awarded his Surrey Second Eleven Cap, played an excellent not out century innings and was ably supported by Hurford, who also played a good innings. Had time permitted the capital bowling of Reid, Hurford, Young and Randall would undoubtedly have disposed of the Shepherds Bush side and given the G.P.O. a win, but failing light caused the match to be undecided.

Both games proved very enjoyable, and it is more than a pious expression when the sincere hope is placed on record that this is only the first of similar invitations to be extended to C.T.O. cricketers.

On Oct. 1 at Holborn Baths a large gathering of the staff of the C.T.O. and their friends assembled to see the Swimming Competitions in connexion with the "Centels" Athletic Club. It was a historic event, not only in that it was a revival of a series of events which have necessarily been interrupted by the war, but also by reason of the fact that the ladies of the staff took part in the competitions. The divisional team competition for ladies gave rise to much interest, and spectators in the galleries encouraged the rival teams with cheers, which indicated a sense of loyalty to their divisions which was more than impressive. The organisation of the whole event was never at fault and once more we had a vision of the many-sided interests and accomplishments of a staff which is as enthusiastic in play as it is in work. All work and no play is clearly regarded, both by Jack and Jill, as falling short of the ideal. A list of the results will be interesting.

100 YARDS BREAST-STROKE CHAMPIONSHIP OF CIVIL SERVICE.

1st F. V. Hodge, Centels (Holder of Bennett Cup, 1920-21).
2nd L. S. Histead, Customs.
3rd G. W. Tripp, Ministry of Pensions.

Time—1 min. 29⅘ secs.

30 YARDS VETERANS' HANDICAP.

CORRESPONDENCE.

WAR SEAL FOUNDATION.

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

DEAR SIR,—The valuable work done for the War Seal Foundation by the staffs of the London Telephone Exchanges leads me to crave of you space for a short appeal to their provincial colleagues to emulate their example.

At the personal suggestion of Miss A. A. Heap (Superintendent, Female Exchange Staff) the staffs of the London Telephone Service have been brought face to face with the work of this organisation by a series of visits paid at different times to War Seal Mansions at Fulham and, realising the National importance of its work, have contributed quite a large sum in order to help it forward. The actual sum raised to date is £2,040, and this splendid result has been achieved in various ways. Some Exchanges have had weekly collections; others have contributed by purchasing War Seals at a half-penny each or in special envelopes containing 24 seals for 1*s*. In every Exchange—and in this matter we think London does not hold the monopoly—there is a great deal of vocal and instrumental talent amongst the staff and this has been turned to good account by organising concerts and other entertainments which have been run either by the Exchange as a whole, or by individual members of the staff in their own home neighbourhood. Bazaars, whist drives, sales of work, etc., have been most successful indeed. In the case of the bazaar held by the Trunk Exchange, I understand that assistance was received fom the provinces.

Believing that the Telephone staffs throughout the United Kingdom have just as warm hearts and are equally talented as their London confreres, I venture to suggest that during the coming winter most, if not all, of the provincial Exchanges would like to put forward some effort in order to forward the work of this Foundation.

To advertise through the usual channels is costly and not always effective, but every person who buys and uses a War Seal both contributes a half-penny to the scheme and advertises it. Had every person who last year posted a letter—irrespective of post cards and parcels—in the United Kingdom, affixed a War Seal to that letter we should have raised over £7,000,000. Such is the power of a half-penny.

To-day we have seventy-two disabled Service-men gathered *from all parts of the country* living with their families in War Seal Mansions and obtaining the after-care and treatment necessary to their well-being and comfort, and at this moment I have more than 200 applications for tenancy which I am unable to satisfy.

The pathos of these appeals and the distress revealed in them is so great that early this year Sir Oswald Stoll—our Founder and President—decided to abandon a scheme for the building of a theatre on his property which adjoins the site of War Seal Mansions—the freehold of which, by the way, he gave to us—and, instead, has handed over to us the freehold of the land whereon to build a further 65 flats, should sufficient funds be forthcoming.

It is difficult to bring home to the general mass of people of this country the awful consequences of modern warfare on the minds and bodies of a large number of the men who were engaged in it. The worst cases and the most pitiful are such that they are never seen in our streets because they are too ill to be moved. For many of them what remains of life must be one continuous round of suffering. It is impossible to keep these cases in hospital because the very fact of continued separation from those they love only increases their misery. Add to this the fact that there is a serious shortage of housing accommodation and you have a conjunction of circumstances which prove almost unbearable to those who are so disabled that they are unable to earn anything wherewith to augment their pension.

That this Foundation is doing a work of national importance is proved by the fact that last year Queen Mary, accompanied by Princess Mary, visited our flats, saw and spoke with the tenants, and afterwards told me how delighted she was "To see the men so comfortable in their own quarters and with their own people around them."

Supervisors or individual members of staffs are cordially invited to communicate with me, c/o The War Seal Foundation, 10, Charing Cross Road, London, W.C.2, when I shall be pleased to answer any inquiries and be prepared to make suggestions.

The matter is urgent. Please do something now.

Thanking you in the hope that you will grant space for this letter.—Yours faithfully,

WM. J. ROBERTS,
Secretary.

September, 1920.

TO THE EDITOR OF THE "TELEGRAPH AND TELEPHONE JOURNAL."

Dear Sir,—I enclose herewith copy of a letter received from a subscriber which will probably be of much interest to the readers of your Journal.

The actual difficulty was that the subscriber's line was in contact with No. 802.

The letter will give you some idea of the difficulties to be overcome by those managing telephone concerns in the East.—I am, Dear Sir, yours faithfully,

J. A. ROWLAND KNOX,
Acting Manager, Oriental Telephone & Electric Co., Ltd

Madras, *Sept.* 9, 1920.

Dear Sirs,

Re: TELEPHONE SERVICE LINE NO.....

We have to bring to your notice that when we have had a Table Telephone line at No..... which has given us very difficult in speaking, so we had to erect a Wall telephone at our premises No..... for which also we have not had any ready call, and cannot get early reply from the Exchange, if we want to ring up, highly into greater speed.

When we call the Exchange at your Office it has taken 10 or 5 minutes time, and do not know the course. In that case, if we ring highly then only replies cannot get immediately, and also gives much defect and trouble for our business purposes.

When we want to speak to our Branch Office telephone No. 572 we cannot get them soonerly, and in the meantime, the man can go easily, instead of calling in telephone, and seems very much hard to go in the line.

Having experienced all these difficulties, we had telephoned to the Clerk in Charge No..... but after making the complaints for three times, then he came, and seen the defect, but we did not know what he has done in the telephone.

Moreover, we also heard there are some other Firms who are speaking with the other connections.

We suppose the telephone No. 802 is in more connection, with our wire, and also we do not know the defect in our lines, and request you to rectify it by return.

Under the above said circumstances, kindly order your representative to go on here and see the defects at an early date.

Trusting you will do the needful in the matter.—Yours faithfully,

WRONG NUMBER.

We often hear people complain about wrong numbers, blaming the operators for carelessness and inattention to their work. It is not always the operator's fault.

The other day a man visited these offices and, desiring to be called later in the day, left his personal card with his telephone number written on it. When the number was called it was found to be a lunch room, and the man who left the card was in any business but that of a lunch room. He had transposed the figures of his number.

If a man can't give his own number correctly isn't it possible for him to transpose the figures of other numbers? Wrong numbers are not always the fault of the operator. *Transmitter*, Baltimore.

Aberdeen.

Mr. Storrie, the District Manager, on behalf of the staff presented Mr. JAS. MUNRO with a couple of pictures, and Miss ELSIE R. WATSON with a case of fish knives and forks, in view of their respective approaching marriages.

* * *

Plymouth.

Mr. C. W. DICKINSON, Clerical Assistant, was the recipient of a framed copy of a famous picture on the occasion of his promotion to Third Class Clerk and transfer to the Surveyor's Office, Exeter. He carried with him the congratulations and goodwill of the staff.

* * *

Rochdale.

Mr. JOHN ASHTON, late District Manager for the Rochdale Telephone District, who retired from the Service on Sept. 30 under the age limit, was one of the early pioneers of telephone work in England. He commenced his telephone career at Preston in 1881 with the Lancashire and Cheshire Telephone Exchange Co., Ltd., and became District Manager over 30 years ago. He has served in Preston, Blackburn, Ulverston, Newcastle-on-Tyne, Worcester

Newport, Cardiff, Leicester, Oldham and Dublin. Upon the acquisition of the system by the Post Office, he was appointed to the newly-formed Rochdale District in 1912, in charge of which he remained up to his retirement.

Mr. Ashton is a Lancashire man, born in 1860, his family connexions being with Preston and Blackburn. As evidence of his widespread popularity, it may be stated that he was presented with a gold watch, a case of pipes, an illuminated address, a photographic group of his staff (represented above), a barometer and a silver cigarette case. Mrs. Ashton was the recipient of a silver chatelaine spectacle case.

Sheffield.

The District Manager's staff have recently had the opportunity of showing their goodwill in a practical manner to no less than three of their clerical colleagues who undaunted by the housing and other difficulties of the present day have entered into the state of wedlock.

On Aug. 13 Mr. H. GILDER of the Traffic Department, was presented with a mahogany timepiece. Mr. Ferguson, the newly-appointed Traffic Superintendent, made the presentation and was cordially received.

On Aug. 27 the recipient was Mr. G. A. HARRIS, of the Contract Department, and the gift, an oak timepiece, was handed over by Mr. Thyne, the Chief Clerk.

On Oct. 8 the presentation of another clock was made by Mr. Thyne to Mr. W. LAING of the General Office.

* * *

Headquarters.—Mr. H. JULIUS MACLURE, Inspector of Contract Departments, has returned to the Post Office after 5½ years of loaned service with the War Office and Ministry of Munitions.

"EVENTS OF THE WEEK."

IT is not entered at Stationers' Hall nor has it "over a million sale." In fact its total circulation amounts to one copy. Edited by the Rising Junior, it is published every Saturday morning.

Its readers are the travelling members of a provincial Traffic Staff. From their little "Weekly" they learn what is happening in the whole district, what other members of the staff are doing. From the abbrevitated items presented them is obtained knowledge which is useful when visiting exchanges.

The little Journal is nothing to shout about. Its conception is not new nor claimed as such—but it's useful, and—it's a link.

Here is a recent copy.

J. C.

For retention. *Traffic Section.*

No. 66.

"EVENTS OF THE WEEK."

Week ending Sept. 18, 1920.

Colchester.—2 Trunk junctions authorised; additional record line proposed; additional phonogram circuit proposed; Admiralty circuit Bradwell; Walton line to be taken off Colchester local exchange.

Manningtree.—Proposed new C.B.S. switchboard equipped for 40 lines agreed to.

Burnham-on-Crouch.—New C.B.S. switchboard applied for $\frac{5+20}{45}$.

Wivenhoe.—10 additional indicators and jacks fitted.

Laindon.—Existing board to be replaced by C.B.S. $\frac{5+20}{45}$

Ipswich.—Additional multiple "hundreds" end position approved.

Long Melford.—New switchboard applied for $\frac{5+40}{45}$

Marks Tey.—New switchboard authorised $\frac{5+20}{45}$

Brentwood.—Secretary agrees provision of additional 100 lines switchboard.

Braintree.—Proposed date of transfer of exchange Sept. 28, 1920. (9 a.m.).

Staff Revisions in hand.—Dunmow, Bishop's Stortford, Manningtree, Witham.

Call Offices.—Opened, Clacton-on-Sea, P.O.; authorised, *nil*; proposed Felixstowe (Station Road).

Saxmundham-Leiston.—Aldeburgh intermediate circuit divided at Leiston.

Chelmsford.—Miss E. D. Dyke, temporary telephonist takes up duty at Colchester on Monday; Miss Harding, telephonist, resignation received.

Colchester Trunks renumbered in proper sequence.

(Sd.) TRAFFIC SUPERINTENDENT.

A RETROSPECT.

THE recent disastrous fire at the Hop Exchange, that lofty building to the south of the South Eastern main line from Charing Cross as it nears London Bridge, takes the thoughts of the writer back to the time when the National Telephone Company's Hop Exchange was actually in the Hop Exchange, whence it derived its name. He well remembers how as a lad he looked with a feeling something akin to reverence upon the then District Engineer (now a Provincial District Manager) who was credibly reported to have climbed down one of the stack pipes from top to bottom of the lofty building already mentioned.

The "Hop" Exchange is one instance of many in London where the name of the Exchange has lost its original significance. Probably the number of subscribers connected with the Hop trade forms but a very small proportion of the total number of subscribers on the Exchange in question. The name, however, being such a good one from the operating point of view "sticks," and apparently it will still remain in spite of the somewhat wholesale scrapping of time-honoured names in connection with the coming of the Automatic System. "Lee Green" is another case in point. The Exchange is at Lewisham and is at least three-quarters of a mile away from Lee Green where it was formerly established. The most notable instance of this, however, is the well-known Avenue Exchange, so called by virtue of the fact that it was originally installed in premises on the south side of Leadenhall Street known as "East India Avenue." The name was retained on the removal of the Exchange to Lime Street, and still more recently on its removal to its present *habitat* in Creechurch Lane.

When the writer entered the service of the National Telephone Company, something over a quarter of a century ago, there were in London twenty-five Public Exchanges, and of those only one is still in the same building in which it was then installed, and that is the Bank Exchange, so interestingly described by Mr. J. Webb in the August issue of the JOURNAL. This exchange was then known as "Queen Vic." Of the remaining twenty-four, some have been completely closed and exist neither in name nor in the form of exchanges substituted for them in the same locality, although one can only wonder whether the development of the service may not in the whirligig of time necessitate the establishment of new exchanges in the same districts. Cases in point are King's Cross, Kilburn, Balham and Clapham. In other cases the old names have gone, remembered only by a few, but the exchanges themselves have been replaced by others near at hand, *e.g.*, Coleman Street has long since been merged in the London Wall Exchange, Holborn took the place of Chancery Lane and Smithfield. Edgware Road is now known as Paddington, Heddon Street as Gerrard, and Deptford as New Cross. On the other hand, in the case of one of the existing exchanges, viz., Westminster, all the subscribers connected therewith were at the time of the transfer of the National Telephone Company's undertaking to the State diverted to one of the exchanges of the latter, *i.e.*, Victoria. The same thing is, of course, equally true of some other exchanges, but these were established at a later date than those with which the present article deals. It might also be recorded that in the meantime other exchanges have come into, and passed out of, being, *e.g.*, Holloway, Peckham, Barking, Harlesden and Hornchurch.

It must not be supposed, however, that because there were then districts in which no exchanges were established, such districts were necessarily without the Service. In some cases this was true, but in others Service was given to the nearest exchange, e.g., Tottenham was served from East, Highgate from King's Cross, Ealing from Kensington, and so on.

In those early days it was not necessary on calling a subscriber to quote the name of the exchange to which he was connected but to call by number only, the operator receiving the call being able by the initial cyphers of the number asked for to find the exchange with which the called subscriber was connected. In other words there was only one series of numbers for London, the numbers being allocated to the exchange in blocks. Had circumstances permitted the perpetuation of this condition of affairs how interesting would be the fight between the big commercial houses for Number One. This number was then in use by a firm of City merchants, a partner of which was a leading spirit in one of the earlier Telephone Companies.

Digitized by Google

The groups of numbers in use for the principal exchanges were as follows :—

Coleman Street	...	1 to 900.
Avenue	...	1001 to 1500, 2001 to 2500, 4001 to 4500, and 11001 upwards.
Queen Vic.	...	1501 to 2000, 15001 upwards.
Chancery Lane	...	2501 to 3000
Westminster	...	3001 to 3400
Heddon Street	...	3501 to 4000, 35001 upwards.
Hop ...	...	4501 to 5000, 45001 upwards.
East ...	...	5001 to 5400
Smithfield	...	6501 to 6900
Kensington	...	8501 to 8900, etc., etc.

Another interesting feature of those early days was that in addition to the alphabetical arrangement of subscribers in the Telephone Directory, there was at the end of the book a numerical list giving the name of the relative subscriber against each number.

As illustrative of the growth of the Service, it is interesting to note that the whole of the work in connection with the compilation of the London Telephone Directory was then in the hands of one lad, who was also responsible for issuing all Advice Notes (or Works Orders as they were then called); that is, he carried out the duties now performed in the Directory and Installation Sections of the London Telephone Service, the two together employing over seventy persons at the present time. It is hoped that this statement will not meet the eye of a certain telephone "expert," or it is feared he will bring it forward as an argument that State control of the Telephone Service means a much larger staff than would be employed by a private company.

It is often contended that rates were much simpler in those days, *i.e.*, before the introduction of the Message and Measured Rates, but in actual practice such was not the case. Even then there were three rates in vogue (1) the Ordinary Unlimited Rate. (2) a special reduced rate for private houses, which was only applicable in cases where a connection was rented at business premises. This rate was then applicable anywhere in London under the conditions mentioned, but was later altered to apply to private residences in the County of London area only, and the restriction as to a business connection elsewhere was withdrawn, (3) a local rate providing for unlimited service on one particular exchange or group of exchanges, with payment of a junction fee for communication with subscribers connected to other exchanges.

In each case the basic rate was for connection under a yearly agreement, subject to 5 per cent, 10 per cent. or 15 per cent. reduction respectively as a 3, 5 or 7 years' agreement was signed.

A table (or pedestal, as it was then more generally described) instrument was charged at a higher rental, 10*s*. in the case of direct exchange circuits, or 10*s*. 6*d*. on extensions. The apparent reason for the differentiation was that the annual charge was two guineas for an extension wall instrument and two and a half guineas was a better figure than £2 12*s*. to quote for an extension pedestal set. On one occasion a caller at the office, in as great a hurry to get the service as some people are nowadays, on the various rates being explained to him, elected to pay the additional charge for a pedestal set on the ground that he could take the instrument back with him and so have the service at once without waiting for a fitter to come and fix the apparatus as would, he thought, be necessary with a wall instrument.

A tremendous advance has been made in connection with Call Offices. Subscribers could, at that time, on paying a deposit of 5*s*. each, obtain any number of keys up to five. These keys enabled them to obtain free use of any Call Office in London. The coin collecting box was much more cumbersome than the pattern now in general use, the exchange being notified by means of a stroke on a bell gong instead of by buzzer. The stroke on the bell was given either by a coin dropping on to the gong or by a hammer, actuated by the key inserted in a slot provided for the purpose on the front of the box, striking the gong. This arrangement lent itself to various forms of trickery. Keys were forged. Pennies were bored and a double string inserted through the hole, enabling the penny to be lowered on to the gong, giving the necessary signal, and then withdrawn for use on subsequent occasions. The front of the coin collecting box was not entirely wood, but pieces of perforated gauze were inserted in front of the bell gongs. In this gauze persons of an economical turn of mind would make holes of sufficient size to permit of a knife or other metallic instrument being inserted to strike the gong and so give the desired signal to the exchange.

Much more might be written as to the changes and developments which have taken place in the last quarter of a century, but enough has been recorded here to show that *tempora mutantur*. It is hoped too that *nos in illis mutamur*. W. G.

THE BAUDOT—XV.

By J. J. T.

When any one or all of the appendix levers L are thrown forward by the action of the armature E^2 (Fig. XXXVIII) we noted that the foot, t of each individual lever thus actuated was thrown forward towards the edge of the rotating selection disc V of the combiner wheel C. Fig. XL, by means of dotted lines, shows the *active* position of a single lever L together with a completed view of the interior of the receiver and its front containing-plate 3, beyond which the axle X is seen to extend. This latter extension X^1 carries the type wheel and certain accessories. Reverting to the appendix levers: Fig. XLI gives a back view of the selection disc V showing all five appendix levers, L^1 to L^5 in their relative positions behind the disc. The dotted circles below the lettering represent the axle-ends of five more levers about to be described, known as *selectors*, shown C^1 to C^5 Fig. XLIII end-on, and in front-view see Fig. XLII. The selecting disc V rotating clockwise and solidly with the combiner wheel C and its axle X carries a

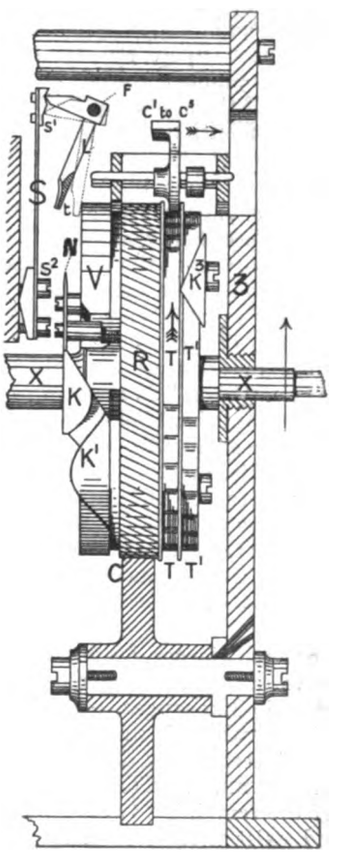

Fig. XL.

Digitized by Google

projection N (Figs. XL, XLI and XLIV) which guides as many of the appendix levers as may have been thrust forward into a curved channel, which, the rotation continuing, leads the appendix levers thus selected up to the apex of the cam K, but immediately the cam K^1 (Figs. XL and XLI) leads the feet of these levers out again, the rejecting impetus thus given throwing each lever back against its respective spring S (Figs. XXXVIII and XL) and into

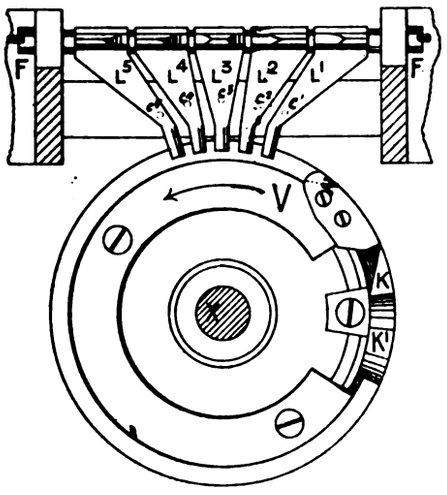

FIG. XLI.

its position of rest in the upper slot ready for the next signal. Each lever, however, in its passage through the curved channel upon reaching the apex of the cam K has been led so far *forward* as to butt up against the axle-end of the selecting lever or selector immediately in front of it (Figs. XL to XLII).

These *selectors*, C^1 to C^5 (Figs. XL to XLII), are of peculiar shape, and each carry a trailing foot. They are each capable of

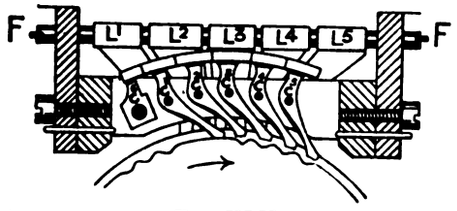

FIG. XLII.

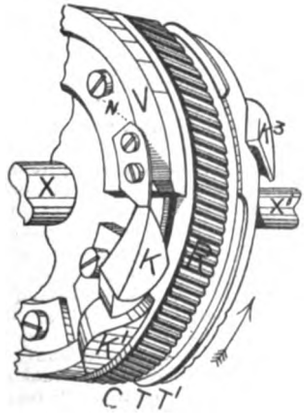

FIG. XLIII.

individual movement to and fro in the direction of the arrow (Fig. XL) but they can only move at right angles to that direction *solidly and as a body*, together forming with C^6 (Fig. XLII) which is *footless*, a solid arc, the centre of which is coincident with that of the combiner wheel C. When no signals are being received the entire arc of selectors remains quiescent, only coming into action when one or more of the selectors are thrown *forward* by the action of their respective appendix levers. In the position of rest the feet of the selectors trail over the periphery of the back disc, or *rest* track T (Fig. XL): see also Figs. XLIII, XLIV. When actuated the thrust of the corresponding appendix lever and its forward movement, guided by the selection disc V, is just sufficient to push the corresponding selector from its position over T to a corresponding one trailing over T^1.

The discs T and T^1 carry a number of slots and blank spaces (see TT^1, Fig. XLIV) which bear the same relationship to one another as do the marking and spacing currents respectively of the Baudot code. For example, the letter P is represented by five consecutive slots on T^1 and five blanks on the disc T, while the letter G is represented by "blank, slot, blank, slot blank" on T^1 and "slot, blank, slot, blank slot" on T. There is naturally only one position on the two discs where this combination can be met,

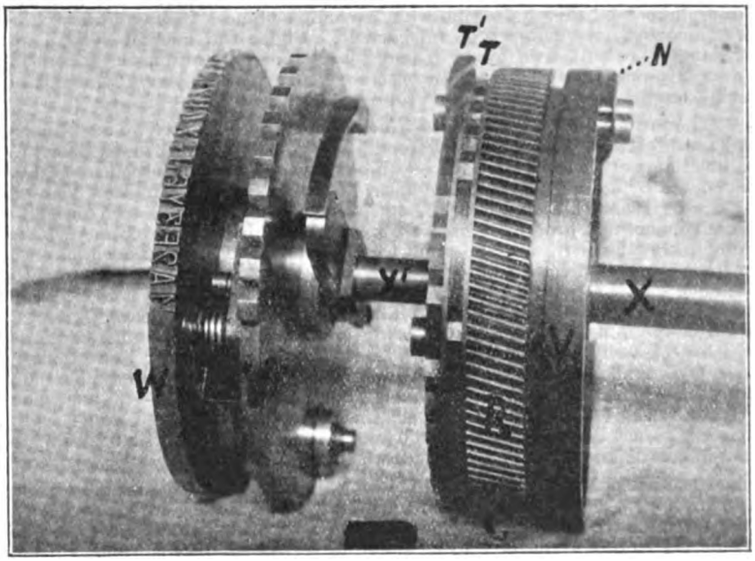

FIG. XLIV.

as also that of any other combination represented by the Baudot alphabet. Thus, when our letter G is signalled, electro-magnets 2 and 4 are energised, their respective appendixes attracted, the appendix levers 2 and 4 are thrust forward, caught up and pressed against the axle ends of selector levers 2 and 4, which are now positioned, 1, 3 and 5, trailing over the disc T, and 2 and 4 over T^1. Gentle pressure derived from a finely-tempered steel spring attached to C^6 (Fig. XLII) presses the five selectors on to the respective peripheries of T and T^1, and the combiner wheel C (Fig. XL), rotating, there arrives a moment when the corresponding combination of slots and blanks on the two discs reaches the five selector feet. As the selectors can only move from right to left as a solid body and not individually, the only movement possible is at that moment when the correct combination is reached. At that moment they drop into their respective places following the electrical permutations of the keyboard at the distant end. This point reached they are immediately jerked out of their respective slots by the rotation of C, which then brings into action a replacing cam K^3 (Fig. XL) which leads the *forward* selectors back from the *working* track T^1 to the *rest* track T by means of a cross-over path provided. All is then ready for the next letter.

* It will have been noticed that the electro-magnets of a Baudot *receiver* are placed in correct numerical sequence and not in the same order of their corresponding keys on the Baudot keyboard, a position necessitated by the evolution from the original Baudot as then designed.

(To be continued.)

THE NAMING OF EXCHANGES.

By P. W. H. MAYCOCK.

THE "automatic atmosphere" which for so long has hung suspended over the ancient and cherished ideals and institutions of the London Telephone Service like the sword of Dam——. Your pardon, Mr. Editor, but the allusion is too hackneyed to complete; and, after all, the breaking-off point may not be deemed inappropriate by those who mourn the passing of the "human touch" in the telephonic art! Let it suffice to say that it has descended. We live—those who are "alive"—on the Calculus—Integral, Differential, Infinitesimal, and—to the non-mathematical mind—Infernal *l* We move in curves, parabolic hyperbolic, and diabolic; and we have our being in a veritable mist of the nightmare formulae by which that most admirable science of mathematics is ever ready to demonstrate, with comfortable assurance and to the sublimated essence of an electron, the value of x— the unknown, and probably the unknowable! On the surface it may seem that this has little to do with the naming of exchanges; but in reality its appropriateness is twofold. It is a mark of up-to-date-ness to begin with a more or less graceful allusion to the automatic atmosphere; while, in its subtle disintegration of the old world of telephony to make way for the new heaven and the new earth of the girl-less millennium of the new telephony, the automatic atmosphere has already begun with exchange names, thus giving a new prominence to the subject of this article. Under the manual system an exchange is identified in terms of language: under the autonatic system in terms of number. It is, therefore, necessary to devise a system which shall make the first readily expressible in terms of the second.

The problem has been solved with characteristic ingenuity by our American brethren. Leaving out the letters Q and Z, the alphabet is divided into eight groups of three letters; and each of these groups, in consecutive order, is denoted by a number, beginning at 2. Thus, A, B, and C are each denoted by 2; the letters D, E, and F by 3, and so on. On the dial of each automatic telephone each group of three letters is shown in close proximity to its numerical equivalent, with the result that the subscriber, who in his innocence imagines he is dialling C-E-N for Central, is in reality transmitting the numerical code 236. It will be readily understood that under this system every exchange in a given area must have a different numerical equivalent. Examination of the numerical equivalents of the present London exchange names—which necessarily have been fixed without regard to automatic limitations—reveals a number of instances in which numerical equivalents are duplicated; and the opening of the first "Panel" automatic exchange—to be called "Blackfriars"—early next year has made it necessary to change eight existing names before the end of the year. Here the automatic atmosphere first makes disintegrating contact with the old order of things.

But this only touches the fringe of the question as it affects London. Of the 67 provisional automatic areas comprised in the development scheme new names have to be found for 38; while the provisional names of the remaining 29 areas will have to be tested in regard to their suitability from the phonetic point of view.

And the limitations of the automatic atmosphere are not the only obstacles that modern development has placed in the way of the selection of exchange names. On the manual side, the automatic atmosphere has its humble counterpart in the Toll atmosphere; which, though it lacks the impressive mystery of its more comprehensive rival, is nevertheless a factor to be reckoned with. The Toll system of working, under which the subscriber passes direct to the local exchange telephonist the name of the distant exchange in the case of calls to the nearer provincial areas, will shortly bring into the daily use of the local system 77 new names. Just as the automatic atmosphere forbids the clashing of numerical equivalents, so the Toll atmosphere forbids the clashing of sounds as between local and Toll exchanges.

Together, the two features of development have converted what was a comparatively simple operation into one of no little difficulty, necessitating a complete revision of the methods formerly employed in the selection of exchange names and the laying down of the framework of a comprehensive procedure susceptible of development in accordance with the more exacting conditions; and since the problem is one likely to confront telephone men in other areas, a short description of the methods now being developed in London may be of general interest.

Under the old conditions, the main criteria of suitability of a given name for use as an exchange name were:—

(*a*). That it should have at least some topographical significance.
(*b*). That it should possess reasonably good phonetic individuality when compared with the names of the other local exchanges of the area.
(*c*). That it should be euphonious, and free from unpleasant associations.

These conditions must still be met, while two others have been added: (*a*) that the new name must possess a numerical equivalent different from that of any other existing or recommended local exchange name, and (*b*) that it should not clash phonetically with the name of any of the 77 Toll exchanges. That the new conditions have greatly restricted the field of selection will be readily understood. It is necessary to state them at some length in order that the reason for the process of elimination described in the following paragraphs may be fully understood.

The first step in the selection of a name is fairly obvious. A map of the area on a scale large enough to show clearly the more important local features is obtained and the actual or probable site of the exchange is marked. Using this as a centre, the map is carefully examined and the names of the principal districts, streets, squares, parks, or other local features are extracted, all names which on the surface appear suitable being included even where an exceptionally promising name is found in the first instance. Experience has shown that transmission tests sometimes reveal defects in names which at first sight would be accepted without question; while in any case the processes of elimination described later make it necessary that the preliminary list should be as long as possible in order to ensure the survival of a sufficient number of alternative names to make a further scrutiny of the map unnecessary. Before the examination of the map is begun, the district superintendent concerned is asked for any suggestions he can make as to a suitable name. On receipt of his report the complete list of provisional names is examined, and any name that may have been chosen already as a provisional name under the automatic development scheme is rejected.

The list is now ready for the second elimination—the removal of names which do not comply with the "numerical code" requirements of the automatic system. The numerical equivalent of each of the provisional names is ascertained, and any name possessing a numerical equivalent identical with that of any existing or recommended name is removed from the list.

The surviving names are now subjected to a third elimination—to meet the requirements of the manual system. Each provisional name is closely scrutinised in relation to all names of existing or recommended local exchanges and also in relation to those of the Toll exchanges already mentioned. Names on the provisional list which on inspection are clearly similar in sound to existing or recommended names are rejected.

The fourth elimination is concerned with the question of phonetic length. Admittedly a matter which permits wide differences of opinion, the standard adopted is that the name should not be of less than two syllables nor more than three. Experience of single-syllable names in London suggests that their number should not be increased, despite the undeniable attraction of brevity. Generally speaking, the more distinctive character of two or three syllable names will more than compensate for their slightly increased time-value in transmission. All single-syllable names on the provisional list, therefore, are excluded if phonetically suitable two or three syllable names have been found.

The list now contains names which, so far as examination apart from actual telephonic use can show, have claims to consideration. Their practical value can now only be determined by experience; and it is at this point that the decisive test is applied. Lists are prepared containing the provisional names distributed among the names of all existing exchanges, other recommended names, and the names of such Toll exchanges as may suggest possibilities of confusion with the provisional names, which are listed in fairly close proximity to those existing or recommended names which they seem most to resemble. Each provisional name appears six times in the list, and all names have arbitrary exchange numbers associated with them. The order in which existing or recommended names appear on the list is varied from time to time; and these names are repeated sufficiently often to permit each of the names under test appearing in six different associations.

Stencilled copies of the list are then sent to each District Superintendent for the transmission tests. The conditions of the test are that all the names on the list should be passed in the order in which they appear by a telephonist at an A position at the "transmitting" exchange and written down as they are received by a "recording" telephonist at the distant exchange working from a service telephone at a supervisor's desk. Before the actual transmission is carried out both "transmitting" and "recording" telephonists make themselves generally familiar with the new names. This is done in order that the tests may be representative of working conditions, under which all exchange names are well within the knowledge of the exchange staff.

The names are passed in this way over three different junction routes of noticeably good, average, and noticeably poor transmission efficiency respectively, the transmitting telephonist passing the names strictly in accordance with standard methods of articulation, taking particular care, however, that while standard methods are fully observed, the new names are not emphasised in a way which would give them undue prominence. On completion of the tests, the list of names compiled by the recording telephonists are forwarded to the transmitting exchange where the new names—as recorded—are underlined in red to facilitate analysis at the Headquarters traffic branch. Transmission tests of each group of provisional names are made in all five traffic districts, the procedure thus ensuring that each provisional name is passed 90 times in circumstances closely approximating to those which would obtain if the names were in common use. Though the number of transmissions may appear somewhat small, the test is made a severe one by the fact that one third of the transmissions are carried out over circuits of noticeably poor transmission efficiency, whereas in actual practice nothing like this proportion of a day's traffic would be handled under such difficult conditions. It is open to argument whether in this respect the test is not too severe, and experience may suggest the desirability of some modification. The test has the advantage that when a name has to be chosen at short notice a severe test can be applied without the expenditure of time and labour involved in the preparation and testing of very long lists of names. The tests taken, the "recorded" lists are assembled at Headquarters for analysis.

Transmission errors fall into two main classes (*a*) cases in which the provisional name is confused with an existing or recommended name, and (*b*) those in which the provisional name is incorrectly recorded but not confused with any other exchange name. Of these two classes of error, the

Digitized by Google

first is the more important, since in ordinary course familiarity with the new name will generally reduce the percentage of error under category (*b*). The final analysis, therefore, is designed to show the percentage of the total transmissions of each class of error and of the two classes combined, in regard to each traffic district and as applied to the group as a whole. In addition, the actual names for which the provisional names had been mistaken are recorded.

Selection of a name is largely determined by the arrangement of the tested names in "order of merit" as measured by total percentage of error. As a rule, names with a percentage in excess of 10 are regarded as unsuitable unless exceptionally free from risk of confusion with existing or recommended names and when examination of the actual names recorded in error shows that they bear such a close phonetic resemblance to the correct provisional name that a telephonist would at once know what was intended directly the provisional name came into common use. Of the names with a percentage of error below 10, that showing the lowest percentage of confusion with existing names is usually chosen. If the difference in this respect is but small, the name with the best topographical significance is selected, so long as its associations are not unpleasing.

Many flashes of unconscious humour illuminate what at first sight appear to be dry-as-dust lists of names. Visions of Christmas must have been passing before the mind of the recording angel who on a recent occasion and in all seriousness wrote down "Mint Street" as "Mincemeat"! Another, with subconscious memories of the kinema, saw "Harbour Lights" in "Marble Arch"; while "Botanic" was variously interpreted as "Mechanic," "Platonic, "Masonic," and "Satanic"! Some of the best-known names have fallen victims to the impish tricks of telephonic speech. Few would recognise in "Ar" and "Tar" the well-known "Tower"; while "Prince" is very effectively disguised as "Frimp"! "Albert" is transformed into "Obutt" and "Kelvin" into "Charles Inn" and "Cows End"! But perhaps the master-stroke of irony was achieved by the genius who recorded "Maryland" —a name proposed for an East End area—as "Fairyland"! Far be it from me to hold up to ridicule the perpetrators of these quaint conceits: they have too often gladdened the hearts of those called upon to do the more or less humdrum spadework inseparable from the preparation of a statistical case. And they can certainly claim to have written one really interesting paragraph in an otherwise dull article!

If no topographical name survives the transmission tests a more or less arbitrary name must be sought. Hitherto efforts in this direction have been restricted to a search for the name of some person, place, or event, prominent in the local history of the district; while the old-world equivalents of modern names may in some cases give names which are phonetically suitable. So far, it has been possible in London to avoid the use of these arbitrary names; but the restrictions of the automatic atmosphere as manifested in its number-code makes this a matter of great and increasing difficulty; and it is already a question of practical importance whether the time has not come for the Post Office to break with its traditions of devotion to the topographical name in favour of arbitrary names drawn from the world of Science or Art—or possibly even of commemorative names of national significance. The advantage of such a system would be that directly the class of men is determined, those names suitable phonetically and numerically can be selected in readiness for immediate use in cases where search for a good topographical name has proved fruitless.

In the space of a short article it is impossible to do more than touch upon a few of the main points of the subject, which is of wider significance than appears at first. To mention one point:—a pleasing exchange name has a marked service value from the development point of view, for not only is such a name a direct inducement to prospective subscribers, but it also goes a long way to minimise the natural objection of subscribers who may be transferred to the exchange from other districts for administrative reasons such as the correction of areas, or the formation of new areas. Much of the public dissatisfaction manifested in connection with the transfer from London Wall to Clerkenwell arose from the fact that the latter name was generally held to refer to a less attractive portion of the City than that denoted by "London Wall." It is in such cases as this, where the territorial name of the area served by a new exchange is not rich in attractive modern associations, that the great value of arbitrary names will be found.

And the exchange name has come to stay. Never while man is mortal will the Central subscriber think of his exchange as "236"; and long after the glow of the last calling lamp has faded, amid a wilderness of whirring cranks, line-finders, and selector will be found lone relics of the Old World of telephony—the exchange names.

THE TELEPHONE AND TELEGRAPH IN AMERICA.

(FROM THE *Saturday Review*).

SIR,—I have read with interest the correspondence with reference to the telephone service in England as compared with that in the United States. The only question discussed appears to be one of power—water or steam; but I think it pertinent to inquire whether the service is really so much worse in England than here.

During the past few years this service has been a standing joke in the American press, and only the other day a man was arrested in New York for unscrewing the mouthpiece and throwing it away, because he could get neither a connection nor a return of the money he had placed in the "slot." Personally, I have been tempted frequently to make some unlawful demonstration of that kind.

Over and over again, when I call up my home, I am told that the line has been discontinued, or "they don't answer," to find subsequently that the room containing my instrument was occupied at the time, but no bell was heard. When I lived in another house, my number was 165, but almost invariably when I called it, I was given 156. The latter was the number of an invalid lady, who was alone most of the day, and had to leave her couch in order to answer when the bell rang. On the other hand, I was frequently called up late in the evening and addressed as Mr. S—— (her brother). I made several complaints to the company, but the annoyance continued until I moved from the house.

Then I had to pay $5 for cancelling my contract, and about as much more for an installation at the new address, although there was a 'phone there which had been used by the previous tenant, and which I adopted. And for each of three months thereafter I regularly received a bill for service at the old address, and just as regularly two weeks later a notice that, if I did not pay at once, the service would be cut off. I received also bills for the new 'phone, and paid.

Such instances form a frequent topic of conversation among my neighbours and business associates, and if you in England can beat us in this connection, then "God help England."

Said neighbours and associates, when they go abroad, tell you that their telephone system is perfect, and write home that England is "a back number."

As to the telegraph service, which is under Government in the British Isles, and carried on by two competing companies here, it was much more satisfactory to the public in Ireland twenty-three years ago than it has ever been here since, and at a fraction of the cost. If you will permit me, I shall give a personal illustration of this also.

Fresh from the sixpenny telegrams and prompt deliveries of Ireland (which was then under British rule), I was awaiting my first "job" in this country; and at 4 o'clock one afternoon I received a telegram telling me to go to New York at once, a distance of ten miles. I had to pay 25c. for the telegram, and immediately hastened to the city, only to find that the message had been handed in at 9 a.m., and the position had been given to another applicant, when I had not appeared by noon. I also found they had prepaid 25c.; so the message cost 50c. (2*s*.), and took seven hours to go ten miles! On complaining, I was told it was nothing out of the usual course, as they had no messengers in the office (a town of 10,000 inhabitants), and had to wait until they saw someone willing to deliver the message at my address, less than five minutes' walk from the office. The extra 25c. was charged for this delivery.

At the present day, if one's name is in the telephone directory he is likely to get a telegram on the day it is sent (if handed in early), for it may be 'phoned to him from the receiving office. Otherwise, his chance is a poor one. I have known several cases of a man, who was more than 100 miles from New York, telegraphing that he would arrive by a certain train, and then reaching home long before the telegram did. And all the trains do not run a mile a minute, by any means.

ENNISKILLEN.

TELEGRAPHIC MEMORABILIA.

"ONE crowded hour of glorious life" was the verdict upon the paper by the Assistant Engineer-in-Chief, A. J. Stubbs, Esq., M.I.C.E., &c., on "Fifty Years of State Telegraphs," read before the Telephone and Telegraph Society on Oct. 18, in the commodious hall of River Plate House, Finsbury Circus. Mr. John Lee, who was absent on official business in Holland, was unable to take the chair, but Sir Andrew Ogilvie, ever ready to help this as every other Post Office institution, kindly filled the vacant seat. Mr. Stubbs held his audience from beginning to end by an uniquely interesting lecture, facilely delivered and punctured with touches of a dry humour which added piquancy to many a point. It was disappointing to find the hall so sparsely occupied, and it is small compensation to know that so many "would have been present had they known of the event." The lecturer's attitude towards the science of telegraphy may be judged by one of his opening sentences in which he described the history of telegraphy as an "entrancing romance.' Here, surely, was no dry-as-dust engineer, a creature of mere figures, equations and calculations, but a real prophet and seer who dared to dream dreams and who read history as the record of man's struggle for knowledge and his triumph in its acquisition. One, too, who realised that the Civil Servant had an honourable occupation in serving the community, and one who also had no doubts regarding the past efficiency of Post Office engineers, joined to abounding confidence in their capacity for even greater achievements in the future. Here and there were little snap-shots of the service rendered to the nation during the war by the engineering department, a glimpse of P.O. ships repairing and laying ocean cables during war-time, feeling and nosing their way into forbiden mine-spread areas so that communication between our island and the continent might be maintained; then a stalwart defence of British telegraph practice, a model for the Empire. As the lecturer proceeded, a comfortable feeling of content passed over the audience as the listeners realised how prominent a part the British Post Office had taken in telegraph and telephone developments. Naturally much interesting matter was compulsorily omitted, a fact which the audience tacitly admitted. It is not every scientific or historic lecture delivered that may be listened to for over one hour and yet leave its listeners, not only untired, but even asking for more.

The number of Telegraph Money Orders from India to this country during the month of October was abnormal, running easily into a value of six figures measured in pounds cash. According to a regulation laid down by the Indian Government only a very limited number of these telegrams is permitted during a specified period. This was apparently designed to render the transmission of abnormal sums by the telegraphic medium inconvenient and finally impossible. The object of the restriction during the present sensitive condition of international exchange is obvious. "However, where there's a will there's a way" and as there is no regulation controlling the number of TMO's *to* a person although, as already stated, there is a strict limit to the number and total amount that may be transmitted by any one sender, a very easy loop-hole appears to have been found, by means of which the regulation has been rendered nugatory. The simple method adopted is that of a multitude of senders to a comparatively few receivers with the result that a veritable procession of Hindu names with varying prefixes and suffixes and permutations of the same has streamed across the cables, even the names of some of the Hindu gods and goddesses being utilised for the purpose!

In direct connexion with these features of the Anglo-Indian Telegraph Money Order business the following excerpt from the most recent Annual Report on The Posts and Telegraphs of India, 1918-1919, should prove interesting:—"The total number of telegrams exchanged between India and Ceylon was 309,566, an increase of 22 per cent. over the preceding year. This large increase is due to a rise in the *telegraphic money order traffic* and to frequent fluctuations in trade." It may also be added for the information of the general reader that Ceylon has its own currency quite apart from India, which may also account for some portion of the increase, as the factor of "rate of exchange" thus becomes a far from negligible quantity even between these two colonies, geographically so close in proximity, yet governed respectively by two different British departments, *i.e.*, the Colonial and India offices. For the same period the increase of this same type of traffic between the United Kingdom and India closely approximated to 100 per cent.

This same report, by the way, reminds one of the curious functions at times and in certain places, which are performed by Government Post Offices, a special paragraph being devoted to the item that, "The Post Office obtained 11,844 lbs. of quinine for sale to the public during the year." This is surely related to *The Red Milkman* by Mr. John Lee!

I am indebted to a correspondent for raising the point as to who was actually the originator of the electric telegraph. Elsewhere it has been stated that Charles Morrison, a surgeon, and native of Renfrew, has been recognised by the chief electrical authorities as the originator of the idea of transmitting electrical signals by wires carried above ground on poles and insulated by glass supports. The method this foreseeing scientist proposed was set forth in an article signed C. M. in the February number of *Scots' Magazine*, 1753, which suggested erecting 26 wires, and providing each with a suspended pithball at its end, the energy to be derived from frictional electricity, each pithball to represent a certain letter of the alphabet. The identity of Charles Morrison with C. M. of the above article appears to have been well established and to have been fully recognised by all the electrical and scientific authorities, including, I believe, the Royal Institution. Unfortunately, the burning down of Renfrew town hall somewhere about 1880 destroyed all local records, but sufficient evidence apparently remained to enable investigators to establish the claim of Renfrew's citizen, as a plaque may be seen in the Science Museum of South Kensington, designed and cast to signalise and to fix the honour upon Morrison. Other brains were at work along similar lines, notably Sommering, whose method employed the release of hydrogen bubbles in inverted test tubes fixed at the end of each individual wire, but to Morrison belongs the inception of *over*head insulated conductors as to Ronald belongs the idea of *under*ground insulated lines. Specimens of the actual wire and the glass tubing used by the latter in his garden at Highbury may also be seen in the same museum. An additional point of interest also attaches to the information that an inscription may be seen engraved on a stone at Kelmscott House, Hammersmith, where William Morris, the poet, formerly lived, which reads as follows:—

> "The first electric telegraph 8 miles long was constructed here in 1816 by Sir Francis Ronald, F.R.S."

By an unfortunate accident, no reference has yet appeared to the fixtures of the C.T.O. Football Club (Centels F.C.). It is not, however, too late to repair the omission, and one notes with keen satisfaction that an excellent Thursday programme is fixed practically up to March 24. This programme includes several contests with police divisions. Let me hasten to explain that the latter are in the purest sense of the word "*friendly*" matches! These signs of gradual return to normal conditions are doubly welcome and the reflex will doubtless be felt in renewed health and a shorter absentee list.

I wonder if the following little comment may be permitted on one's experience of the telephone? It is no criticism on the promptitude of staff or the working of apparatus, but quite recently I happened to be in a seaside town, the resident population of which runs into several thousands. In the main road was situated, as was fit and right, the Post and Telegraph Office, ably served. Enter a lady. "I want to 'phone, please?" was the simple request, to be met with a courteous expression of regret that there was no 'phone laid on, but that by walking further down the road, crossing the railway bridge and descending about 20 steps the applicant could obtain a trunk or local call at ——, the tobacconist! The applicant was a *real* lady for she only said, "Oh, dear!"

The promotion of Mr. Thomas, of the Controller's Office, C.T.O., to the sub-postmastership of March, may not be permitted to pass without the sincerest expressions of regret at his departure which have been voiced by his many many friends. The March Post Office is indeed fortunate in having for its new head one who is so fully entitled to the appellation—in its purest and best sense, of gentleman.

On Oct. 9 there also quitted the C.T.O. in the person of Mr. J. Fisk, yet another of the most respected of superintendents, one who has a long record of good work performed, and of many an association with T.S. activities, having been a member of one of the first volunteer companies, which preceded even the old 24th, and, to mention but one other link, was prominently associated with the Dining Club. It was evident to all that when the actual moment came for stepping out of the office for the last time as an official, the wrench was a very real one to our much-esteemed friend and colleague. This in itself is no mean tribute to one who has spent over four decades in the Service.

Trials with Siemens' high-speed apparatus between London and Berlin are in progress as this goes to press and have reached an interesting stage.

It is hoped that direct telegraphic communication between London and Prag will, ere long, become an established fact. The re-opening of the London-Vienna wires is also spoken of as a coming event of the near future; as also, but probably at a more distant though not remote date, that between Budapest and the British capital. Thus gradually the healing effect of telegraphy is being felt throughout Europe. Much, very much, remains to be done before a much-to-be de-ired stability is reached in regard to many of the continental lines, for these have not apparently been left immune from the wearing effects of the recent general upheaval. The glimmers of hope of re-construction which some of us have seen during the darkest hours are steadily gathering force. Not the least of these is the increasing number of recruits for the Foreign and Colonial section of the C.T.O.

It is more than gratifying to place on record the success which has met the appeal for a collection on behalf of the Benenden Recreations Fund. Will all readers please note that this is a Post Office Fund without restriction, and should have the active sympathy of every section of the Service.

Miss Hall and Miss Lloyd are both leaving the C.T.O. for the Ministry of Labour. They leave us with the heartiest possible good wishes from their colleagues of both sexes in the Cable Room and elsewhere. Mr. E. Annible also quits the Cable Room test box duties for a wider sphere of usefulness at the North Walsham Repeater office. He leaves a gap not easily filled on the technical side, and on the social side he will understand our united acclaim of, *Vive le roi*!

J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

THE holiday period is over now and the staff in the district are settling down to a strenuous winter campaign. Fortunately, the summer has been a particularly cool one and so no excuse for slackness, due to the enervating effect of the sun beating down through clear skies on a large and densely populated town, can be made. No doubt the weather which proved disappointing to holiday makers was beneficial in preventing more breakdowns amongst a staff struggling valiantly with reconstruction problems. At

Digitized by Google

the time of writing there are signs of improvement in the matter of supplies and stores, and there are hopes that the time is approaching when engineers will have sufficient straw or its modern equivalent with which to make bricks, and that it can no longer be said that the road to Hell is paved with stores requisitions.

* * * *

Post Office Telegraph and Telephone Society.—The Post Office Telegraph and Telephone Society opened the Session on Monday, Oct. 18, with an address fron the President, Mr. A. J. Stubbs, Assistant Engineer-in-Chief. No doubt the address will be printed in this JOURNAL in due course. It was of entrancing interest and was enjoyed thoroughly by those fortunate enough to be present. Mr. Stubbs traced the development of the art of telegraphy in this country from its commencement to the time when it was ruled that a telephone was a telegraph within the meaning of the Act, and so on, to the present time. Many names of men who had done outstanding work in connexion with the development of the art were quoted and it is interesting to note that several of our present-day colleagues were included in the roll of honour. Mr. Stubbs spoke very highly of the important part taken by the Department's engineers in the progress of telegraphy and telephone, and no one is in a position to speak with greater authority on this subject than he. Reference was of course made to the work of the P.O. staff during the War, and a hope was expressed that some day a complete record of such work would be given to the world. No doubt the audience would have been much bigger had individual notices to members been circulated instead of their attention being drawn to the meeting only by means of diminutive posters. This opportunity is taken of drawing the attention of members of the London Engineering District to the excellent series of lectures given during the winter months by this society. Those who can appreciate a varied programme of papers dealing with all phases of the department's work, followed by discussions in which the views of members of all branches of the Post Office are heard, should make a point of attending. The December meeting will be held on Monday, Dec. 13, when Mr. F. C. Cook will read a paper on "Studies in Whitleyism."

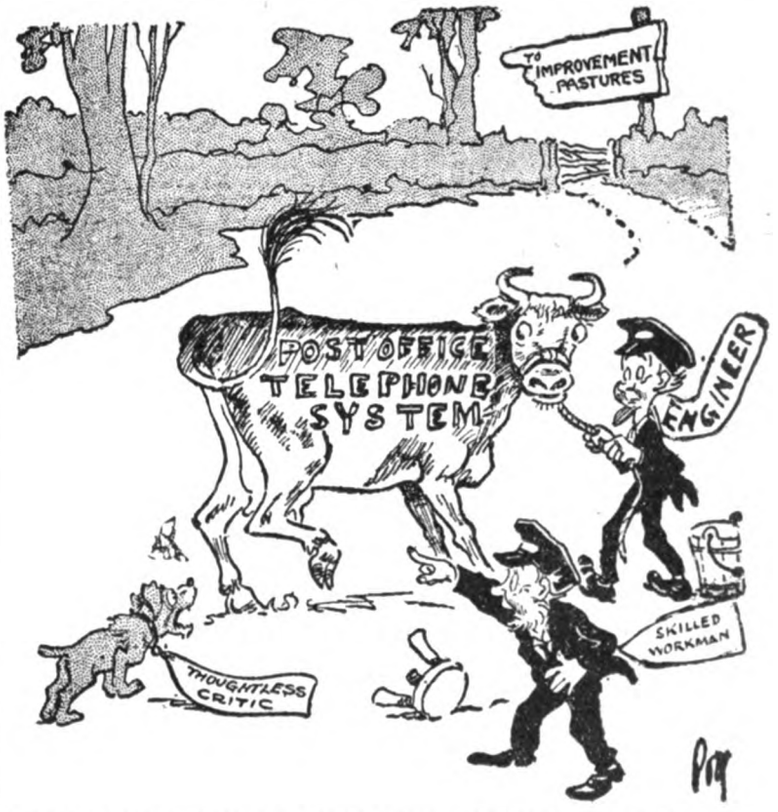
Institution Meeting.—The Institution of Post Office Electrical Engineers held its second meeting this Session on Nov. 8, when Mr. G. F. O'dell, of the Engineer-in-Chief's Office, gave an address on "The Influence of Traffic on Automatic Design." The tightly-packed hall testified to the interest taken in anything connected with automatic telephony. Amongst the visitors were representatives from the various manufacturers of telephone plant and many of our colleagues of the Traffic Branch.

Mr. O'dell dealt principally with the methods of determining the number of selector switches required in the various stages of a call, and explained how the correct number could be arrived at with the aid of the theory of probabilities, the employment of artificial traffic investigations and also by actual traffic records.

Considerable attention was given to the important question of the grade of service which should be given to subscribers. The importance of the flexibility of plant to enable variations due to traffic changes to be made readily was emphasised. The human operator may have her faults, but she is able to do something that the machine cannot do, that is, to meet rushes of traffic by spurts of energy. The need of plant flexibility has been abundantly demonstrated in recent years. There are at present very considerable differences between the equipped and traffic capacities of exchanges in connexion with which there is no line plant restriction. These differences are doubtless brought about by changes which are beyond control and unforeseeable, but they do indicate what should be sought for in future systems.

The address was illustrated by a number of slides, showing curves based on theoretical and experimental data.

The discussion which followed was opened by Mr. John Lee of the C.T.O. It was unfortunate that the length of some of the speakers' remarks prevented several would-be speakers being heard.



Cable Breakdown.—The bursting of a high-pressure water main in Oxford Street recently caused considerable damage to the department's plant, some 890 circuits being affected. The trouble was located to a manhole which contained a cable head and some multiple joints. After all the water had been removed from the manhole, the conductors of the cables were examined and it was found that water had penetrated the cable distribution head and the mutiple joints. The insulating paper was very wet. A number of torch blowing lamps, three motor desiccators and the Museum Exchange desiccator were at once brought into use to prevent the damage spreading, and to dry out the cables. A number of the wires affected carried junction circuits, and these were quickly diverted to other routes so far as spare circuits were available. About 30 faults were cleared by the evening of the 7th, and by midday on the 9th practically all the circuits were again working. The water had penetrated so far into one of the cables that it was necessary to renew the whole length of 144 yards. It was noticed that electrolytic action had taken place in all the cables affected. The inconvenience to the subscribers is to be regretted, but there is no doubt that but for the prompt and suitable measures taken by the Sectional Engineer and his assistants, the damage would have been considerably greater.

Church Parade.—The Post Office Division of the Metropolitan Special Constabulary Reserve paraded on Sunday, Oct. 31, for Divine Service at Westminster Abbey. The Division mustered on the Horse Guards Parade and was played to and from the Abbey by the Band of the "A" Division Metropolitan Police. About 300 officers and men were present. Of these 8 officers, 54 sergeants and men were drawn from the staff of the London Engineering District.

Denman Chess Club.—The first match of the season was played on the 3rd inst., against the London Telephone Service and resulted in a win for Denman by 7½ to 2½ games. Full score :—

Board No.	DENMAN.		L.T.S.	
1	Mr. Cornwell ...	½	Capt. Rathbone ...	½
2	„ Slattery ...	1	Mr. Coburn	0
3	„ Barrett ...	1	„ Larkins	0
4	„ Wenman ...	0	„ Bostock	1
5	„ Francis ...	1	„ Hinshilwood ...	0
6	„ Gardiner ...	0	„ Kirchoff ...	1
7	„ Eastop ...	1	„ Gray	0
8	„ Petchley ...	1	„ Wiles	0
9	„ Freeman ...	1	„ Haugh	0
10	„ Nevill ...	1	„ Gregory	0

A Nasty Shock.—The engineer responsible for the well-being of the exchanges south of the Thames suffered a shock the other night. Someone rang him up shortly after midnight and announced the startling news that one of his exchanges was ablaze. Naturally somewhat perturbed, he asked his informant for particulars and he was told that the *sixth* floor was well alight. Then, of course, it came out that the Hop Exchange was concerned, which, as our readers may know, is an imposing building in Southwark Street devoted to the merchandising of the fragrant hop, and not the Hop Telephone Exchange, which is a quarter of a mile away. Much relieved he went back to bed.

STOP WORRYING THE BEAST ! WE ARE GETTING HER THERE AS FAST AS WE CAN.

(Adapted with grateful acknowledgments from a drawing by "Poy" in the *Evening News.*)

A New Word.— A newspaper with a tremendous circulation and a penchant for attacking the telephone system, in reporting Sir William Noble's opening address before the Institution of Post Office Electrical Engineers, gave him as referring to the "*Officiency* of the telephone service in the United States." We do not think he used this particular word, but nevertheless we offer it to our readers as a really good portmanteau word expressive of official efficiency, and we say it with due modesty—well applicable to ourselves.

The following letter received by one of the engineers in pre-transfer days will be read with interest. Coming events apparently were strong enough in June, 1911, to leave some doubt in the writer's mind as to the identity of the company whose clerk he was interviewing, hence the term "National Telephone Service Post Office Company." In the midst of references to "gramaphones" chemical wires, "X-rays" and shocks electric, it is not easy at first to see that the complaint is against the humming noise caused by

Digitized by Google

overhead wires near the house. It would be interesting to know whether the company's engineer managed to satisfy the complainant:—

11, HEREFORD ROAD,
BAYSWATER, W.
June 9, 1911.

SIR,

To-day I had a clerk from the National Telephone Service Post Office Company in answer to my letter with reference to these wires which are across my street and over my head. He assured me all their wires were underground so that I could not hear noises. He said these were National Gramaphone wires over me. Now I beg to state that I have *no such* in my premises as Gramaphoners. I, therefore, beg you will at once remove any such wires which are annoying me *night* and *day*. If they be these chemical wires to *indicate* where X-rays is kept, if it is Mr. Butterfield's premises you must remove them. I will not allow myself *affected* by any such wires. I am so severely shocked at times *electric*. Causing me great pain. I must now *insist* and *command* any such wires at once removed from hovering in, or on or round about my premises. I have no such employers as *servants*. I believe the annoyances to be coming from Westmoreland Road, a man by the name of *Crocksford & Co.* I have received so much annoyance from same parties. I will now take proceedings against them and their wires. If they have anything to do with Otto House or any such houses, I beg to state *they* have nothing to do with me from *any* such houses. Kindly send and remove these wires at once. I am not a *trader* neither is my landlord. Causing me so much annoyances. The sounds are Gramaphones talking also of *Ajax drums* in either of these I am not a dealer or an hirer so apply to you and give you my *orders* to remove any wires that are so annoying me.—Yours truly,

R. H. N.

Some little while back, reference was made in these notes to hobbies. It may be of interest to some to know that the illustrations accompanying the articles on the London Engineering Department are from photographs taken by an amateur photographer on the Denman Street Clerical Staff, Mr. J. E. T. S. Hilton, who will be pleased to provide copies at a very small charge.

Recently the authorities responsible for the underground railways of London issued in the daily press a manifesto explaining their difficulties and printed the moral with sketches by "Poy." We suggest that the difficulties that beset the Post Office in their efforts to overcome arrears due to the War are far greater than those experienced by the Underground Railway Co. Perhaps the P.M.G. will consider the advisability of also issuing a manifesto. One of Poy's cartoons slightly modified as above will serve to illustrate it.

REVIEWS.

"*The Civil Servant and His Profession.*" *Sir Isaac Pitman & Sons, Ltd.*, 3*s.* 6*d. nett.*—We have no hesitation in recommending this book to those of our readers who were unable to attend the series of lectures delivered to the Society of Civil Servants in March, 1920. Those lectures are here reproduced in handy book form and we here find Sir Cecil Harcourt Smith, the late Sir Robert Morant, Lord Haldane, Sir Sidney F. Harmer, Mr. E. F. Wise and Mr. John Lee at their very best. All civil servants should peruse these testimonies to the wide scope of their profession if, as Sir Cecil Harcourt Smith says, they are to possess that "guid conceit of ourselves" which is only another expression for self-respect.

"*Vocabulaire en Cinq Langues avec répertoire alphabétique.*" Par Henri Viard. Gauthier-Villars et Cie, Paris. 108 pp. Price 7 francs 50 with temporary increase of 100%.—This is a very useful and up-to-date vocabulary of expressions used in wireless telephony and telegraphy in five languages. The appendix sets out the American and International Morse codes and contains some useful mnemonic hints with regard to them; also in five languages, viz., English, French, German, Italian and Spanish.

WE acknowledge with thanks from colleagues in Stockholm Nos. 40 and 41 of the Swedish journal,, *Svensk Trafiktidning.*

RETIREMENT OF MR. F. COWLEY.

On the occasion of the retirement, in August last, of Mr. F. COWLEY, Telephone Superintendent for Ireland, it was decided by a number of his colleagues of the late National Telephone Company, Limited, and the staffs of the Irish Districts (Dublin, Belfast and Cork) to present him with some token of their esteem. Considerable regret was felt that, on account of Mr. Cowley's ill-health, which necessitated his absence from Ireland, it was not possible to arrange a formal presentation in Dublin to convey to him the best wishes of his colleagues and the Telephone staff. A pair of field glasses and a silver urn were, therefore, forwarded to him, and he expressed a wish that his best thanks be conveyed through the medium of these columns to those who participated in the gift.

THE TELEPHONE AND TELEGRAPH SITUATION IN GERMANY.

BY W. H. GUNSTON.

ACCORDING to Dr. Bredow, of the German Postal Administration, the telegraph and telephone systems of that country are in a critical condition. There is a deficit for the current year amounting to two milliard marks, whilst before the war there was always a handsome surplus. With the constant rise in the price of materials and salaries it has been found impossible to make these services pay their way. Wages are six to eight times as high as formerly; the price of iron wire has risen by more than 3,000 per cent., of copper wire by 1,200 per cent., of underground cable 2,000 per cent., of telephone apparatus by 2,000 to 3,000 per cent. Traffic has increased heavily since the war, and repairs and extensions necessary (the latter involving 1,000,000 kilometres of wire), will entail an expenditure which cannot possibly be covered by revenue.

The Government is, therefore, faced with the choice of maintaining the services on the present basis at the expense of the taxpayers and at a huge loss, or of placing them on an independent basis and raising them to their former level of efficiency. The charges for telephone service have been twice doubled since 1914, but as the cost of erection and maintainance of plant has increased about twelve and ten times respectively a great disparily has existed for several years between the benefits enjoyed by telephone users and the expenses of the administration. To bring these two into accord, a telephone tariff based on industrial and economic principles is being introduced. The flat rate will be abolished, as it is injurious both industrially and technically, giving preference to persons making constant use of the telephone at the expense of those using it less frequently. It may be recalled that in 1907, the Postal Administration projected new tariffs involving the withdrawal of the flat rate, but the introduction of these tariffs was postponed owing to the protests of larger users, and they were never put into effect.

Dr. Bredow states, according to the *Berliner Tageblatt*, that dissatisfaction had been caused by the proposed new regulations. The protests were, in his opinion, entirely unjustifiable. The existing tariff was unpractical and would be done away with, but the new rates would by no means correspond with the depreciated value of money and rise in prices. Referring to the forced telephone loan—a charge of 1,000 marks payable on main lines and 200 marks on extensions—he said that this was an action which called for gratitude on the part of the public, as without it the entire system must inevitably have collapsed. The sum of money thus obtained might in case of necessity prove sufficient to place the system on some sort of working basis, but further funds would be required if the urgently-needed extensions were to be carried out. Since the introduction of a higher tariff, 123,000 notices of cessation had been received. On the other hand, 111,000 new applications had been obtained.

The new tariff was designed to place the service on a sound financial basis. It was thought that at no distant date the deficit would disappear, and, given political stability and the whole-hearted support of both officials and employees, a reduction in rates might then be possible. The re-establishment of the telephone service was in full swing and appreciable improvements had been introduced. Construction work under existing conditions, however, advanced slowly and it must be years before the German telephone system reaches its former level of efficiency.

It may be added that the number of telephone stations in Germany has increase from 1,421,000 before the war to 1,767,156 despite the loss of Alsace-Lorraine, the Polish provinces and other territory. Berlin has now 187,892 stations, Hamburg 80,697, Munich 41,504, Leipzig 37,732, Frankfort 35,003, Cologne 33,764 and altogether 21 towns have a total of over 10,000 stations.

EDUCATING THE PERVERSE PER VERSE.

WE understand that the London Telephone Service had under consideration a scheme for furthering the education of telephone subscribers on the mnemonic principle by means of short rhymed instructions which we presume would have taken the place of those headlines in the *Telephone Directory* which evoke so much comment in the Press. The scheme was not adopted, but we have received from an anonymous correspondent who seems to be in touch with "the other side," the following efforts in the same direction by well known hands.

Loath'y 'phone, or e'er my fingers
  Wake thy distant lantern's slumber
Let me see if still there lingers
  Recollection of her number.
Yes, I know, the fray's beginning;
Guard, O Gods, my tongue from sinning.

Maiden stern, thy query cheating
  Re the number of her circuit
Was not lost by my entreating,
  Yet it doesn't seem to work it.
Nearer still my lips I get—so—
And my voice I make more mezzo.

Clearly now I breathe the digits,
  Prefaced by the name of Hesper*:
Shortly I shall get the fidgets:
  Soon I hear a strange voice "yes" purr.
Oh, the devil: fives and nines
Sound the same upon the lines.

Firmly, through my craning neck, "O"
  Mouthing like a broad Omega
Hear I yet no answering echo:
  What's the matter with the beggar?
Ah, I listen, listen vainly:
Yet I may not speak profanely.

Often must I firmly say "No"
  'Ere I hear her speak her name.
I believe, *salis cum grano*,
  Now she's got it, all the same.
Yes, we speak, and soon the throbbing
"Vale" o'er the wire is sobbing.

All is over: Fasten rigid
  The receiver in its socket.
The monition leaves me frigid:
  Suffer me awhile to mock it.
  None shall ring me, if I know it,
Till I've shed my rôle of poet.

R****T B******G.

* *Sane intelligendum est* "Western Exchange."

Out of the P.B.X., where pendulous
The cords drop idly and the maidens knit
And fitters that do everything but fit
Maintain the lines removed from haste or fuss,
Haply there comes a call: thou, turning thus
Unto the orifice thy lips admit
And breathe into the darkling heart of it.
The name whereof thy soul is amorous.

Yea, breathe thy name and hearken to his own,
Thy friends, and interchange in emulous tone
The words that bid him buy or bid thee sell:
And when thy soul is sated with the 'phone
Let memory bid thee teach the wire to moan
With the last wind of passionate farewell.

D. G. R*****I.

"A TYPICAL CALL."

TENNYSONIAN FRAGMENT.

I sat in anguish at the telephone,
Within my ear the intermittent buzz
And the receiver in my languid* grasp.
For forty-seven minutes by the clock
I with my broker laboured to hold speech
Anent the purchase of some rubber shares,
And thirteen times the angry resonant wire
At regular intervals reverberant
Had stated that his number was engaged
While seven times I held sweet intercourse
Not with my broker, but some other wight.
With bitter close-compressed lips I cursed
The Gods, the P.M.G. and the Exchange,
When thro' the inspissated gloom there flashed
The image of a face once seen by me
At a suburban hop, and introduced
As Supervisor on the Dud Exchange,
Wherein my line through mazes intricate
And convolutions of the copper loop
Connected with a jerk and found repose.
Then, as in some dark dungeon after pain
And torture, when the door on grating hinge
Back-flung recoils and floods the cell with light
And radiance, and the strong deliverer's cry
So sat I chortling, and my tears were dried,
Nor more than fifteen minutes yet elapsed
'Ere I had held sweet converse with my friend
—It ended on his side with one swift word
The wire transmitted shuddering as in grief.
But that I recked not—I had bought the shares
And in a rising market; and I rose
And blessed the goddess of the permanent glow
Urania, Polyhymnia, or as Form
One Forty-one prosaically states,
Assistant Supervisor, Bessie Jones.

*This was wrong: "grasp the receiver *firmly*."

SOUL TELEPHONES.

INFORMATION has been received from New York that Mr. Edison is perfecting a machine to enable mortals to communicate with the spirit world by telephone.

According to the *American Magazine* for October he firmly believes his invention will establish communication with the souls of the departed by "purely scientific means." Undoubtedly this is extremely interesting from a scientist's point of view. Mr. Edison's explanation of his delicate instrument is fascinating in theory but hardly practicable.

Assuming that the inhabitants of the spirit world are able to ring up when they fancy any harrassed beings still toiling along on this earth, who will be responsible for the payment of these calls? Telephone operators, like other mortals, work for money—not love—and somebody will have to pay, as this traffic between the living and dead, if established, bids fair to become enormous. The only way out of the wood will be to reverse the present order of procedure and send the accounts to the person called. This will be double torture to some poor mortals if undesirable friends or relatives keep up a bombardment of messages from the "other side."

Wrong numbers will become a complicated problem, and it is to be feared that even Mr. Edison will be unable to avoid these lapses.

Certain advantages would be obtained. For instance, no murderer could escape justice, owing to the victim being able to give information first-hand by telephone.

With all due respect to Mr. Edison's genius let us hope he fails, as the disasters likely to arise from such an innovation are unlimited and far outweigh its benefits.

R. A. R.

THE POST OFFICE TELEPHONE AND TELEGRAPH SOCIETY OF LONDON.

The revised programme for the remaining papers before this Society is as follows:—

1920.
Dec. 13. Monday.—"Scientific Management," by Mr. John Lee (Controller, Central Telegraph Office).

1921.
Jan. 17. Monday.—"Wireless Communications," by Lt.-Col. C. G. C. Crawley, R.M.A. (Deputy-Inspector of Wireless).

Feb. 21. Monday.—"Studies in Whitleyism," by Mr. F. C. Cook (Accountant General's Dept.).

Mar. 21. Monday.—"Imperial Telegraphic Communications," by Messrs. A. Avery and H. A. Betteridge (Central Telegraph Office).

April 18. Monday.—"Some features of the American Telephone System," by Mr. R. P. Crum (Traffic Section, Secretary's Office).

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. DECEMBER, 1920. No. 69.

AUTOMATICS FOR LONDON.

THE *London Telephone Directory* grows and grows. It has become almost the standard work of reference for those who are in search of the addresses of particular persons. We shall hear later on something of the methods by which this vast volume is brought up to date and issued. At the moment it is enough to recognise in it the tangible expression of the growth of the London Telephone area. If Bismarck said of London "What a place to loot!" the enthusiastic admirer of automatic telephones may say of it, "What a place to reconstruct!" Mr. Pink, in his paper before the London Telegraph and Telephone Society, gave us a vision of what it entails. There were no purple patches in his paper and no need for purple patches. He held his audience breathless by a careful and precise and detailed statement of the new Blackfriars Exchange and of the complex arrangements which have to be made to fit that exchange in with the vast manual system of London. The new exchange is to be "Panel" automatic. Later on we shall publish Mr. Pink's paper in full and we leave the details of the traffic arrangement to his admirable exposition. At the moment we are concerned only with the arrangements which he explains for fitting in this new automatic with manual plant on a large scale.

The dial has a new development. In addition to the digits there are allotments of twenty-four letters of the alphabet, three to each of eight digits. It takes seven motions of the dial to discover a London subscriber, and of these seven motions three are letters and four are figures. The three identifying letters are to be printed in an indicative way in the directory, thus—"HOLborn" and the Holborn subscriber 2631 will thus become "HOL 2631." If there are less than four digits in the number, preliminary ciphers are to be introduced. Thus the earlier motions of the plant will grope their way through the maze of junctions to the appropriate exchange. There are devices for re-directing—admirable Post Office word—the process; there are arrangements for searching other lines when all the normal lines are engaged; there are arrangements on each manual board for flashing up the required number (for the cleverest of automatic plants cannot whisper to the "B" operator); there are even more subtle devices at chosen centres for flashing all the seven indications, three of them to indicate the exchange and to be translated into letters; there are "tandem" exchanges for through automatic working, and there are automatic registers and methods of storing the signals which open up an amazing vista of the conquest of complications. When the New Zealander sits upon the ruins of St. Paul's he will be able to meditate upon a telephone organism the full detail of which profoundly impressed us in the long by-gone year 1920.

Where there is no vision the telephone traffic expert perisheth. Mr. Pink had his historic moment. In calm and restrained language he showed us what is bound to come to pass, alas, long after most of us have succeeded in calculating accurately the amount of bonus due to us at the sad moment of pension. Here is an opportunity for study and research which fulfils the needs of the hungriest. There is the allotment of junctions under this scheme and the provision of alternative routes, the increase in complications on the residual manual boards when more and more automatic exchanges have been included in the congeries, the increased complexity of the junction centres and of the tandem switching centres, the concentration for a night service which will go along sweetly by itself and of a Sunday service of week-day quality which will not offend the susceptibilities even of a suburban churchwarden. Speakers followed Mr. Pink, one and all oppressed by the real solemnity of the occasion. For it was an epoch-making moment, nad Mr. Lee's flicker of mere cheerfulness was in vain. Those who come after us may look up the files of this JOURNAL, if they wish, and see how we regarded this momentous initiation into the mysteries of the London telephony of the future. We pass to them this heritage. We have lived our day, and in season and out of season have striven to give the public—and have not striven in vain—a thoroughly sound service which is more worthy of comparison with other telephone services in the world than some people suppose. They have the silent machines where we had the telephonists as loyal comrades; they have all the aids for indicating faults and deficiencies—if there are faults and deficiences in that halcyon day—which ingenious science can provide. They have opportunities for study and research and timely provision which surpass our opportunities. We bid them go forward and live up to their advantages.

BRAIN WAVES.

Do we not sometimes overlook the all-important fact that however intricate and wonderful a machine may be, it still is but a machine and lacks a brain to direct an action or to conceive the moment's need? To our relief, indeed, its study does not carry us into the uncertain but much-trodden paths of psychology, despite

Digitized by Google

the fact that poetic imagination has from time immemorial endowed ships and other inanimate objects with souls.

If, however, we pause but a minute for reflection we realise that human intelligence is a necessary part even of the simplest jobs. The unguided vacuum-cleaner could not discriminate, and our diamond studs or ear-rings—if any—might perchance vanish instead of yesterday's crumbs and cobwebs. The motor without a driver would run amok or turn towards open fields and pastures new, leaving us without the week's washing. And a skipperless boat would drift hither and thither at the caprice of every tide and puff of wind, with much loss to the food profiteers.

There is the same need for intelligent control in telegraphy and telephony. Without it, telegraphy would indeed become what a journalist has described as mere "dashed dottiness." In telephony, automatic exchanges are the last word in machine switching; but the control is only shifted from the exchange to the subscriber. He must select the right number, and transmit his demand correctly in the pre-arranged way to the machine, guiding its actions until his line is connected with that of the person he wants. If he has selected the wrong number or misguided the machine, there is no operator to blame and his only remedy, according to a well-known Postmaster, is "to kick himself as a silly ass." The connexions completed, the conversation pursues its normal course and at the direction of the subscriber, the machine releases both lines. If every telephone was directly connected with the public exchange and its number easily found in the directory, the subscriber's control would meet all needs; but the telephone service serves not only the man with one telephone, but also him that hath many. And the bigger the subscriber's business, the more complex his telephone system and the more urgent the need for an experienced brain to direct his incoming calls to the proper unit. We know how impossible it would be for a customer in person to select for himself the department of a universal provider in which he will find the particular gadget he wants. How much more difficult would it be for him to find his goal if the only help were a list of telephone numbers with a necessarily abbreviated classification? The desire would most surely go before the coveted article left the emporium. In all automatic private branch exchanges, it is therefore necessary, because of the need of guidance, to provide manual equipment to deal with incoming traffic, and the result has many advantages. The Post Office saves 90 per cent. of the underground wires needed for direct lines, the Stores increases its sales and the customers are satisfied. The only person who has any cause for dissatisfaction is the writer of anonymous paragraphs who periodically proclaims "The Doom of the 'Hello Girl.'" And who cares a jot for him and his brain waves?

HIC ET UBIQUE.

NEW telephone tariffs were introduced in Sweden in October last under which the subscription in Stockholm has been increased to £16 10*s*. including 5,000 calls, £23 2*s*. including 8,000 calls, and £27 10*s*. including 10,000 calls. We learn from the *Financier* that those increases have aroused a storm of indignation all over the country and that almost every day there are reports in the papers of meetings and petitions to the Administration from chambers of commerce and other public bodies on the subject. Before the Allmänna Company was acquired by the State competition kept the rates at an unremunerative figure, but the Stockholm subscriber doubtless looks back with regret to the old uneconomic charge of £4 10*s*. and thereabouts for which he obtained service in 1914.

AN echo of the Greenwood case. Carmarthen Post Office during the trial broke all local records in regard to telegraphic matter. Thirteen extra telegraphists were drafted into the town from Swansea, and the staff has dealt with an average of 70,000 words daily of Press matter alone.

The telephones, too, were busy all day, and the reports were received in London almost as quickly as if the trial had taken place there. In fact, the verdict reached the capital within three minutes of its announcement in Carmarthen.

AFTER a lecture given by Mr. Sidney Webb on Friday, Nov. 12, on "The Administration of Industry" in the "Coming Commonwealth," the following question was put to Mr. Webb:—"How is it, if Nationalisation can do so much for industry, that a large concern like the Telephone Service is now twice as costly and only half as efficient as when it was under commercial control?" Mr. Webb, after repeating the question, said his reply to the questioner must be a complete negation. The Service, as witnessed by the general opinion of users, is *not* inferior to that rendered by the late Company, and if the enquirer would take the trouble to examine the back files of *The Times* he would find on comparison that the criticisms of the Telephone Administration were as numerous and as virulent under the Telephone Company as they are to-day. As far as the cost is concerned, even the questioner states that this is only twice as great. Now what other commodity has advanced only this much in price? The Post Office Services as a whole have only increased to double the pre-war prices—truly a triumph of National Organisation! But he—the lecturer—did not suggest that the present constitution of these Services was his ideal or represented the final word in the matter.

Mr. Webb added that, in our ills as in our advantages, we have short memories, and sat down amid loud and prolonged applause.

We hardly need remind our readers with any particular insistence that these are the opinions of Mr. Sidney Webb and not of Mr. Laws' Webb.

MR. J. ROWLAND KNOX, says our Plymouth correspondent, has pointed out the difficulties to be overcome by those managing telephone concerns in the East. We also have our difficulties in the West, as will be seen from a perusal of a letter received recently, copy of which I enclose:—

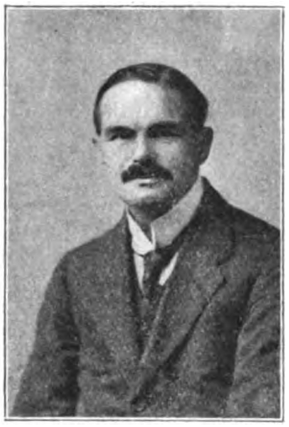
Sir,—The Post Office X——having a Phone and the Price 3d. Pence for a call I was ring up 3 times and they would not let me know anny thing about it unlett my made went thir to by sumthing I was not awair of the call.

I also have got a sister in law loking to be a mother I sent and asked if she was taking ill in the night if I could use the Phone and Mrs. X—— sead I would not be able to use it after 10.30 at night. it being the only Phone at X——, would you kindly let me know whate is to be done if my sister in law was to be taking Ill I could not ring for a doctor ore the nurces of X—— Street.

hoping you will see in to the matter

Your turly

from the Wife of Paymaster Commander X—— R.N.



EDISON, says the *Sporting Times*, is trying to get into telephonic communication with people in the next world. As if there was not already enough trouble trying to get into telephonic communication with people in this one!

FIFTY YEARS OF STATE TELEGRAPHS.*

BY A. J. STUBBS, M.INST. C.E. (*Assistant Engineer-in-Chief*).

I propose in my treatment of the subject of my address to-night to approach it rather from a historical than a propagandist viewpoint; to deal with the facts, the actual happenings, the growth and development of the art while Telegraphs have been under Government ownership and control; rather than to make a case for or against and to show that State monopoly in Telegraphs is or is not calculated to retard progress.

I cannot but be conscious that my subject really needs the genius of an F. E. Baines and the "psychology" of a John Lee to express the entrancing romance with which it is really saturated. I can only hope that as the duty has fallen to me the few dry-as-dust details that I submit will be invested by your imagination with the halo that is its due.

Early History.—Now in a historical survey, just as in a physical survey, a base formed between distant points is best calculated to facilitate accuracy of observation; and it may, therefore, be helpful if we look back beyond the period under actual survey to see the method of progress by which the position attained by the companies at the time of the transfer had been reached. We need not look far back to the dim past when flickerings showed where able men were working to produce the light, but only to that clear and certain light that gleamed from a little office at Euston Grove (Euston Station), where, in 1837, after much experiment, William Fothergill Cooke and Professor Charles Wheatstone demonstrated to the London and Birmingham Railway Company the practicability of sending signals by electricity for business purposes. I have a photograph of an account against the "London and Birmingham Railway Company" from William and Lewis Cubitt for sundry works done at the Euston Grove Station and attending upon Mr. Cooke. The circuit was run from Euston to Chalk Farm. The 5 needle instruments used were the progenitors of the Single Needle.

Wheatstone and Morse. We quite justly in England recognise Cooke and Wheatstone as the fathers of practical telegraphy; but it is well always to remember that knowledge is international and that progress in one department is rarely due to the work of one man. In more recent years this has been exemplified in the patenting upon one day of a telephone by Thomas Alva Edison and by Alexander Graham Bell; and in the development of the Radiographic system by many workers which culminated in the revolutionary work of Marconi. The same conditions existed 50 years ago, for while Cooke and Wheatstone were developing their needle telegraph in England, in the same year Professor Samuel Finley Breese Morse in America produced before Congress his famous Embosser. Two years before he had been appointed Professor of Arts of Design in the University of New York. This Morse embosser was improved by Thomas John, who invented the Ink Recorder in 1854. I suppose we ordinarily think of the *Sounder* as Morse's invention. It is not. Writing in 1880, Preece described the Sounder as "a self-invented system which is creeping gradually into very extensive employment. It is almost universal in America and very general in England. There is no record of its introduction, but I believe that it originally came into existence in America about 1851." We really had the same class of development with the Needle Instrument, which operators learned to read by sound and then added tin plates to make the reading more certain.

Telegraph Companies.—From that experiment at Euston Grove the practical usefulness of the telegraph became recognised and from time to time various companies were floated to introduce fresh development and inventions. One of the most flourishing and progressive was the Electric Telegraph Co., which later became the Electric and International. It was incorporated in 1845, and about that time it built offices in Founders Court, with galleries on right and left of the public hall. These galleries were used for administrative as well as operative purposes; but the eastern galleries left their title to telegraph instrument rooms for half a century, and even now, after lapse of three-quarters of a century, many a man speaks of the great floors of the Central Telegraph Office as the galleries. The Electric Telegraph Company continued to use the single needle, but adopted also the Morse writer. The United Kingdom Company followed the Electric Telegraph Co., but had also a few Hughes instruments. The British and Irish Magnetic Co., used the Bright's bell which, it is interesting to note, had as its prototype the aural form of Steinheil's telegraph of 1837. Another company was the London and Provincial, which used the single needle. Their single needle transmitter was of the drop-handle type. The two tapper commutator is peculiar to the Post Office, having been designed by Theiler at Mr. Culley's request, soon after the transfer (Engineer-in-Chief 1870—1878). These and the Universal Private Telegraph Co., were the principal companies existing in 1869: but there were also several smaller companies.

Thus, gradually the telegraph system spread until men came to recognise that it was an important factor in the social, and an essential in the commercial, life of the nation, and some genius (or several) conceived the idea of Government ownership under control of the Post Office. Of course such an idea was strenuously opposed. It first saw the light, according to Baines, in 1852, being the subject of a paper by Captain Galton. Baines himself appears to have framed a full scheme in 1856; but vested interests of all sorts had to be overcome, and it was not until the general public became thoroughly convinced that the telegraph was a national necessity that the proposal could get serious consideration. The mainspring of the movement for the aquisition of the Telegraphs by the State was the public expectation that the Post Office would be able to provide for the benefit of the nation as a whole an improved service at a rate which would bring it within the reach of all classes of the community.

Companies' Charges.—The United Kingdom Co. had attempted to introduce a uniform 1*s.* rate for any distance, but had to revert to distance rates. In 1869 these were 20 words for

1*s.* up to 100 miles,
1*s.* 6*d.* up to 200 miles,
2*s.* over 200 miles in Great Britain; to Ireland 3*s.* to 6*s.*

These charges were subject to an extra payment if two or more companies were concerned, and also to extra charge for delivery beyond a limited radius.

A large number of offices were at railway stations, a natural result of most of the telegraph routes being on railways, and "town offices" were opened only at the great business centres. For instance, in Edinburgh the competing companies' offices were within a half mile radius circle, leaving the rest of the city with no provision whatever.

Restricted Use.—Stockbrokers, betting men and others engaged in speculative business were the chief patrons of the telegraph, but as stated by Mr. Scudamore "the general public, puzzled by a variable and complex tariff, and disheartened by the distance of the telegraph offices from their doors, had got to regard the telegraph as a medium of communication which they might use in times of sore necessity and then only, and to look upon a telegraph message with a feeling amounting to fear."

So step by step the idea of State ownership and Post Office control marched forward, until in 1867 the Government decided that it should be accomplished, and Frank Ives Scudamore, Assistant Secretary to the Post Office, who (by instruction of Postmaster General Lord Stanley of Alderley) had been working to this end since 1865, found himself with orders to go ahead with the scheme.

Telegraph Transfer Act.—It is curious to observe that the Act of 1868, which authorised the Postmaster General to acquire the business of inland telegraphs, did not confer any monopoly of telegraphic communication. This, which was so obviously the crux of the whole matter that it is difficult to believe its omission at any stage, was provided for in the Act of 1869.

The actual physical transfer took effect on Feb. 5, 1870—the jubilee of which is marked in my mind as a lost opportunity, an occasion the celebration of which would have afforded the Post Office a golden opportunity of proving to the British public, and indeed to the world, that the Post Office Telegraph and Telephone System is by no means the effete and unprogressive institution that some critics would have it believed.

When, in 1891, we celebrated the jubilee of the introduction of the Penny Post—now, alas! departed—it evoked so much interest and enthusiasm that the profits that accrued from the celebration benefitted the Rowland Hill Fund to the amount of £22,000.

Cost of Telegraph System.—The arbitration for the settlement of terms was not concluded until 1879, a marked contrast with the time taken to clear up the National Telephone Company transfer of the telephone system. What a costly business that settlement was! When the total bill came to be footed up it showed a Capital account of £10,948,173 the main items of which were:—

Paid to Telegraph and Railway Co's.	£7,808,000
Cost of Extensions: charged to capital account until 1873	2,132,000
Buying out Vested Interests	190,000
	£10,130,000

Mr. Baines gives in a sentence a little insight into the conditions of purchase. He says "To the Electric and International Telegraph Company was paid a sum of £2,938,826 9*s.* That was the statutory compensation to a company whose property in 1856 stood in the market at no higher value than £566,080 plus some debentures." No wonder the opposition to the transfer collapsed! and no wonder the Telegraphs have never paid!!

* A paper given before the Telephone and Telegraph Society of London on Nov. 15, 1920.

Transfer.—So, on Feb. 5, 1870, the Right Hon. The Marquis of Hartington being Postmaster-General (Dec. 30, 1868-Jan. 24, 1871); Sir John Tilley, Secretary (March 15, 1864—April 3, 1880); and Mr. Frank Ives Scudamore, Second Secretary to the Post Office (1868-1875), the State Telegraph Department of Great Britain and Ireland opened its doors for business. Its example has been followed by every civilised State, with one exception. I remember being taken that day by a big brother to see the outside of one of the new Postal Telegraph Offices. Little thought I then that ten years later I should become and for over 40 years remain an insignificant speck in that mighty atom of Postal Telegraphs. Then my chief interest was in such telegraph stories as that of the old lady who carefully addressed a new pair of boots to her son and hung them for transmission on the telegraph wires; no doubt hoping to "diddle" the Post Office on telegrams as her forbears had many a time done on letters in the days before Sir Rowland Hill.

The Day of Small Things.—May I take my own entry into the Engineering Department as something of a datum. Only the year before, Graves (Engineer-in-Chief, 1878 to 1892) had certified the last of the accounts relating to the transfer. His headquarters staff numbered about 18 technical and clerical, all told. Preece's section of the staff occupied rooms 110 and 111 on the third floor. The remainder of that floor was occupied by Mr. Fischer (the Controller of C.T.O.) and his staff; the "Galleries;" the Medical Officer; and probably some other departments. The rest of the Engineer-in-Chief's staff was in the range of four rooms on the ground floor facing Newgate Street; and the Postmaster-General, the Secretariat and the Receiver and Accountant-General shared the rest of G.P.O. (West). In 1876 a Select Committee of the House of Commons, referring to the appointment of Mr. Baines as Surveyor-General of Telegraphs, said, "he might be assisted by an efficient engineering officer as Inspector-General of Lines. . . . An electrician might also be appointed. [They evidently could not otherwise provide for both Graves and Preece.) The principal re-organisation which the Committee recommend is that there should be no separate engineering department as a distinct branch of the Telegraphic Service, but that the engineering officers, etc., . . . should culminate in the Surveyor-General." The Surveyor-General is no more, but in these days, the Engineering Department would constitute a pretty big base upon which the Surveyor-General could "culminate"!

Sometimes now when I hear the striking of the C.T.O. time bell, I think of those days, nearly 40 years ago, when it fell to me to make that same bell "ring" instead of "clang." Some of you will think that my effort was not entirely successful, but there are not many other electric bells of that date that are still on active service to-day!

Statistics.—Here let me work off a few statistics about the transfer I will take my figures from the Postmaster-General's report of 1880. As in seeking facts in this connexion, I have found not only that figures can *prove* anything but that they can *be* anything, I quote my authority!—

	1869. (Companies.)	1870.	1920.
Offices	2,488	2,800	13,967
Instruments	2,200 (presumably for the 1,992 companies' offices.)		21,193
		1869-70.	1920.
Route (miles)		5,651	
Wire (miles)		49,990	*3,739,566
Submarine Cable		139	†19,556
Staff—			
Men	2,035	25,645	
Women	479	350	
	2,514		‡25,995
Messengers		1,471	
Messages		6,500,000	94,004,000
Parliamentary News, words per diem during Session...		6,000	

* Includes Telephone wires.
† Includes Atlantic cable.
‡ Includes only Engineering Department staff.

Preparations.—Of course great preparations had to be made prior to the transfer, and these were carried on to such good purpose that in time for the transfer the number of railway offices transacting public telegraph business was increased from about 500 to nearly 1,800 and 1,000 Post Offices were opened for telegrams. Re-organisation, of course, played a very important part in the development. Duplicate offices were closed, leaving circuits available for other purposes, omnibus circuits which had been the rule with the multiplicity of companies were converted to direct main circuits, such circuits being fed by omnibus circuits obtained by re-arrangement and the building of minor sections. Extensions were made in all directions so as to make of the whole a balanced national system. The plan of campaign is very interestingly described by Baines in his "Forty Years at the Post Office."

By the end of 1871 the system comprised over 5,000 offices with over 6,000 instruments and 83,000 miles of wire on 22,000 miles of route.

Growth of Messages and Mileage.—The growth of telegraph traffic during the past 50 years and the relative growth of the mileage of wire used for message purposes are shown by the curves. As regards messages the numbers are:—

1870	8,606,832
1871	9,850,000
1872	12,473,796
1884	32,843,120
1885	33,278,459

then on Oct. 1, 1885, the 6*d.* tariff (like the Penny Post, since killed by the War) was introduced and the numbers went up—

1886	39,235,813
1887	50,243,639

until the 6,500,000 of 1869 had become in

1915	91,179,000

By that year (1914-15) the 2,500 telegraph offices of 1869 had increased to 14,222, half of which were being worked by telephones.

C.T.O. "Records."—One of the picturesque incidents of State Telegraphs may perhaps be mentioned here in connexion with statistics—Queen Victoria's Diamond Jubilee (1897). Special arrangements were made, with the co-operation of the Cable Companies, for the transmission of a message from the Queen to the British Dominions beyond the seas, and immediately before Her Majesty left Buckingham Palace to join the great procession to St. Paul's Cathedral, she pressed a button which gave the C.T.O. the signal for despatch of the message. *I* know that there are at least *three* press buttons which their owners say she pressed, although *she* thought she only pressed *one*! Incidentally the previous day established a record at that date of messages from the C.T.O., the total number being 195,411 telegrams. "Records" of business at the C.T.O. appear to be generally associated with the relations between the nation and our Royal House. Besides the Queen Victoria's Diamond Jubilee, 195,411, we had Queen Victoria's Funeral, 199,155; and the postponement of King Edward's Coronation in June, 1902, the numbers on June 23, 24 and 25 being respectively 201,559, 311,039, 314,126. However, the latest "record" for messages was on Sept. 29, 1919, when the Railway Strike gave C.T.O. the job of handling 355,353 messages—close on double the Diamond Jubilee record! The present normal day's work is 120,000 to 165,000 per diem; and about 90,000,000 per annum.

Inter-Relations of Post and Telegraph.—It is a characteristic of the British nature to disparage its own work, and to do less than justice to its own institutions. I was recently impressed in reading some article in a United States journal upon the development of telegraphy, to find at the end of almost every paragraph, "Again American genius was equal to the occasion," or words to that effect. All *our* work is accepted as a matter of course, and it is only when something is wrong that we recognise it as being due to our own efforts. In Bright and Lardner's "Electric Telegraph" (1867), it is explained that the extraordinary development of the telegraph system in the United States was probably largely due to the comparative slowness and uncertainty of their postal communication. On the other hand, 15 years after the transfer the Postmaster-General explained that a very great factor in retarding the expansion of our telegraphs was the extraordinary efficiency and speed of the letter post. I believe that that same comment might be applied to-day in regard to the use of the telephone. To-day even our letter post has been deteriorated by the War—but it is a great factor still. I have often reckoned it easier to send a friend a note rather than call him to the telephone late at night.

In 1885 the development of the use of the telegraph had been so steady that we stood at the head of all European countries in messages per head of population per annum, the numbers being:—

United Kingdom ...	1.84	Germany	.66
Switzerland	1.27	Austria	.42
France	1.08	Italy	.31
Belgium	.87	Russia	.10

In that same year the National Telephone Company published a statement that their message business was equal to 280 millions of messages 100 words long! That, too, was obviously calculated to retard development of telegram traffic.

1.—*Finance.*—(*a*) It goes almost without saying that the telegraphs have never been treated as an earning epartment of the Government Service. The costliness of the acquisition cut off any such idea at the inception of the system. In the first 25 years the receipts exceeded the expenditure by nearly £1,800,000, but the interest due on capital and not paid exceeded £5,850,000. This, however, was not entirely due to the capital outlay; other items contributed, such as Press telegrams, free railway messages and reduced tariffs.

(*b*) *Press Telegrams.*—The Act fixed the price of the second and every subsequent copy of a press telegram at 2*d.* for 70 words—and copies of course were multiplied accordingly. In 1890 press messages cost the sender about 4½*d.* per 100 words, and it was estimated that this resulted in a loss to the Post Office Telegraphs of £300,000 a year, in spite of every possible effort to work the business with the utmost economy.

(*c*) *Railway Free Telegrams.*—Then railway companies, which, under their agreements with the telegraph companies who used their system, had enjoyed the privilege of sending their telegrams free, were granted the same concession over the Postal Telegraphs. Under that concession, for instance, a few years ago my negotiations for a special train for a Sunday School treat were carried out on the railway company's side by long telegraph messages delivered to my house by Post Office messengers—it saved the company stationery and stamps!

Digitized by Google

In 1869 probably the concession appeared a very innocent matter. The free messages sent in 1871 numbered 116,000. This had increased in—

1876	...	...	...	...	244,000
1880	...	...	...	...	432,000
1890	...	...	...	...	1,535,000

At this stage when it appeared that the cost to the Post Office was £80,000 per annum, it became clear that the department must call a halt; and negotiations were opened with the companies with a view to restriction of their exceedingly wasteful use of the Government plant and staff. The result was that the use gradually decreased.

In the next years the numbers were—

1892	...	...	...	...	1,554,000
1893	...	...	...	...	1,529,000
1894	...	...	...	...	1,154,000
1895	...	...	...	...	1,048,000
1896	...	...	...	...	1,339,000

when there remained but few companies with whom agreements had not been concluded. In 1919-20 the number had fallen from 1¼ millions to 922,000.

2.—*6d. Telegrams.*—On Oct. 1, 1885, the minimum charge for an Inland telegram in the United Kingdom was reduced from 1*s.* (for 20 words and address) to 6*d.* for 12 words including address. The capital expenditure necessitated for the increased plant needed to meet the increased business was £450,000, and it was estimated that the reduction cost the revenue about £170,000 a year.

In spite of the material reduction in the number of words that could be sent for the minimum charge so large a proportion of the messages was brought within the minimum that the average charge per message, which was 1*s.* 1*d.* in 1885, came down to 8*d.* in 1886. In London the local telegrams more than doubled in two years, being 1,800,000 in 1884-5 and 3,800,000 in 1886-7. The corresponding figures for the whole country were 33 millions in 1884-5 and 50 millions in 1886-7.

The 6*d.* tariff was increased to 9*d.* on Nov. 1, 1915, and this year (but after the Jubilee) a further increase has brought us to a 1*s.* minimum at 1*d.* per word.

1. *Extension of Telegraphic Facilities.*—Although money-earning was placed beyond the reach of the Post Office Telegraph System by the political exigencies of its birth the whole spirit of the Administration has from the very first been directed to giving the utmost possible benefit to the community for its ownership of the Telegraphs at the least possible cost. In 1888 a Select Committee of the House of Commons recognised that the Post Office worked in the main on business principles and added that "the high business character of the Post Office Department is in no small degree due to the fact that it has been administered in this spirit and from this point of view."

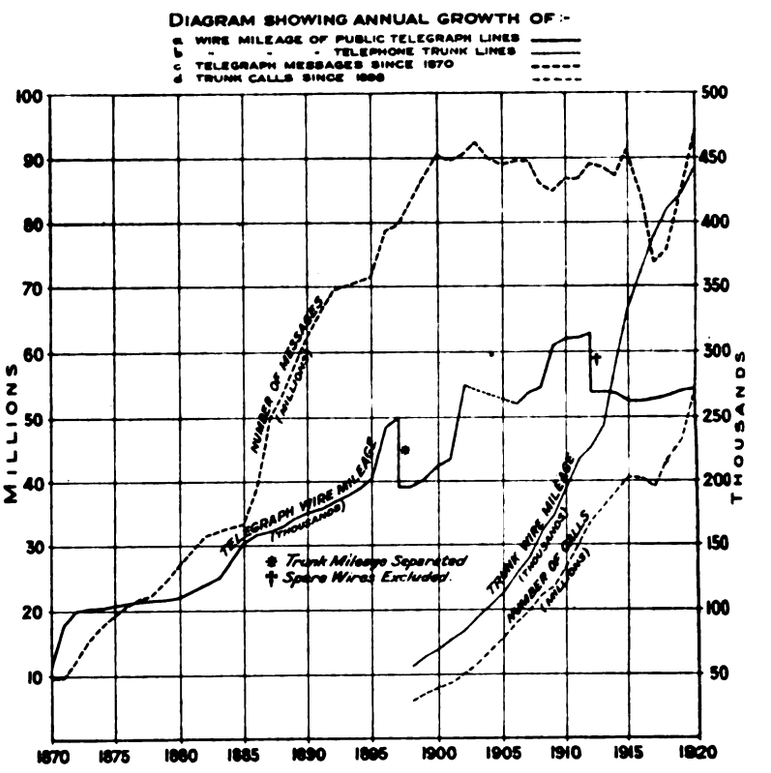
To what extent then has the Post Office attempted to meet the public expectation that it would provide an improved service for the national benefit? I will detail very briefly a few of its efforts to this effect.

(*a*) *Telegraph Stamps.*—As an obvious accounting convenience in 1876 distinctive stamps for telegrams were introduced, but they were an equally obvious inconvenience to the general public, and accordingly their use was abandoned in 1881 (Nov. 1) and postage stamps were again made valid for telegraph as well as for postal purposes.

(*b*) *Guaranteed Offices.*—In certain cases the Post Office had found it essential to call for a guarantee in respect of the opening of a telegraph office at a place which was practically certain to be unremunerative. The liability of the guarantors was often a very onerous one as it covered the whole expense including rent of the office. A great measure of relief was granted in 1891-2 by conceding that the guarantee liability should be calculated only in respect of working expenses and maintenance.

At the same time an Act was secured by the Post Office whereby Rural Sanitary Authorities were empowered to undertake the guarantee and to charge the rates with any expense incurred.

As one of the concessions which marked the celebration of the "Diamond Jubilee" of Queen Victoria in 1897, it was agreed that only half of any deficiency in the annual cost of a Guaranteed Telegraph Office should be contributed by the guarantors. This led to a great increase in such offices.



(*c*) *Delivery of Telegrams.*—(i) *Night Delivery.*—In pursuance of the policy of popularising the telegraph by simplification of the system of charging, in 1892 it was arranged that when delivery of messages was free by day it should also be free at night, although the normal delivery office might be closed.

(ii) *Extension of Free Delivery.*—To celebrate the Diamond Jubilee it was arranged that thereafter all telegrams should be delivered free within a radius of three miles from the delivery office; and corresponding reduced charges for porterage beyond the 3-mile radius were made. This was estimated to cost the Post Office £52,000 the first year.

(iii) At the same time it was arranged that within the London District free delivery should be made at all hours.

(iv) About 1908 telephone exchange subscribers began to be encouraged to arrange for their telegrams to be addressed for delivery by telephone—greatly expediting delivery and relieving the messenger service. The messages are "confirmed" by post.

(v) Another very useful development is the arrangement whereby telegrams that would be received after closing of the transmitting circuit are treated as express letters where such treatment is more expeditious than complete transmission by telegraph could be (1910-11).

(*d*) *Telegraph Money Orders.*—The great convenience of a provision whereby money could be sent by telegraph, introduced in 1889, was extended to all Telegraph and Money Order Offices on March 1, 1892. The year before the War, over £2,500,000 was so transferred under 699,000 messages. A poundage ranging from 4*d.* for £1 to 1*s.* for £10 was charged *plus* at least 9*d.* for the official telegram.

(*e*) *Telegraphic Withdrawals from the Savings Bank.*—On Jan. 1, 1894, depositors in the Savings Bank were first allowed to withdraw deposits by telegraph. It was observed that advantage was taken of this very freely immediately before and after Bank Holidays. This is another of the things shut down by the War.

(*f*) *Day Cable Letters and Week-end Cable Letters* were introduced in 1911. Day Cable Letters are accepted for delivery to places in Canada, Newfoundland, U.S.A., &c., on the next day but one after acceptance. The Week-end Letters are accepted on any day up to Saturday for delivery not earlier than the following Tuesday. The rates are respectively about one-third and one-fourth the ordinary cable rates.

(*g*) *Night Telegram Letter Service.*—At a charge of 6*d.* for 36 words it was arranged in 1912 to transmit messages between open-all-night offices after the usual posting hours to be delivered by the first post next morning.

(*h*) *Deferred Cable Messages.*—Plain language extra-European telegrams (sent mainly by people who cannot avail themselves of code) were (1910-11) provided for at half-rate, subject to liability to deferment, not exceeding 24 hours, in favour of fully-paid traffic. The scheme included Australia, New Zealand and Canada. The scheme was extended subsequently to embrace other British Dominions, the U.S.A., South America, China, Egypt and the bulk of the French and Portuguese colonies.

(*j*) *Colonial Communication.*—In 1906-7 the Post Office introduced a scheme whereby messages could be transmitted between the United Kingdom and South Africa by telegraph at each end and by post between Southampton and Cape Town.

(*k*) *Advisory Committees.*—With a view to ensuring that practical suggestions by business men for working the telephone system should get proper consideration and that well-founded complaints should receive attention, the Postmaster-General instituted Telegraph and Telephone Advisory Committees (1912). In 1914-15 there were 49 such committees.

(*l*) *Abbreviated Telegraphic Addresses.*—It appears that abbreviated addresses were used from a very early—probably a pre-transfer—date; but while addresses went free there was little inducement to register such an address. When the 6*d.* tariff introduced charge for the address, the economy of the system became so great that the schedules in London became unwieldy, and in his next report the Postmaster-General found it desirable to discourage registration as it had become the cause of delay to such messages, which had invariably to be specially treated. By 1912 the difficulty had become so acute, with 40,000 addresses registered at C.T.O., that it was agreed to give any registrant the option of adding an "Indicator" word which would automatically indicate the proper delivery office, this word not being chargeable. The concession is widely appreciated.

(*m*) *Coast Communication.*—In 1891 the House of Commons resolved that an extended scheme of Coast Communications should be developed. Time after time lack of such communication had handicapped the coastal

Digitized by Google

life-saving service, and doubtless the scheme that resulted from the resolution of Parliament has proved of immense value and importance, especially in saving of life. It was of course invaluable during the War, when it was very largely extended.

Progress of Development.—Having thus indicated the extent to which expectation of the public that an improved service would result from State control has been met, let us now consider the means by which this has been effected.

(1) *Duplex working* was scarcely known and not really needed in 1869, although devised by Gintl in 1853; but in 1873 Stearns made it a thoroughly reliable system by the application of condensers. We took it up in 1879; came to terms with the inventor for a lump sum of £2,000 a year during the continuance of his patent; proceeded to apply it to our double current system, and were using it for years before other administrations recognised its value. It was very difficult at that time to get accurately differential instruments—the manufacturer said "impossible," but the Post Office Technical Officers said "difficulties are made to be overcome" and showed the makers how!

We work duplex as a matter of course now, but in those days it was a matter for Headquarters to decide whether a circuit *could* be worked duplex. Even then the poor insulation of the lines made duplex impossible during bad weather; so the "duplex and single" switch was introduced (1874), thus providing that when duplex became impossible the circuit could be worked simplex without change of apparatus.

Duplex has always been important to us, and the purely Post Office development represents almost the entire progress in that system. In 1877 it was applied to Wheatstone fast speed working. The original "Bridge" system of duplex was revised for cable circuit working about 1890, the deficiencies of the previous practice being abolished; and in 1893 Hughes duplex, working London to Paris, was inaugurated in conjunction with the French Administration, technical officers from London conducting the trials at the Paris end.

(2) *Quadruplex.*—In 1972, Edison invented a practical quadruplex system, that Gerritt Smith proceeded to improve. Later on we agreed to pay £25 per annum for each circuit installed. Gradually all defects were eliminated, and by 1884 the "Non-polarised Relay" displaced the extremely tricky and inconvenient "Compound Relay" which was the characteristic feature of Gerritt Smith's improvement. Mr. Preece reported that at the Chicago Exhibition of 1893 it was extremely interesting to see the American exhibit of a Quadruplex set, which showed practically no development in comparison with the British exhibit, which was a practically new type in all respects.

Since then we have expanded our Quadruplex System so vastly that a mere list of the several variations is quite an imposing matter!

A Quadruplex Repeater is certainly also an imposing Instrument!

(3) *Hughes' Instrument.*—The taking over of the Submarine Telegraph Company in 1889 at once brought us into relations with Continental telegraph systems, and the Hughes' instrument. Up to that time, British practice since the transfer had left this beautiful instrument severely alone although it *had* been used to some extent by the United Kingdom Company. Its costliness and the special training for its operation barred its use here; but it was installed on all the principal Continental circuits. Invented by Professor Hughes in 1855 it had remained practically as it left his hands, except that the Germans had applied a rather more reliable governor. Its special table, its huge weight wound with great labour by a pedal, and numerous minor crudities (such as are to be looked for in an instrument fresh from an inventor) remained unaltered. In 1890 we were making Hughes' instruments in our own factory, and very soon our form of the instrument, having passed through various stages of development, appeared with direct electric drive, controlled by a rheostat designed by F. Tremain, and the motor readily detachable without interfering with the trainwork; the whole installed on a small base suitable for placing on a table. In 1893, for the first time in regular practice, the Hughes was worked duplex on the Paris circuits.

(4) *Fast Speed Telegraphy.*—(*a*) *Wheatstone Automatic System.*—The Wheatstone Automatic system was patented in 1858 by Professor Charles Wheatstone and John Matthias Augustus Stroh. I should imagine that Stroh, by his extraordinary mechanical genius, left more impression upon the form and development of British Telegraphs than any two other men. I scarcely spoke to him, but I always feel that the shadow of his genius was over *all* my design work.

At the transfer the Electric and International handed over 4 sets of Wheatstone, which worked at about 70-80 words per minute. Within ten years we had 173 circuits working at a much higher speed, and last year there were 676 Wheatstone sets in use.

The low tariff for Press messages, which proved such a costly concession made at the Transfer, was the mainspring which drove the Post Office to develop to the utmost the most economical method of conducting this unremunerative business, and accordingly the Wheatstone System was studied and expanded in every way. No detail escaped attention. For instance, probably few of those who wound up the transmitter realised that no more perfect chain has ever been produced than the driving chain that they were using.

When we remove the working part of an instrument without disturbing the driving gear, we are only copying the work of 1880 on the Wheatstone Receiver. Our multiple slip punching is the application of a principle devised in 1883—all because newspapers had a cheap tariff.

In 1890, Preece told Mat. Cooper, who was then responsible for Wheatstone working, that he wanted the speed increased to 400 or 500 words per minute. It was then 250. Acting upon a principle of design that I always tried to follow, we determined to try the simplest and most obvious device first; and within a few weeks we produced a greatly simplified form of transmitter and had it working at 600 words per minute. For long the instruction was that every morning a speed of 600 should be secured on the circuits and the working speed set at 400.

Electrical research went hand in hand with mechanical development otherwise this high speed could not have been attained.

(*b*) In 1898, Mr. Creed brought under notice his invention of a pneumatic keyboard perforator. With admirable persistence since then he has developed his system until to-day we are using not only keyboard perforators, but receiving perforators and printers that automatically print from the received slip. In spite of the restriction of such matters by the War, the extension of the use of the Creed has been extremely satisfactory,

(*c*) About 1898, our attention was called to a form of vibrating relay invented by a Dane named Gulstad. During the war supplies could not be obtained, so we applied a similar movement to one of our Standard Relays, which for our purposes gives even better results than the original. This has greatly improved the standard of Wheatstone working, being particularly noticeable and advantageous on underground circuits.

(*d*) Various other devices have been adopted to perfect this system. Duplexing of course was one of the first, then "Systematic Wheatstone" working and the gumming-up of slip from which writing-up could be done by a typewriter: but the present trend is undoubtedly toward automatic printing from the received tape.

(*e*) I have gone rather fully into this Wheatstone system as it is characteristically a British Post Office system, to show that progress in these things is not a mere natural growth but is the result of active work—a matter of pressing forward, of recognising, like the famous sculptor, that "trifles make perfection and perfection is no trifle" I want you to realise that the Post Office Engineer has set his mind upon securing that his job shall be "no trifle"; that beauty of design, perfection of workmanship and keen perception of every possibility of application of technical details, shall place and keep the work of the British Telegraphs in the absolute forefront of the art.

(5) *Repeaters.*—(*a*) The ultimate perfecting of the fast speed system, however, is largely attributable to the Post Office Repeater. It is true that before 1870 the idea of a Repeater or "Relay" was well-known as a device for introducing a stronger current at an intermediate point; but such an instrument generally actually reduced the speed of a circuit in dry weather. Our Repeaters secure an actual working speed for a long circuit that is the working speed of the worst section of the line upon which it is worked.

I should think that it would be impossible to get a group of inter-working instruments that would reasonably compare with a Fast Speed Duplex Repeater for Wheatstone working—for beauty of design, excellence of workmanship, ingenuity of application and multiplicity of technical details that are applied in order to produce the required results.

(*b*) The longest circuit ever worked in Great Britain was from Admiralty to the Rosyth naval centre, Invergordon naval centre and Scapa Flow. The length is about 900 miles and includes a submarine cable between Caithness and the Orkneys. There were Repeaters at Preston, Glasgow and Invergordon. This is, of course, insignificant compared with the circuit that was worked one Sunday about 1910 from the Indo Company's office in London to Rangoon —7,700 miles, passing North Sea cable (about 250 miles), through Berlin, Warsaw, South Russia, Teheran, Karachi, Bombay, Calcutta and Akyab. There were about 20 repeaters in circuit and the speed was 40 words ordinary Morse, with practically Post Office apparatus.

(*c*) *Sounder Silencer.*—One of the side shows of the Repeater Station is the "Sounder Silencer"—a Post Office design made to order! One day, Eden came back from a Repeater Station to say that with ten repeaters going and two sounders chattering on each repeater the clerk could not sleep at night! Put in another way, the more-or-less attentive clerk frequently failed to recognise a call because of the noise from all the other sounders. Therefore, we ought to have a device for bringing a sounder into circuit only when required. He produced one idea; Cooper made an instrument for "silencing" one sounder, and then Kempe got hot on the subject and, with the aid of the mechanic, made a model of a beautiful instrument. It worked splendidly until the clock stopped, which ensured perfect silence, with all the sounders cut out and the Repeater Station not callable! Good! Kempe proceeded to fit a clever wiper attachment that cut all the sounders *in* when the clock stopped!

(6) *Water-level Apparatus.*—That was only one of several instruments designed to order. On an earlier occasion Mr. Comport called to see the Nottingham Water Engineer at a psychological moment, when the lower part of the town had been flooded by overflow of the reservoirs. The Engineer explained that the pumping station was over a mile from the reservoirs, and if the messenger who was supposed to advise the engineman when the reservoirs were full failed in his duty, a flood resulted. Comport said: "Why not let us do it electrically?" and took the order! The first Water-level Transmitter and Indicator were the result. There are two stories about that. I will tell you one of them. When the instruments were installed the old watchman at the reservoir thought that he would not be wanted again, so they found him hanging dead behind the watchroom door.

(7) I must not pause long over the *Delany Multiplex System.* It had no chance of trial until the Post Office took it up in 1886. It was a very ingenious and flexible system, but the logic of later developments has cut it out. We improved it so greatly, perfected the various instruments, studied

Digitized by Google

the theory, analysed the working conditions, even devised a new nomenclature for its variations; and ultimately so improved and simplified the apparatus that whereas, as it came to us a hexode set at one end of a circuit comprised 43 instruments, our vastly improved installation only needed 32. Of course the inevitable happened. We at once made it double current, and then Mr. Pollock proceeded to duplex it. To-day it is only a reminiscence in the Museum! But we paid the inventor £2,000 a year while we used it.

(8) *Murray Typewriting Telegraphs.*—For twenty years Mr. Murray's inventions have been before the Department. In 1901 his fast-speed scheme provided for perforating slip by a keyboard perforator at about 40 words per minute, passing this through a special transmitter at about 120 words. The received signals operated a perforator by means of a relay, and the resulting perforated slip was then passed through a typewriting instrument which printed the message in type at the rate of about 100 words per minute. This was the first of a multitude of designs that have issued from the active brain of Mr. Donald Murray: and he is still inventing.

(9) *Other Systems.*—I cannot even enumerate all the telegraph systems that have been tried during these last 20 years. Here are some:—

1901 Rowland Multiplex Type Printer.
Mercadier Multiplex (Sounder).
1903 Buckingham Type Printer.
1904 Telepost (Morse).
1905 Pollak Virag (Photographic).
Yetman Keyboard Transmitter (Morse).
1906 Kotyra Keyboard Perforator.
Gell Keyboard Perforator.
Delany Telepost.
1908 Vibroplex Key (Morse).
1910 Siemens Photographic Automatic.
1911 Murray Multiplex.
1914 Siemens Automatic Type Printer.
Kleinschmidt (American) Keyboard Perforator (Morse).
1915 Western Electric Multiplex.

(10) *Baudot.*—The Baudot presents to my mind one of the most perplexing problems of this history. It is the invention of a French engineer, patented in 1871. The British Patent is dated 1882, but there is no known record of its ever having been brought to our notice until 1897. I think it must have been considered; (Mr. Tyrrell says it was, but not by the Engineers!) but that its radical variation from the standard Morse system, coupled with the fact that in its then form it gave no appreciably better output than the Morse Quadruplex and considerably less than the average Wheatstone, led to its being ignored. When in 1897 it was put in compeition with the Hughes, working to Paris with two channels at about 27 words per minute, its four channels averaging 30 words, it was a different matter. It still had not sufficient attraction for our Inland Service.

In 1905, however, A. C. Booth succeeded in duplexing the Baudot and the four possible channels became eight and later on ten or even twelve. No previous multiplex system has survived in practice; but this Booth-Baudot system revived the idea, and all present-day multiplex systems are based upon the duplex Baudot as devised by a Post Office engineer. We have 36 circuits now working, giving 244 Baudot channels. The use of the system is now world-wide, and there is every likelihood that its expansion in some form will continue almost indefinitely.

(11) *Non-electrical Distributors.*—(*a*) *Pneumatic Tubes.*—The old companies had commenced to develop a pneumatic tube system, and that the Department did not neglect this facility is shown by the following figures:—

Pneumatic Tubes in—		1870.	1880.
London	yards	3,887	37,144
Manchester	„	817	2,026
Birmingham	„	140	917
Others	„	—	8,533
		4,844	48,620

At present we have 100 miles of tubes, the lengths being:—

London	about 50 miles.
Manchester	„ 3½ „
Birmingham	„ 4 „
Others	„ 42½ „

In C.T.O. alone there are 4 miles of house tubes.

It is interesting to note that the first pneumatic tube in New York—between the Western Union Company's office and Wall Street—was not laid until 1876.

That the pneumatic tube service is not altogether a matter of small importance may be inferred from the fact that a scheme for working the London West End Branch Offices cost £30,000 to complete.

(*b*) *Cord Carriers, &c.*—Distribution of traffic within the office from circuit to circuit has always been a serious problem in large offices. About 1912 a "Lamson" carrier was installed at Birmingham, and use of that and other forms has been materially increased since that date. For many years previously we had forms of Cord Carriers installed to a limited extent.

(12) *Intercommunication Switch.*—A notable improvement in service was effected in 1902 by the completion at the C.T.O. of the Intercommunication Switch. This secured the through switching of about one-fourth of the work of London traffic, and greatly reduced delay. It at once saved about 4,000 message transactions per diem at the C.T.O. To-day it saves about 27,000 transmissions per diem. Major Purves was largely responsible for the development of this system.

(13) *Other Developments.*—Reference only can be made to important developments such as—

1905 Central Battery Simplex working,
1906 Decrement Quadruplex,
1907 Central Battery Duplex.

which are among many distinctive Post Office plans.

(14) *Cables.*—Telegraph and Telephone.

(*a*) *Submarine Co.*—On April 1, 1889, the Submarine Telegraph Co.'s licence expired and its system was taken over. It had cables—

5 to France,
2 to Belgium.
2 to Holland,
2 to Germany, one of which was purchased by the German Government.

The price paid by us was £67,163, including the purchase of the cable ship *Lady Carmichael*. Before that, however, we had already found the need for having our own cable ship, and in 1883 the *Monarch* was launched.

A staff of 370 was transferred.

(*b*) *German Cable.*—In 1891-2 a new cable was laid whereby the telegraph facilities to Germany were considerably improved, and direct communication, London to Vienna, was established.

(*c*) *First Air-space Cable.*—England has always led the world in submarine cable laying, and the spirit of enterprise in this respect has never been lacking in the Post Office.

The first notable attempt to depart from the beaten track and produce an air-space submarine cable was made by Mr. Willoughby Smith, and in 1898 such a cable was laid between Nevin (North Wales) and Newcastle (County Wicklow). It was not expected that it would give telephonic communication and as a matter of fact it proved unsuccessful; but it was a failure worth while in the progress of the art.

(*d*) *Paris Telephone Cable.*—April 1, 1891, marked an important step forward in the opening of a telephone circuit to Paris. Every possible precaution was taken to ensure success. The 4-wire cable was specially designed. An amusing incident occurred in this connexion. Mr. Kempe made all the necessary calculations and handed the result to Mr. Preece. The next morning a bombshell dropped—Mr. Preece had lost the papers! Kempe must make all the calculations again. "I can do that all right," says Kempe, "but it will be very awkward if the papers turn up and the figures differ!" Preece hearing this, was greatly tempted not to announce that the papers were found.

The land lines were of extra gauge (400 lbs.) and open wires every yard of the way except for a few test boxes, which had special leads and were placed well up the pole.

A young R.E. negotiated all the wayleave difficulties in the Southern District. In after years, as Major O'Meara, he became Engineer-in-Chief (April 1907 to March 1912). I was assured that in London negotiation of the overhouse wayleaves from Cannon Street Station to C.T.O. took all the time of an engineer for nine months. When I hoped he did not suffer a nervous breakdown my remark was taken as sarcasm!

The result so far exceeded expectations that it gave a real impetus to the subject of Continental communication.

(*e*) *Loaded Cables.*—During 1911 we laid a coil-loaded cable to Belgium, and the next year a continuously-loaded cable was laid by the French Government between France and England.

(*f*) *Cable Sheath.*—Non-corrodible steel. When supplies can be obtained the usefulness of non-corrodible steel is already demonstrated. For instance, its use on a submarine cable now required would reduce the weight of the cable by 7 tons per nautical mile, giving it also corresponding greater flexibility.

(15) *Synchronisation of Clocks.*—A scheme by which the Post Office undertook to synchronise public and private clocks was perfected in 1913 but its full realisation was prevented by the war.

(16) *Secondary Cells.*—I do not clearly remember who installed the first experimental set of Secondary Cells for working the telegraph circuits at Birmingham. The charging was done through about two dozen ordinary 2-way switches; but I originated the first permanent installation there and following it immediately by application of that system to the new office at Leeds, which comprised a complete design, including standard wiring of the test board and the tables. That was in 1896, and the same year we installed Newcastle and hand in hand Bristol, Cardiff and the C.T.O. The installation of the Central Telegraph Office was completed in 1898, when 772 Secondary Cells displaced 25,000 Primary Cells. As the design of the Secondary Cell System has more than once been attributed to the late Engineer-in-Chief, it may be of interest to note that he did not join the Engineering Department

Digitized by Google

until Oct. 1898. He was the first Engineer-in-Chief who served as a telegraphist. Major Purves designed the rotary form of switch while I was still in charge of designs.

(17) I feel forced to omit from this review matters that are not strictly telegraphic, even though they are electrical engineering.

(*a*) For instance, in 1883 we installed "the new *electric light*" at Glasgow and tried it tentatively at the C.T.O.—no bad criterion of the progressiveness of a Government Department, seeing that at that time (or later) Preece was running his own installation at Wimbledon and acting as adviser to the Corporation of London on the subject. It was he who suggested tall standards in the centre of the road for lighting purposes.

(*b*) But there are electric trucks, band carriers, and a host of other devices—even an electric railway—to bear witness that the Post Office is out for live business procedure.

(18) *Bicycles for Messengers.*—Such a detail as the introduction of the use of bicycles for telegraph messengers in 1897 is not without some interest as an item of organisation. It was probably one of the factors in determining extension of the free delivery radius which took effect the same year.

(19) *Construction.*—(*a*) I should like to say much about construction, as our system is without any possible doubt the most scientific and the most thorough in the world. Our practice is followed by the railway companies, was practically adopted by the late National Telephone Co. and is recognised as standard throughout the Empire.

I must however, leave the whole subject, with one exception.

(*b*) *Copper Wire.*—The British Administration led the world in the introduction of the use of copper wire for telegraph open wires. It was a bold step—a stroke of genius. I remember when Preece was retiring telling him that I always felt that to be one of the greatest things he ever did. The old man was evidently pleased. He beamed and replied: "I never had such a devil of a fight in my life!" Remembering the economical idiosyncrasy of the Engineer-in-Chief of that time, I could well believe it!

At first the wire was of poor conductivity and worse strength. To-day, with mild steel wire having a breaking weight of about 24 tons per square inch, that of copper is 28 tons; and that with a conductivity of 100 per cent. of standard. The Post Office specification has been adopted as the British Engineering Standard Specification.

(*c*) Please let me make one more exception, as a tribute to a dear old friend. The Screw Insulator was the invention of a P st Office man. It is known and used all over the world to-day—one of the neatest and most useful of engineering devices. Yet J. H. Cordeaux, who retired as Principal Technical Officer to the Post Office, was a splendid business man—but not really an engineer.

(20) *Standardisation.*—Engineering standardisation is one of the most insistent demands of modern engineering practice. Long before it came to the front the Post Office insisted upon its observance. "Standard" Relays and "Standard" Terminals date from how much over 40 years ago I cannot say, but they represent not so much a stock title as a recognised principle of procedure that has been consistently adhered to and has been of the utmost advantage to the Service.

So too with apparatus generally, as well as with Line stores and construction work. "To British P.O. Specification" is accepted as the high-water mark of telegraph engineering practice.

(21) *British Industry.*—One other merit we may claim—we have *made* a British industry. Even now British telephone manufacture cannot compare in development with that of the United States, where one concern is at the present time adding 100 acres of works to its existing 220 acres. But to the limit of its response, the British industry is utilised, and encouraged to do more. Possibly the manufacturer would like a better guaranteed regular demand, but this it is more than difficult to give while so much uncertainty prevails both as to probable cost and possible output.

Wireless.—(1) Preece's Electro-magnetic System.

(*a*) Observation of inductive overhearing between some underground circuits in the neighbourhood of Gray's Inn Road and some near-by overhouse wires first suggested to Preece (in 1884) the idea of inductive wireless. The first experiments across the Solent were promising, and then in 1901 some further experiments between the South Wales coast and Flat Holm—an island in the Bristol Channel—showed the scheme to be practicable. I rather fancy that some preliminary experiments were made by Mr. A. W. Heaviside across the Newcastle Town Moor; but I am not sure whether they were not supplementary.

(*b*) Early in 1895 the cable to the Island of Mull was broken down, and Preece's system was installed to carry on until the cable could be repaired.

(*c*) Similarly in 1897, the War Department secured communication without a cable to an outlying island 3¼ miles distant.

Some circuits on this system continued to give good service for years after Preece retired.

(2) *Wireless Telephony.*—I wonder how many people know that the British Post Office was the first to work a wireless telephone circuit. It was in 1899 that the need for telephonic communication was pressed for between the Skerries Rock Lighthouse and the Island of Anglesey. Cable had proved extremely difficult to maintain, so Preece decided to try his electro-magnetic wireless system; and it worked, but the open wires could not be maintained on the rock. The same year we worked wireless telephones between Bally Castle and Rathlin Island on the north coast of Ireland.

(3) *Marconi.*—(*a*) In 1896 a young Italian came to England with a new telegraphic invention. Whether he had a letter of introduction or not, he soon got into touch with Preece, and found him—not a man with a rival system which had to be defended—but an enthusiastic seeker for any improvement. Preece was like that; I have heard him declare that he would be delighted to take Kelvin, Sylvanus Thompson, Ayrton, and all the rest of them on to his staff at any time. So he welcomed Marconi. Soon he was conducting experiments on Salisbury Plain with success over a distance of 1¾ miles. Then, after an interval for development, in March, 1897, they compassed 4 miles. Two months after they communicated between Lavernock Point and Brean Down, a distance of 8 miles. That was May, 1897.

(*b*) The same year need for development of communication with outlying lighthouses and lightships led to experiments with Marconi apparatus, "but, although signals were successfully transmitted a certain distance, no practical results" were achieved.

(*c*) In 1900 we got good results between Mumbles Head and Ilfracombe—a distance of 25 miles; and later in the same year we were experimenting between Holyhead and Howth—56½ miles.

(*d*) In December, 1901, Marconi, at St. John's, Newfoundland, received a signal from his station in England!

(*e*) By 1911 it had become practicable for any one to send a telegram from any Post Office in the United Kingdom to a passenger on any Atlantic liner fitted with Marconi apparatus at any time during the voyage between Great Britain and Canada or the United States. Think of it! Ten years after we had just *managed* to work a distance of 25 miles.

(4) *Other Systems.*—(*a*) In accordance with our regular practice, however, other inventors were not only not discouraged, they were given every possible encouragement. In 1902-3, for instance, we had under trial wireless systems by

Slaby-Arco
Hozier-Brown.
Maskelyne.
Lodge-Muirhead.

No Wireless syndicate can show such a record as that.

(*b*) It goes almost without saying that in due course every other system—and indeed every other promising device—has been carefully examined and considered. Names of Inventors that occur are:—

Bela Schæfer,
Fessenden,
de Forrest,
Tosti-Bellini,

besides those of many of our own experts.

(5) *Post Office Control.*—(*a*) The Wireless Telegraph Act of 1904 gave to the Postmaster General control of the installation and working of Wireless in the United Kingdom; and provided that British Ships in territorial waters must hold a license from the Post Office for installing and working an approved system.

(*b*) In 1909-10, the Post Office acquired control of all coast wireless stations for ship-to-shore communication. The Postmaster General reported that it was hoped that before long there would be a ring of thoroughly equipped stations round the coast of the United Kingdom and added: "The system . . . is likely to prove of the greatest possible value to shipowners as well as to passengers by sea, and I think that shipowners will be well advised to proceed as rapidly as possible with the equipment of their vessels."

(*c*) Ever observant of the interests of the "men who go down to the sea in ships," it was on the initiative of the British Government that in 1912 special regulations were made by the International Wireless Conference with a view to prevention of disaster at sea and to the observation of distress calls.

Encouragement of Inventors.—(1) One of the objections raised by the opponents of State Telegraphs was that invention and progress would be throttled. Perhaps in those days they remembered the experience of Sir Francis Ronalds at the Admiralty just after the Battle of Waterloo. About 1816, Sir Francis wished to submit his invention of an electric telegraph to the Admiralty (which then was in control of such matters) but he tells us that, without having seen it or having it described, the Admiralty advised him "that telegraphs of any kind were then wholly unnecessary and that no other than the one then in use would be adopted." He felt little disappointed, as it was well known that "telegraphs had long been great bores at the Admiralty."

(2) Memory of this State Department's treatment may have justified the fears of 1869: but twenty-five years later, the Postmaster-General thought the idea was dead; he referred to it and summed up: "to this contention the progress achieved by the technical Department of the Telegraph Service is a sufficient answer."

(3) Not at all! Twenty-five years later still the notable *Times* Commissioner found it possible to say:—

The Post Office monopoly "has been used with disastrous effect to check and harass the development of the Telephone and of Wireless . . . But nationalisation . . . creates vested interests which oppose progress and prevent the development of new ideas, new inventions and new industries."

Digitized by Google

I wonder where he got *his* memory from? I challenge him or any competent person to mention a single telegraphic or telephonic invention of the past fifty years which has not received adequate and even generous consideration from this State Department, and would dare even to challenge such a person to point to any administration, State or commercial, telegraphic telephonic or any other "ic" that has more generously or more adequately met its liabilities in this connection.

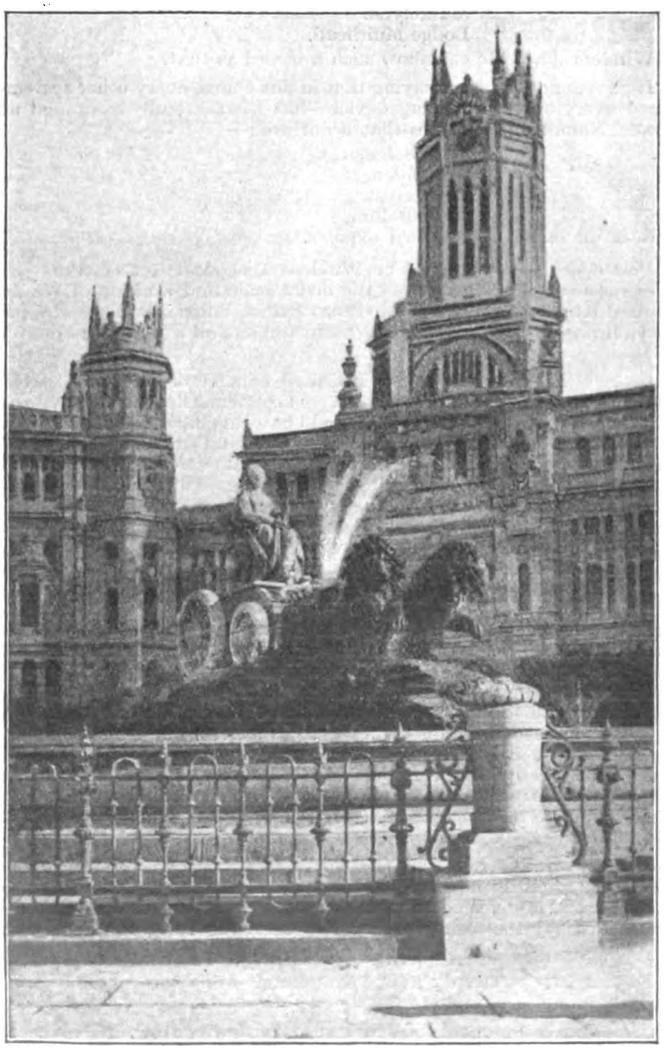
(4) Not to over-multiply illustrations of the attitude of the Department towards invention, it may be excusable to note that amongst the experiments of one year (1900-1) we tried :—

The Telautograph—an instrument for reproducing actual handwriting at the distant stations.

The Telepantograph—an instrument for transmitting actual drawings to a distant station.

The Telegraphone—an instrument for recording and facilitating the study of telephonic currents.

The Oscillograph—an instrument for recording the minute effects of undulating currents.



What a curious method of stifling invention!

Here is a list of trials of telegraph systems during another year (1902-3):—

Murray Printing Telegraph,
Buckingham Printing Telegraph,
Mercadier system of Multiplex,
Creed Keyboard Perforator.

Even thus is this "Government machine with its manifold ramifications . . exerted to restrict and harass any new enterprise."

(To be continued).

HEADQUARTERS OF THE POSTAL AND TELEGRAPH ADMINISTRATION, MADRID.

LONDON TELEPHONE SERVICE NOTES.

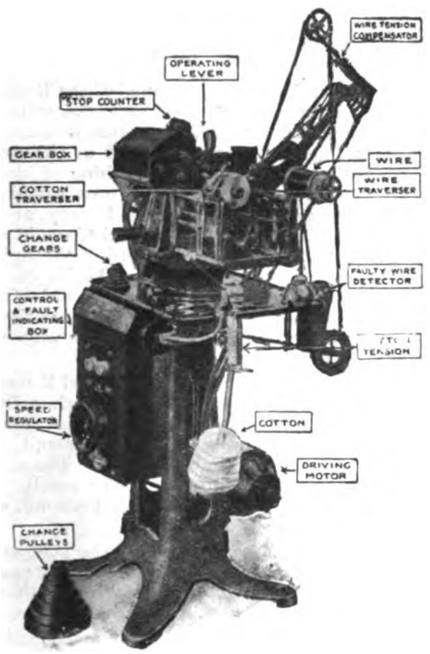
Langham Choral Society.—In presenting Berlioz's "Faust" *our* Choral Society had the good wishes of all lovers of music. The work is one of great merit, and being so seldom sung the opportunity to hear it on this occasion was grasped by a large number of admirers. The difficulties of the work are well known and militate against its more frequent performance even by choirs of long standing. The boldness of the Langham Choral Society in undertaking the work, seeing that this is only the commencement of its second season, called forth the surprise of many. That they were justified in their ambition is established by the success achieved, and the result testifies to the care and enthusiasm which must have been expended by all—Choir, Orchestra and Conductor—in effecting so creditable a performance. The easy and fluent rendering of the choruses in Scene II was particularly noticeable and the clear enunciation throughout by the choir is a point on which they deserve much compliment. The men did exceedingly well in the Easter Hymn, and that item stands out prominently as their best effort on this occasion. The men were unfortunately labouring under the disadvantage of lack of numbers, a factor for which they are not responsible, and which had the effect of dwarfing the merit of their performance. It is hoped that they will not continue to suffer this disadvantage, but in spite of it the Society will undoubtedly occupy a prominent position among other similar societies. The orchestra performed its part splendidly and its rendering of the "Rakoczy March" and the "Ride to the Abyss" calls for special mention. The audience numbered over 2,000 and at the conclusion one heard on all sides comments of real appreciation.

The society now enters on a period of preparation for another work which it hopes to present in February next; meanwhile a most earnest and pressing invitation is issued for additional male voices.

London Telephonists' Society.—Two very useful papers were read by members of the Controller's Office at the November meeting of the London Telephonists' Society, one by Miss A. M. Scott, entitled "Trunk Tickets," and the other by Miss M. H. Knights on the subject of the *London Telephone Directory*. Both papers were of an educative nature, valuable and interesting as affording to the traffic staff an insight into the work of the Controller's Office. One could not help noting the similarity between certain of the difficulties experienced in the Exchanges and in the Office. Both sides were brought to appreciate to some extent the manner in which the shortcomings of one affect the other. An exchange of knowledge between different branches closely associated in a complex organisation makes for efficiency, and for the ease and comfort of all. The Accounts Branch have their troubles with subscribers against whom debits are raised incorrectly through indistinct writing in the preparation of tickets in the exchanges, and from phonetic errors which lead to incorrect particulars on phonogram tickets. The exchanges are troubled by *Directory* discrepancies which result in such request as "Please intercept all calls for ..... 7 lines at once." Papers of this nature do not perhaps attract the largest audience, but their value is not to be assessed from that standpoint.

The members of the Society are looking forward to the December meeting when Mr. M. C. Pink will read a paper entitled "My impressions of London Telephones," by Sadie Worth, Telephone Operator, New York City.

Mr. O'Dell's Paper.—At the meeting of the Institution of Post Office Electrical Engineers (London centre) held at the Royal Society of Arts on Nov. 8, Mr. G. F. O'Dell of the Engineer-in-Chief's Department, read a paper entitled, "The Influence of Traffic on Automatic Design." The paper dealt almost exclusively with the determination of the fundamental principles for the calculation of the number of switches necessary for the traffic which may be anticipated in a particular instance. The apparatus employed in machine switching is costly, and it is therefore essential that its provision should be restricted to the minimum which will give a reasonable standard of service during the period of maximum traffic pressure (the busy hour). The volume of traffic arising during the busy hour is subject to fluctuations from a multitude of causes, small and large, causes which themselves are variable, so that the volume of traffic for a particular busy hour is largely a chance quantity. As a consequence the theoretical methods which have been employed in the solution of these problems depend on the theory of probabilities. Mr. O'Dell instanced the association of the theory of probabilities with games of chance and its use by insurance companies in computing the expectation of life. Mr. Lee, in a well-chosen speech, referred to its use also by bankers in determining the amount of fluid money required to meet the demands of their clients. Doubtless many of his hearers would be glad for someone to apply the theory to ascertain the probability of their banking accounts showing a credit balance at the end of the year!



The method of determining the relation between the number of switches and the traffic by means of artificial traffic was dealt with by Mr. O'Dell. For this purpose drawings are made from a bag of counters. Although this method may give results satisfactory to the theorist, it is feared that a subscriber who complained of inability to obtain connexion through the continued engagement of the switches would hardly be satisfied with an explanation that the adequacy of the number of switches had been tested by a method involving the drawing of counters from a bag!

Mr. O'Dell dealt with the several theories which have been advanced for the solution of these problems, and his paper constitutes a real contribution to the general knowledge of the subject of machine switching.

Mr. Pink's Paper.—The paper entitled "Automatic Telephony in Large Areas from a Traffic Point of View," which Mr. Pink read before the Telephone

Coil Winding.

No. 96 Machine insulates coils with a cross-winding of cotton yarn.

Manufacturers of Telephone, Telegraph and Wireless Apparatus, Small Motors and Generators, Medical and Domestic Appliances, etc., should be equipped with

"LEESONA" Winding Machines

(Made by The Universal Winding Company).

These Machines produce Coils far superior to any others. Automatic devices are fitted to machines to count and stop at any pre-determined number of turns, detect kinking or entangling of wire, or faulty insulating covering.

The Coils produced are self-supporting (no bobbins required), and when impregnated they become practically indestructible.

WRITE FOR DESCRIPTIVE LEAFLET, No. 1600.

METER COIL—Note the cross-winding of cotton.

American Telegraph Practice

By DONALD McNICOL,

Engineering Staff, Postal Telegraph-Cable Co., New York; Mem. A.I.E.E.

507 *pages*, 6 x 9, 421 *illustrations*.

Price 30/- net.

It describes American systems, covers modern methods of operation and compiles the formulæ used in practical telegraphy. It is built up logically from a foundation of principles to include all details of practice. It covers thoroughly, simultaneous telegraphy and telephony. Mr. McNicol has had wide experience in the servce of the Bell Telephone Company, Western Union, Postal and two of the larger railroad systems.

CONTENTS.

Preface. Introduction. I.—Electricity and Magnetism. II.—Primary Batteries. III.—Dynamos, Motors, Motor-Generators, Dynamotors, Voltage and Current Regulators. IV.—Storage Batteries, Current Rectifiers; Mercury-Arc and Electrolytic. V.—Power-Board Wiring, Battery Switching Systems and Accessories. VI.—Circuits and Conductors, The Electric Circuit, The Magnetic Circuit, Electromagnets. VII.—Single Morse Circuits. VIII.—Lightning and Lightning Arresters, Fuses, Ground Connections. IX.—Main Line Switchboards for Terminal Offices and Intermediate Offices. X.—Electrical Measuring Instruments, Telegraph Line and Circuit Testing. XI.—Speed of Signalling, Circuit Efficiency. XII.—Single Line Repeaters. XIII.—Duplex Telegraphy. XIV.—Quadruplex Telegraphy. XV.—Balancing Duplexes and Quadruplexes. XVI.—Duplex and Quadruplex "Local" Circuits, Leg-Board and Loop-Board Connections. XVII.—Branch Office Annunciators, Grouping of Way-Office and Branch-Office Circuits, Needham Annunciator, Office Signalling Systems for Multiplex Circuits. Bell Wires, Main Line Call Bells, Second Side of Quadruplex, Selectors. XVIII.—Half-Set Repeaters, Combination Full-Set and Half-Set Repeaters, "House" Repeater Circuits, Duplex and Quadruplex Repeaters, Leased Wire Intermediate "Drops." XIX.—The Phantoplex. XX.—High Speed Automatic Telegraphy. XXI. Telegraph and Telephone Circuits as Affected by Alternating-Current Lines, Transposition of Wires Used for Telephone Purposes, and for Simultaneous Telephone and Telegraph Purposes. XXII. Telephony, Simultaneous Telegraphy and Telephony over the Same Wires. XXIII.—Specifications for Copper and Iron Wire, Aerial, Underground, Submarine and Office Cables. XXIV.—Electrolysis of Underground Cable Sheaths. APPENDIX A.—References to Printing Telegraph Literature. APPENDIX B.—Specifications for the Construction of High-Tension Transmission Lines Above Telegraph Wires. APPENDIX C.—Telegraph Alphabets. APPENDIX D.—Useful Tables.

and Telegraph Society on Nov. 15, attracted a large attendance of members and visitors. Contact with machine switching problems has been the privilege of a comparatively small number of those concerned with London telephones and the attendance at this meeting and at that held by the Institute of Post Office Electrical Engineers a week previously testifies to the desire of traffic officers and engineers to become acquainted with the subject. At the present time attention in London is concentrated largely on the Western Electric Panel system as a result of the decision to instal equipment of that description for the new Blackfriars Exchange in the G.P.O. (South) building.

After referring to a number of traffic problems generally associated with the adoption of machine switching in large areas, Mr. Pink dealt with the special features of the panel system. The subject was a difficult one to present in the short time available, and it was unfortunate that the aid of a lantern was not practicable. With the assistance of diagrams, however, Mr. Pink was successful in presenting his subject in a manner which enabled his hearers to follow him without undue difficulty. For the more complete assimilation of the information which the paper contained one speaker asked that the paper should be printed, and in so doing expressed the common wish. The predominant impression left on the minds of the audience was undoubtedly that a large volume of traffic and engineering problems of varying degrees of intricacy awaited consideration, and required immediate and close attention if the application of machine switching to London is to be a success. The problems are such as to demand an adequate and highly-trained staff, not only for executive work but for individual study. The measure of success which will be achieved in London during the difficult transition period when the manual and automatic systems will be running in parallel is largely dependent on the extent to which this demand is recognised and met.

Machine switching holds out possibilities of an improved service in several respects, but at the meeting emphasis was laid on the good work done under manual conditions in the past and the large part which the manual system must of necessity play in the telephone facilities of London for many years to come. The standard of service given before the War and the general improvement which was then in progress is a matter for congratulation, and it is gratifying to note the appreciable improvement which has and is taking place in recovering the ground lost during the War. Who is so bold as to assert that the machine switching system will rise to the requirements of all emergency conditions as did the manual system in War time? Can these dry bones live?

It will be extremely interesting to watch the attitude of the public towards the two systems while they are working side by side. There is little doubt that automatics, either as we now know it, or, what is more probable, in some form which will be evolved in the course of time, will be the system of the future, and it must be an object of the Administration to take such steps as are designed to secure the favour and co-operation of the telephone-using public for the automatic system. Nevertheless the manual system must not be neglected or despised. It has been one of the wonders of its day. Its accomplishment and its limitations are known, while those of the systems to which it will give place are yet to be proved. Progress demands, however, that we shall go forward wholeheartedly, but, as Mr. Lee counsels, without undue haste, securing the maximum advantages which the development of machine-switching systems afford.

Mr. Pink's paper is a valuable contribution to the subject and general appreciation was expressed at the meeting for the able manner in which it had been presented.

* * * *

At the Investiture held at Buckingham Palace on Nov. 4, the Controller was among those on whom the King bestowed the Insignia of Commander of the Most Excellent Order of the British Empire.

* * * *

By the time these notes appear in circulation it is probable that the Christmas Fair, which Miss Heap is organising, will be over. Its success in attaining the end Miss Heap has in view is assured through the enthusiasm with which it has been supported by the staffs of all exchanges. It is very encouraging that the Queen has given the function her support by presenting a picture for sale at the Fair.

* * * *

Contract Branch.

The Contract Branch negotiated agreements for 5,679 stations during the five weeks ended Oct. 30. The number of stations recovered during the same period amounted to 1,836, leaving a net gain of 3,843 stations.

The esteem in which F. A. Peterson, the Boy Messenger, lately attached to the South-Eastern Contract Branch, was held was shown by the staff on his leaving to enter the Foreign Section of the London Postal Service as a Sorter, when an attache case was presented to him. This boy won the esteem and confidence of the entire staff by his courtesy and willing manner, and much regret was felt at his departure.

Lee Green Exchange.

A social evening eas held on Oct. 30, 1920, in aid of the funds of the War Seal Foundation. Mr. W. J. Roberts (Secretary of the Foundation) attended and made a delightful speech. The sum of £18 was realised, which brings the total amount from socials and the buying of seals up to over £100. The Lee Green staff feel proud of their efforts considering their small numbers.

Victoria Exchange.

On Oct. 15 a very jolly social evening was held by Victoria Exchange in aid of the South London Hospital for Women. The Hat Trimming (for gentlemen only) and Bun Eating Competitions caused considerable amusement. An excellent musical programme was provided, and dancing also completed a happy evening. The sum realised for the Hospital was £23 13*s.* 6*d.*

The Willow Swimming Club have commenced their winter activities. Their first whist drive, supper, song and dance was held on Oct. 30, and was voted by all "A1," with the request for another as soon as possible.

The prizes were presented by Miss Nurse, and Mr. Pounds made a happy speech. Their presence was greatly appreciated by the staff. The duties of M.C. were ably carried out by Messrs. James and Henshilwood.

Western Exchange.

"Know how sublime a thing it is
To suffer and be strong."

One wonders whether when Longfellow penned these lines he had just attended a happy function, seen a number of men executing the artistic movements of the dance, their faces reflecting health and happiness, and, turning in expectation of seeing the whole reflected in the eyes, suddenly realised that they were sightless. Yet he knew nothing of the great War. He did not know that in the years to come gallant men would rush to face the foe in the most momentous period of England's history, and that many, after having risked all and lost the priceless gift of sight, would return to live in perpetual darkness in order that others might enjoy the light. In truth these men are heroes. In an endeavour to relieve the lot of these blinded men the Western Exchange staff organised a dance in aid of the funds of St. Dunstan's and at which the guests of the evening came from that Institution. It is gratifying to record that the evening was in every way a success and resulted in raising the sum of £10 10*s.*

The Great Silence has once more come and gone, and if memories of the horrors of the War are now receding, our sightless warriors live on, and a reminder of this, such as that afforded by Western's social function, is well, "Lest we forget." A good orchestra was in attendance and from the first bar to the last kick, fun and merriment were rampant. The scene presented at the height of the dancing was a dazzling one. The pretty dresses of the ladies, with the black coats of the gentlemen for a background, was as a peep into a kaleidoscope.

When half the programme had been completed the company adjourned to the buffet to partake of the many good things thoughtfully provided by the organisers, and thereafter time passed all too quickly, so that at the last it was an effort to break away from such happy surroundings.

The Western Exchange also contributed, by voluntary collections from the staff, £30 in aid of the War Seals Mansions.

PERSONALIA.

LONDON TELEPHONE SERVICE.

The following officers have resigned on account of marriage:—

Miss M. A. SIMS, Assistant Supervisor, Class II, of Gerrard.
Miss M. F. N. CROCKER, Assistant Supervisor, Class II, of Victoria.
Miss A. J. B. PENDER, Telephonist, of Avenue.
Miss P. GITTINGS, Telephonist, of Avenue.
Miss V. M. LADD, Telephonist, of Chiswick.
Miss G. E. RANNER, Telephonist, of Museum.
Miss R. DUNLOP, Telephonist, of Museum.
Miss A. R. A. FURLEY, Telephonist, of Museum.
Miss A. FIDLER, Telephonist, of Paddington.
Miss D. MCNEALE, Telephonist, of Paddington.
Mrs. F. E. GROVES, Telephonist, of Hammersmith.
Miss G. A. PRESTON, Telephonist, of Trunks.
Miss E. ELOE, Telephonist, of Trunks.
Miss M. A. HOBSON, Telephonist, of Victoria.
Miss G. DANIELS, Telephonist, of Victoria.

OBITUARY.

Mr. F. PRESTON, formerly Superintendent of the C.T.O., was unknown to the younger generation. Having entered the Telegraph Service in 1868 at Southmapton, he was transferred to the Metropolis in 1873 and passing through the various grades, reached, in 1905, the rank above mentioned from which he retired on pension in 1911.

There is, however, still a very considerable number who were co-temporary with him through many years of his career, and who recall his *penchant* for verse-making and his aptitude for hitting off a subject with his clever pencil even as far back as the "Scudamore" period.

There was, however, something pathetic, yet tinged with the heroism, of one who always looked life and all its ups and downs fairly and squarely, in the face, to find bequeathed to the present Deputy Controller a few farewell lines headed "Gone Aloft" and commencing:—

"Goodbye, dear friends I've drained the cup,
And put to sea to join the rest."

These I have before me. They are written clearly and boldly, as he ever wrote, the simple document being signed "F. Preston, Electric and International Telegraph Coy., and G.P.O., died....," a space being left for the exact date, which fell on Nov. 11. How these dear old fellows loved their profession and were proud of it!

Owing to the inclement weather few of his old friends were able to be present at Abney Park Cemetery, but Mr. A. W. Edwards and Mr. Bullard were noted amongst the mourners.

FIFTY YEARS OF STATE TELEGRAPHS.

(*Continued from page* 44.)

The Telephone.—(1) (*a*) Now we turn to the Telephone—perhaps the pioneer amongst the miracles of modern science.

(*b*) It was twenty years and more from the time that Ronalds wished to submit his scientific toy to the Admiralty before Cooke and Wheatstone produced a practical electric telegraph Compare with this the facts that Bell's invention of the Telephone was pr duced in 1876, exhibited as a scientific toy in England the next year, and Telephone Exchanges were in full working order in 1879.

(*c*) I have intentionally referred to the Telephone of 1876 as a "toy", because it was the term said to have been used by a great predecessor at the time; and I can understand Preece's amusement at the unobservant observers who repeatedly quoted it as indicating his attitude towards a great invention! Quite recently *The Times* Commissioner quoted this old charge.

He said:—

> "The Post Office authorities, when the telephone was first brought to England, pronounced it a scientific toy, of no commercial value, and they refused to take it up."

(*d*) This is what Preece actually said when, with pride and delight, he introduced Bell's Telephone to the British Association in 1877:—

> "It is evident that in Reis' telephone everything at the receiving end remained the same excepting the number of vibrations, and therefore the sounds emitted by it varied only in tone, and were therefore notes and nothing more. The instrument remained a pretty philosophical toy and was of no practical value."

You will see that the offending word was not applied to Bell's telephone at all, but to a device that not only was then, but still is, "of no practical value."

Preece proceeds ". . . it remained for Professor Graham Bell . . . to make the discovery by which tone, intensity and quality of sounds can all be sent He has rendered it possible to reproduce the human voice with all its modulations at distant points:" And Preece ends his communication:—

> ". . . there is no doubt that scientific enquiry and patient skill will rapidly eliminate all practical defects."

What could be more scientifically sympathetic, especially in view of the fact that at the very same meeting the inventor himself said: "I do not bring this before you as a perfected invention, as it is only in an embryo state"

(*e*) Personally I suspect that Preece *did* actually use the term of Bell's telephone, although not publicly. He was by no means averse from "ragging" some of his relations; but *The Times* correspondent should know Preece's record better than to think of him as apt to stifle invention.

(2) In 1880, as the Postmaster-General said in his Report, the telephone was brought prominently under public notice by two companies whose object was "to establish what are called Telephone Exchanges . . . . The Department is advised that the system of these companies constitute an infringement of the monopoly . . . and steps have been taken to protect the rights of the public."

On Dec. 20, 1880, the High Court of Justice decided in the action of the The Attorney-General *v* the Edison Telephone Company:—

> That a telephone is a telegraph within the meaning of the Telegraph Act.
>
> That a telephone message is a telegram.
>
> That the operations of defendants infringe the Postmaster General's monopoly.

How correct this judgment was is amply demonstrated by the well-known facts of the present day that a great volume of telegram traffic is handled by telephone and that the expansion of the telephone system automatically restricts the growth of telegraph business. Although this statement is open to an obvious retort, I leave it as being substantially and essentially correct.

(3) One of the lines of argument suggested by Preece was that it could be "shown experimentally how gradual and imperceptible the transition is from a telegraphic apparatus pure and simple (like a sounder) to the telephone as at present used."

He must have been very disappointed that the case was fought on affidavits. It would have been such a joy to him to exhibit in court the working models that were to prove his case. They are only Museum exhibits now!

(4) *Telephone Policy.*—The telephone having been declared to be a telegraph within the meaning of the Act, and, therefore, within the monopoly of the Postmaster-General, it became necessary for the Post Office to decide upon its policy in the matter. This was formally announced by the Right Hon. Henry Fawcett (Postmaster-General, May 14, 1880 to Nov. 7, 1881) in 1881. He explained that the Post Office would not work the Government monopoly exclusively, but would grant licenses to approved companies in such manner as would serve best to prevent a monopolistic condition from arising. There may have been good reasons for its adoption, but an oil and water policy like that was bound to fail. The licence granted in 1881 to the United Telephone Company even authorised competition with the Exchanges of the Postmaster General himself.

(5) With such open competition, in self-defence and indeed in the interests of the new art, the stronger had to absorb the weaker. It even appeared that companies were started in order that they might be bought up. How else can one account for the launching of a "New Telephone Co.," in competition with *the* N. T. Co.? So in 1892 the position was reviewed, and it was admitted that the results had not worked according to plan.

I must confess that I am of the sceptics who wonder at but fail to believe in or admire the 11,000 telephone companies of the United States. What chaos there would have been but for the paramount influence of the "Bell" Company!

Digitized by Google

Trunks.—(1) As the local telephone service expanded the need for inter-communication between distant towns became more clamant. The National Telephone Company, having exchanges in many towns, naturally felt the necessity earliest, and was forced to provide such facilities to its subscribers. After a time it became evident that a licence to a local company was almost valueless while its rival could virtually claim a monopoly of speech communication with areas outside its own boundaries.

(2) Whether or not the Post Office realised that the trunk system was really a serious burden to the enterprising company that had developed it, I do not know. As early as 1879, Preece had urged that restriction of all licensees to operate only within the licensed area (which in those days was limited to a radius of half a mile from the exchange), and control of all trunks by the Post Office, would provide a very tight coupling with the various companies and give the Department full control of the telephone business. It was not until 1892 that the Treasury decided upon adoption of this course and that a Bill to give effect to that decision was submitted to Parliament. The Telegraph Act, 1892, was passed on June 28. At the same time the radial limit was relaxed.

(3) Authority to proceed being thus secured, the business of surveying the existing plant belonging to the National Telephone Company and assessing its value had to be taken in hand. Many an officer now holding a good position may date his success from opportunity presented and good work done at that time. In the result on April 4, 1896, the Accountant-General handed the representative of the National Telephone Company a warrant for £459,114 3*s*. 7*d*.—probably a bigger cheque than any reader has paid into his banking account for a long time! For that sum we acquired 29,000 miles of wire on 2,651 miles of route.

(4) The transfer itself was an exceedingly difficult technical matter. Every small company had employed its own chief engineer, who had made a point of introducing special features into his system. Even when the National Telephone Company had absorbed the small company they had not troubled to modify the working; so that our internal plant survey officers were constantly coming across fresh "gadgetts" as we might say now, but that the technical people at Headquarters then might have called "snags." Naturally these variations all had to be provided for in order that they might work in with the trunk communication system that we had determined upon; that is an automatic calling and clearing system. All the time we were working at heavy pressure, and I acquired a horror of dates being fixed for the transfer. At last Cooper came one day (I think it must have been about March 1895) to tell me that it had been "finally decided" that the transfer should take place on May 1. I took immediate opportunity to tell Preece that it couldn't be done. He said it must—the Secretary insisted. I explained that unless we entirely abandoned our agreed scheme the supply of so many pounds of a very fine silk-covered wire was essential, that only one firm could produce this and that at the rate of a few ounces a week—I ventured to suggest that the game of fixing dates should be held in abeyance, and that it would probably be better to effect the transfer by stages.

(5) Ultimately, the first stage of the actual transfer was reached by transfer of the South of England circuits on April 4, 1896, and the final section was taken over on Feb. 6, 1897.

(6) Of course it was not really only a matter of "transfer." Supplementary circuits were provided on an extensive scale, so as to provide a coherent scheme of trunk communication for the whole country. By the end of 1896-97 the 29,000 miles of wire, of the company's system had been supplemented by nearly 20,000 miles making, with circuits in course of construction, a total mileage of 52,800 miles; which gave over 880 separate trunk circuits. The total cost to March 31, 1898, was under £1,200,000, including the payment to the National Telephone Company.

(7) *Double Time at Single Rate.*—In 1903 it was arranged that for communication upon Trunks at night (between 8 p.m. and 6 a.m.), the ordinary rate should cover a 6-minute call instead of the normal 3-minute period.

Telephone Exchanges.—"*Active Competition.*"

1. The licensees got very little competition from the Post Office until the Telegraph Act of 1899 authorised an expenditure of £2,000,000 for the provision of telephone exchange facilities in London and other places.

This decision was arrived at to meet the ever-growing complaints of the public that the Telephone Companies had utterly failed to meet the telephonic requirements. In fact we have already tried the non-national system and it failed!

2. The same Act empowered authorities of boroughs and urban districts to work telephone areas outside the limits of their ordinary jurisdiction; subject of course to the license of the Postmaster-General.

3. *Telephoning London.*—(*a*) Again the engineers were confronted with a big work—the telephoning of London. In anticipation, Mr. (now Sir John) Gavey (Engineer-in-Chief, 1902-1907) and the late Mr. Matthew Cooper (whose sudden death in 1900 was a very serious loss to the department), visited the U.S.A. in 1898. One result of that visit was the decision to adopt the Common Battery System for the principal London exchanges. It was then being called the Central Battery System, but I pointed out the inconvenience of using that word, already extensively appropriated to designate the principal exchange of a city.

(*b*) The telephone experts of America admitted that the telephoning of London was the biggest proposition that telephone engineers had ever had to tackle, and freely said they would follow the operations with the keenest and closest interest.

(*c*) We commenced by the design of a duct system that, although too expensive for present-day general practice, has been very widely adopted by other authorities.

(*d*) Then we devised and designed manholes for footway and roadway as a more convenient and far cheaper method of handling cables than that previous adopted of leading-in to an adjoining building for distribution of cable circuits.

(*e*) The provision of a great underground system of cables all over London to meet not only our own needs but to hand over to the National Telephone Company on rental terms to enable them to carry on was a task of no insignificant magnitude. Incidentally, it involved systematic recovery of all the G.P. cable previous installed, which represented greatly increased efficiency at greatly reduced cost (1902-3).

(*f*) *The Central Exchange.*—The Central Exchange, laid out for 14,040 subscribers and opened in 1902, had only 5,847 subscribers connected, when a second exchange of capacity for 16,200 subscribers was being laid down.

(*g*) We find Central, Western, Victoria, and four Thames Valley Exchanges opened in one year, with Mayfair, Hampstead, Croydon, Epsom, Sutton, Ealing and Crouch End well in hand.

(*h*) I have an idea that people with whom the Post Office does business do not find the incompetence that is so easily discovered by *The Times* Commissioner. For instance, I wonder if the National Telephone Company, when they agreed that they would share the costs of inter-communication between the two systems when P.O. subscribers in London reached 10,000 expected that this qualification would be attained as early as 1903—the year after we started?

(*i*) *Wayleaves.*—Volumes have been or could be written about wayleaves; pounds have been spent to save payment of shillings, but until Parliament ignores private and municipal rights in property, the Post Office will continue to struggle against more impossible conditions than any other administration has ever had the need or needed the courage to face. When we came to telephoning we realised how thoroughly the National Telephone Company, with absolutely no statutory rights or powers, had "queered our pitch." Where we had grudgingly submitted to be "fleeced" for 1*s*. they had flung largesse to the receptive property owner. The effect was to take us into the Law Courts, or alternatively to thrust us underground.

We found in fact that this general stir led local authorities and private owners alike to become very jealous of their rights in regard to wayleaves and local control. One Corporation Surveyor, for instance, having agreed the "depth, course and position" of the Department's pipes in the terms of the Act, refused to allow a variation of as much as one inch from that so "agreed."

4. *Principles of Telephone Extension.*—In 1905 in giving a list of 76 places where telephone exchanges had been opened, giving also trunk communication, the Postmaster-General mentioned that at nearly all there was previously no telephone service. That represents the general sound principle upon which Post Office service of the public has been based.

5. *Telephone Transfer.*—(*a*) In 1905 an Agreement was made with the National Telephone Company which provided that the Post Office would take over by purchase the company's telephone system at the end of 1911 on the termination of the licence. Provision was made to ensure the proper maintenance and development of the system meantime.

Here again I may not wander into the fields of surveying, of accounting, of collating, of conferring or (more attractive still) of anecdoting upon which a whole campaign was fought out. It has matter for a volume by itself.

(*b*) It must suffice to note that at midnight on Dec. 31, 1911, the addition of the National Telephone Company's great system to the not inconsiderable existing system of the Post Office became an accomplished fact. So far as I can make out deterioration of the Service commenced one minute later and has progressed ever since!

(*c*) The figures for the plant transferred compared with the then existing Post Office plant give some indication of the problem that the amalgamation must necessarily have presented:—

	N.T.Co.	*Post Office.* Mar. 31, 1912.
Underground.		
Miles of conduit	3,435	5,728
Miles of wires	827,400	705,650
Overhead.		
Poles and standards	No. 423,300	miles 53,105
Bare wires—miles of wire	258,500	298,401
Aerial cable	110,000	—
Submarine:		
Miles of wire	—	2,249

(*d*) The Company transferred 1,565 exchanges, having about 562,000 subscribers' telephones. This brought our total of exchange subscribers' telephones to 704,000.

(*e*) The price finally paid to the company was £12,470,264. The company's original claim was £21,046,7000 and the Post Office estimate £9,381,048.

Growth of Plant and Traffic.—It will be of some interest to compare figures for the year after transfer and corresponding figures for last year for both trunk and local services:—

Trunks.	1897.	1920.
Miles of wire	52,800	441,092
Trunk calls	5,898,247	54,049,389
Average cost	5.45*d*.	8.4*d*.
Local exchanges.	1913.	1920.
Miles of wire	2,199,951	2,806,971
No. of subscribers ...	704,000	—
Calls	797,000,000	848,500,000

Digitized by Google

Automatic Working.—1. *Automatic Signalling.*—Under Preece's guidance the British Post Office was far in front of all telephone administration in its recognition of the value of automatic working, and even as late as 1897 we could record that experts constantly expressed surprise and admiration at the extent to which we had perfected automatic signalling.

2. *Automatic Switching.*—(*a*) The first automatic switch was brought to this country in 1899. I did my best to induce the Department to install one as an official switch so that we might be in touch with its development. Scribner, the inventor, said that if we had one we must take over one of their trained mechanics to maintain it, and it was decided that we had better hold our hand.

(*b*) At the present time, however, it is a fact that we have in actual use not only samples of all promising types of automatic switchboards, but also that our percentage of automatically-operated subscribers 'sets to the total number is higher than that of any other telephone administration in the world.

Minor Developments.—(1) *Continuous Day and Night Telephone Service.*—The Post Office at a very early date aimed at an "open always" telephone service, and by 1914-15 of 3,052 exchanges, only 357 had any restriction in regard to the period of service.

(2) *Trunk Service.*—It was an obvious inconvenience that trunk communication should have to be originated in a building quite distinct from the local exchange. In 1912, at the time of the telephone transfer, there were 293 such cases; by 1915 this number had been reduced to 83.

(3) *Reply-paid* Vouchers.—Telephone subscribers who usually dictate their telegrams by telephone may use reply-paid vouchers in payment of accounts for telephone fees, &c. (1912).

(4) *Spelling Code.*—There is, I fancy, one little detail of instruction of the operators who transmit telegraph messages by telephone that might be improved upon. I refer to the method of using the code, which is meant to help operators to get difficult words through. This is how it works. I had a service call the other night. The operator said: "Here's a long message in French, will you take it?" "Go ahead!" and he did, something like this:—

> T for Thomas; E for Edward; L for Louisa; L for Louisa; M for Mary; E for Edward; W for William; H for Harry; A for Alfred; T for Thomas; I for Isaac; T for Thomas; W for William; A for Alfred; S for Sarah.

That was not the message. Probably most of you can TELL ME WHAT IT WAS, but my French was not equal to it!

Technical Developments.—It may have occurred to some of you that I have rather avoided technical matters. So I have—a fifty years' history of technical details would be somewhat indigestible. But I had better speak of a word or two.

(1) *Superposing.*—It is only a word, but what a vast work it represents to us now. How strange to us now looks the day of small things. In regard to this as in so much else our visitors are apt to say, "you have nothing much to learn from us."

These circuits, that we call "phantom" circuits—surely less prosaic folk would call them "fairy" circuits! I cannot tell you all we do with them. How we get a phantom circuit additional from two physical circuits, and it is a better circuit than either; how we bluff a telephone circuit into taking a telegraph circuit into itself although putting that same circuit beside it might cause it serious interruption; or how we combine a bit of a telegraph line with a bit of a single wire telephone circuit to improve the efficiency of the telephone circuit.

(2) *Loading.*—Is only another word, but it carries one into the fairy land of science where miracles are worked. The researches of Oliver Heaviside led the way. I remember his articles in the *Electrician* when the editor remarked that he was proud to have the articles in his columns because such work should be published, but probably few readers could follow its meaning! Then Pupin put Heaviside's mathematics into the form of coils with iron core, and we had "coil-loading"; and someone else, later on, stretched out the iron core and wound it round a copper conductor, and we had "continuous loading"; and now we know that we had to wait for many years for this because we had not the knowledge to read aright the mathematics of that long ago.

(3) *Balancing.*—This is another word of great import too. One that we are specially interested in because our own engineers have probably done as much as any to give it practical application.

It means that we so sort out and connect sections of the various pairs of wires in a cable, that we secure accurately balanced pairs over long distances, whereby loading and superposing can be made supremely beneficial.

(4) *Telephone Repeaters.*—When in 1893 I wrote in the *Manual of Telephony* that a fortune awaited the inventor of an efficient telephone repeater, I neither thought we were within sight of a solution nor did I realise that the "fortune" would be so divided between a multitude of workers that it would only accrue to the art and not to the individual. Yet so it is. The so-called Thermionic Valve first used for Radiographic work has now been developed to meet the far more exacting requirements of the duties of a telephone repeater. This is a true repeater; that is to say, its introduction does increase the efficiency of speech to the limit of the worst sections of the line, so that the shorter the section the better the speech. In fact the "valve" is also an "amplifier"—it is capable of magnifying the incoming energy as much as 1,000 times. It has been stated that the Admiralty, in order to pick up certain buzzer signals between German ships, employed as many as 19 thermionic amplifiers in cascade—a magnification of about a million times.

For ourselves we were among the first to hail its advent and to take advantage of it.

We have applied it to telegraph circuits. For example, the speed of our £250,000 war cable to Russia was increased by 60 per cent. by the application of valves. Our new underground cables to the north of Britain (although meant for far greater distances) will consist of conductors only one-fifth the weight of those laid in 1913; and only one-tenth the weight of the aerial wires erected for the same purpose twenty years ago, when, with the completion of a most carefully-planned cable on the best known lines, we had just proved it impossible to telephone underground to Birmingham. All by means of what looks like a rather curious incandescent lamp.

We have nine Telephone Repeater Stations already working and others "under weigh," several of which will be specially built on selected sites.

Miscellaneous.—*Storms and Lightning.*—The periodical occurrence of severe storms has blazed the course of the history of open telegraph wires with disaster. Hitherto, not only has regard for economy prevented the obvious adoption to an all-underground system, but the efficiency of the service was dead against it. Now that loading and balancing and thermionic valves are with us, and there is a progressive reduction in the cost of underground work, no doubt in due course—and building of hundreds of miles of cable route takes a considerable amount of time—we shall be less dependent upon absence of storms for continuity of our communications.

(2) A great storm which swept the country in 1876 definitely shaped the policy towards construction of underground circuits. At that time we had over 8,000 miles of wire underground as compared with 1,928 miles in 1870.

(3) Old telegraphers remember still the snowstorm of Dec. 26, 1886. It bore the "record" of its time. It swept the whole countryside and left London with only 7 circuits to the provinces.

No doubt this storm greatly accelerated the policy of extending the underground system, and the next year shows that of the 1,745 circuits to the C.T.O., not one passed over London—every one came in underground.

(4) Snow storms and gales in Feb., 1900, cost £13,000 to repair. It is remarkable that the Postmaster-General awarded a gratuity of one day's pay to all workmen of the Engineering Department who were employed in restoring communications.

(5) At the end of March, 1916, a most severe gale, accompanied by snow and freezing rain swept across the whole country from the north-east. It left a belt of devastation. Over 41,500 poles had to be re-erected, more than 17,000 miles of copper wire had to be issued to replace that thrown down. The cost of repair was at least £350,000.

(6) *Lightning.*—Little more than 20 years ago the occurrence of a storm accompanied by lightning was virtually a signal for the practical cessation of all operating of a telephone exchange, owing to the nervousness of the operators. We realised that with our wide-flung Trunk system that would be insupportable, and we set ourselves systematically to inspire the confidence of the staff by adoption of every possible precaution. And we succeeded.

Personal tribute.—Amongst the figures which outstand in the memories of the older engineers is Harry R. Kempe. Everyone knew his technical ability; many recognised his great mechanical ingenuity; and I fancy that an unusually large circle delighted in his genial personality. I wish that I could have given more than a paragraph to some of his contrivances. I have already referred to the Sounder Silencer. The Water level Apparatus was also his, and one of the prettiest of mechanical contrivances—the electrically-driven quarter-minute clock—was also due to him (1898).

Staff.—At the transfer the Government determined to continue the practice of the companies and to work the telegraphs by women as well as by men. In these days we are used to the idea, but it was a distinct experiment in 1870. In 1871 and in 1914, the number employed were:—

	1871	1914-15
Men	2,035	191,032
Women	479	62,718
	2,514	253,750

The earlier figures, of course, represent telegraph operators almost entirely, but the figures for the year before the War relate to all classes in Post Office service.

Technical Education and Instructions.—It has not been possible to refer to the encouragement of technical efficiency that has been systematically extended to the staff, and as systematically responded to. Nor can anything more than reference be made to the printed technical literature that has been issued; from the first modest paper of June, 1870, on "Technical Terms,"

Digitized by Google

to the pamphlet issued this month with the same title as one of a series of "Technical Pamphlets for Workmen," the production of which series was initiated by the present Engineer-in-Chief last year, and of which nearly sixty of the series have already been issued.

It must suffice, too, only to mention the foundation by the Department of the Institution of Post Office Electrical Engineers (whose publications have a world-wide circulation) and of our own Telegraph and Telephone Society, continued from the corresponding organisation of the late N.T. Co.

Suggestion.—I wonder whether a mere engineer may venture on a constructive administrative suggestion.

When Parliament decreed the birth of Postal Telegraphs, the total number of employees of the Post Office was 28,429, and the Telegraph employees to be added numbered 2,514, making a total of 30,943. To-day the Postmaster-General, through the Secretary, rules an army of about a quarter of a million men and women.

His business includes :—

i. Collection and delivery of :—		
Letters, &c.	5,800	millions
Parcels	132	,,
ii. Savings Bank with—		
Depositors ... ... over	9	,,
Deposits ... ... ,,	23	,,
Amounting to ... ... ,,	£51	,,
Withdrawals ... ... ,,	11	,,
Amounting to ... ... ,,	£50	,,
Annual Interest payable ... ... ,,	£4¼	,,
Total Deposits ... ... ,,	£187	,,
iii. Money Orders and Postal Orders, about 175 million transactions ... ... of value	£120	,,
iv. Telegraphs with receipts ... ... over	£3	,,
v. Telephones with receipts ... ... over (1914 figures are used).	£6½	,,

It seems to me questionable whether Parliament can reasonably pretend to hold a single Minister responsible for this vast concern ; and that there would probably be a clear advantage in having one Minister of Posts and another of Telegraphs. It is scarcely to be expected that the head of the present department can obtain such a grip upon the enormously technical system of telegraphs and telephones as to be in a position of effectual control.

Of course, there would be no need to separate public telegraph from postal business, but the respective charges could be settled, as presumably such charges are settled, in respect of the enormous work now done by the Post Office in payment of old age pensions and other matters which I have not included above.

War.—(1) *South Africa.*—In many ways, the War in South Africa (1900-01) was a blessing in disguise—it helped us to understand some of the difficulties of real war. How ludicrous it seems now to read that 210 men of the Engineering Department served in South Africa, and that important works suffered in consequence. All but 13 (including 7 R.E.'s) who died in South Africa, were back in 1902.

(2) *The War.*—(*a*) The Post Office Telegraphs were in the War from the first moment—the five German cables from Borkum to Brest, Vigo, Teneriffe and Fayal being cut by our cable ship in the early morning of Aug. 5, 1914.

(*b*) Throughout the War the cable repairs required of the Post Office Submarine Department numbered no less than 285.

(*c*) In September, 1915, the *Monarch* struck a mine off Folkestone and sank with the loss of three lives. She was replaced a year later by the new *Monarch* at a cost of £65,000.

(*d*) A total of over 114,000 emergency works were carried out for the Naval, Military and Civil authorities during the War. Some were of very great magnitude, such, for instance, as the Telephone Exchange at the Hotel Cecil, with 41 Operators' positions and 2,000 lines, plus 300 junctions. It was ready for service in eight weeks from the time of receipt of the order.

(*e*) Major Purves' work in charge of designs, to meet the needs of the armies, is fairly well known. Under his direction, about 200 items of special apparatus were designed ; contracts exceeding a million pounds in value were placed for such items ; and the designs produced are now the accepted standards.

(*f*) To Mr. Sinnott was due the design of some of the military cables, including the novel device of enamelled copper wire, gutta-percha covered. This, at a later date, but during the War, was patented in the British Patent Office, by a citizen of Berlin !

We supplied, of various types of trench and field cable, nearly 45,000 miles, with a wire mileage of about 200,000 miles.

(*g*) The Post Office purchased, examined, tested and supplied to the Military Authorities, stores to the total value of nearly 9½ million pounds.

(*h*) When War was declared, the Post Office became responsible for withdrawal of all wireless apparatus –there were 2,916 licenced stations, and 800 unlicenced. We erected 22 detecting stations for the tracing of illicit signalling, and in other ways the services of our skilled Radio Engineers wer utilized by the Forces of the Crown.

(*j*) The help rendered by our very restricted Research Section was quite considerable. Mr. Pollock's assistants produced about 23,000 sound-ranging microphones, which G.H.Q. officially reported had located over 80 per cent of all the enemy gun positions at the front.

(*k*) These are only a few of the ways in which the Engineers of the Post Office helped War work. Other departments did their share also, and the War work of the British Post Office would form a really entrancing story for some Post Office man to take in hand.

(*l*) The effect of the War upon development of our ordinary system may be illustrated by the following figures of overhead trunk circuits during the last six years.

	Miles of Wire.	*Number of Poles.*
1914-15 ...	22,040	17,200
1915-16 ...	12,000	7,100
1916-17 ...	844	353
1917-18 ...	783	543
1918-19 ...	215	218
1919-20 ...	6,400	4,300

(*m*) Damage to telegraphs by air raids and bombardment from the sea cost the department about £11,000.

(*n*) Our contribution of men was of a much more serious character.

Staff of all grades released from the Engineering Department (exclu ling 106 members of K Telegraph Co. of R.E.) numbered 12,877—about 51 per cent. of the total employed immediately prior to the outbreak of War. Of these, 942 lost their lives while on active service. The Post Office as a whole, sent about 85,000, including 700 or 800 women ; and a total of 8,870 lost their lives.

(*o*) The War found the telephone system under Government control, and the fact was of inestimable value to the Nation. The United States Government had to take charge of the telephone service there during the two years of its participation in the War. Our five years of war did not disorganise our service more seriously than the U.S.A.'s two years did their numerous organisations.

Insurrection in Ireland, 1916.—Insurrection seems a condition so foreign to our experience that one must just refer to the Sinn Fein Insurrection in Dublin at Easter, 1916. The resource and initiative of the Post Office Engineers went a long way towards saving the situation, as they secured communications with London and obtained military protection for the vital telephone communications.

Conclusion —In making a review of the work, one is constantly impressed with the feeling that never a chance is missed by the Post Office busy bees to improve the shining hour. At one time you will find them designing a new submarine cable, with a view to better communication with the Comtinent. Then, when there is no new cable to be laid, they must needs carry on an exhaustive series of experiments to ascertain what distant provincial town can get through by telephone to Belgium or what distant places in France can speak efficiently to London.

In presenting this address, Ladies and Gentlemen, I have sought to deal with the subject with a due regard for historic proportion ; I have prepared an "Apology for State Telegraphs" in the old ecclesiastical schoolman's sense —a statement of the considered facts of the case *for*. When I commenced my work I had a feeling that at some stages it might be reasonable to be apologetic; to admit that at this stage or at that, private ownership of the system might have given better results ; but I submit, that with such a record of consistent and substantial progress, there is no reason to be apologetic ; that with such a record, it may justly be held that the wisdom of the decision arrived at 50 years ago has been amply justified by the results.

I would also venture to suggest that, altogether apart from such justification, present-day criticism of a Government Telegraph and Telephone System as such, borders on the ridiculous ; that if the Government announced an intention to transfer its telephone business to a private syndicate, there would be a howl of protest, even from the critics themselves.

The system is not perfect. It has grave defects, as well as minor blemishes. Like many another, I have spent a lifetime in developing small improvements and removing blemishes. More able men have dealt similarly with bigger matters, and are still concentrating skill and experience of inestimable value to the perfecting of a great ideal. Such work is work to rejoice over and be proud of, but criticism, the only logical outcome of success in which would be denationalisation, can only be thought of as folly.

I must apologise for the inordinate length of this communication, which, even so, has quite woefully failed to give an adequate account of the subject.

THE BAUDOT.—XVI.

By J. J. T.

FIG. XLV gives two sketches of selector levers showing their curious shape, the washered axles *a* also the feet *f* which trail into the slots of either T or T¹. Each selector lever has its own particular position in relation to the combiner wheel. They are not interchangeable, being carefully ground down to fit with special exactitude.

Fig. XLVI gives another photographic view of the combiner wheel with its gearing R, selecting disc V and cams K and K¹, the *rest* and *working* tracks T and T¹, printing wheel V¹ and type-wheel W. The two latter, as already mentioned, are fitted to the

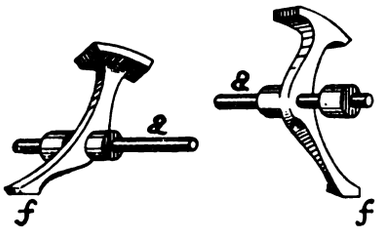

FIG. XLV.

axle X by an extension X¹ which extends beyond the receiver casing. X carries a cam, K¹, the cam itself being adjustable on X by means of a fixing screw L shown in the photo on the under side of the axle.

Bearing in mind the position of V¹ and W *outside* the receiver casing, we continue our study of the sequence of levers, &c., and their movements consequent upon the jerking upward of the sixth lever C⁶, Figs. XLII, XLVI and XLVIII. *Owing to a failure of the type in some of the impressions of the last issue of the* T. & T. JOURNAL, *this lever was incorrectly described as* C *instead of* C⁶ *in the text*, p. 29, par. 2.

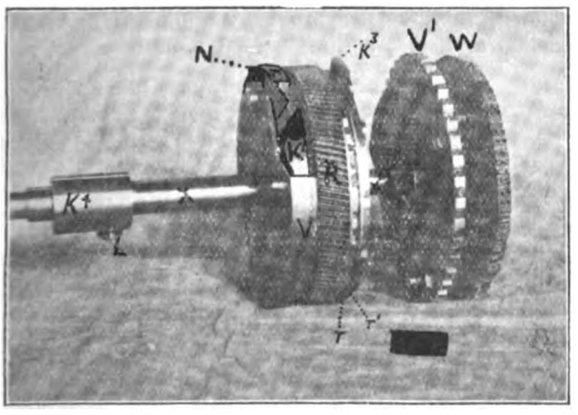

FIG. XLVI.

Upon an extended axle of C⁶ is rigidly fixed the "propulsion" lever OO¹ (Figs. XLVII and XLVIII) and into this lever is embedded one end of the "finely tempered steel spring" already mentioned. The free end of this spring passes underneath the end of an adjustable tension screw B (Fig. XLVIII). To the free end of OO¹ is fitted a crank K, which carries the propelling rod R, the lower end of which is screwed into a second crank K¹. The length of R may be slightly modified by means of its screw-ends which fit into KK¹., K¹ carries a short arm f which bears P known as the pedal. This pedal fits on to the front of the receiver casing and its free end terminates in a hammer-head H. A click C pivoted at e presents its lower end *d* to the under surface of the hammer-head H, support being given to *d* by the flat spring F. The retaining end of C holds Ca, the printing cam, in position when no printing is taking

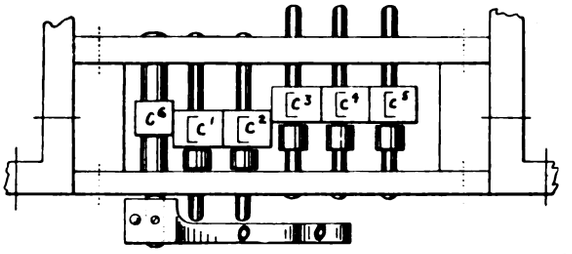

FIG. XLVII.

place. The sequence of movement is therefore as follows:—When C⁶ is thrown slightly backwards by the rejection of the selector levers the motion is imparted to OO¹ which draws the rod R up with it; the arm *f* carried in the same direction, throws the hammer-head H of the pedal P on to *d* which being pressed down-

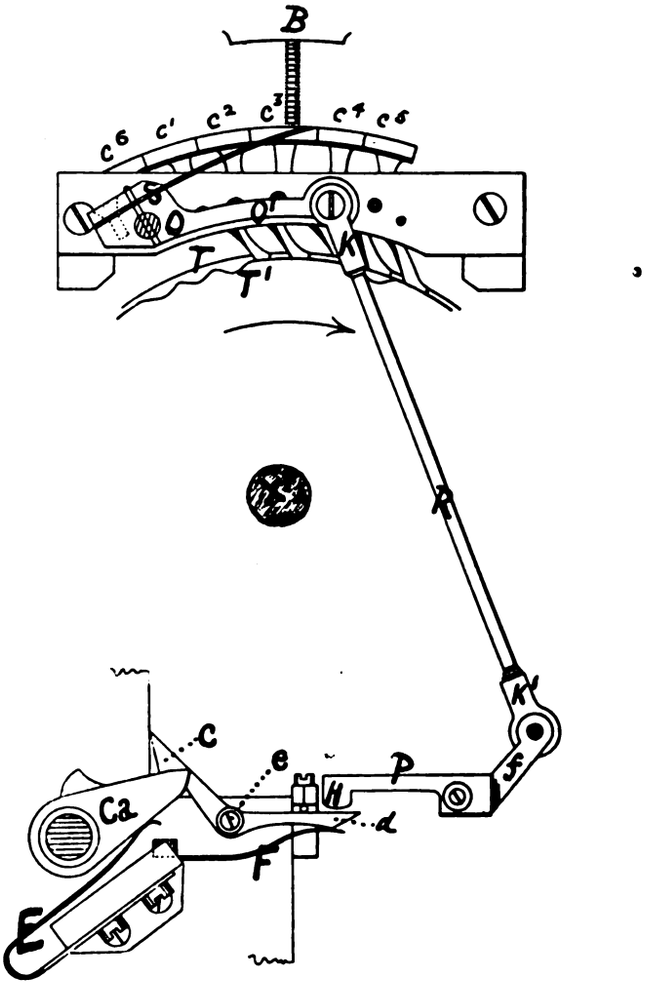

FIG. XLVIII.

wards draws back the retaining end of the click C which thus releases the printing cam Ca. This latter, impelled by a strong steel spring E, flies upward, its nose engaging with the teeth of the printing wheel V¹ (Fig. XLVI) which rotates just above it upon the axle X¹ (Fig. XLVIII).

(To be continued.)

THE TELEPHONIC DEVELOPMENT OF THE WORLD AT DEC. 31, 1919.

BY W. H. GUNSTON.

DESPITE four years of War in which all the larger telephone-owning countries (except Sweden) were engaged, the total number of telephones in the world has increased from about 14,500,000 in 1913 to 19,370,000 in 1919. In Europe the increase is from 3,950,000 to 4,880,000.

These figures are based on recent official information except in the case of a few countries which are not in a position to supply data. In these cases, as explained in the following notes, recourse has been had to estimates computed from the latest obtainable figure. Information respecting some of the extra-European States, whose telephonic development is in the hands of several telephone companies, is difficult to obtain, and estimates have been resorted to in these cases also.

EUROPE.

The total number of telephones in Europe is approximately 4,880,000, giving a ratio 1 telephone to 82 inhabitants. This proportion would be much better if Russia, Spain and the Balkans were excluded. It is a remarkable fact that within a boundary embracing Sweden, Norway, Denmark, Germany, Austria, Switzerland, Holland, Belgium and Great Britain, are included 3,870,000 of the 4,880,000 telephones in Europe, giving a ratio of 1 telephone to every 35 inhabitants. The Latin countries account for only about 610,000 of the total number of telephones, and other States for about 400,000. Whether the striking difference in the development of the Latin States and those which are mainly Teutonic either by race or speech is due to language, temperament or latitude is a problem of which there is no obvious solution.

Austria, which had 160,000 telephones in 1913 has now, after the loss of Bohemia, Carniola and the Coast Provinces, 114,075. Vienna has 79,858 telephones, and Graz 4,257.

Belgium had 54,691 lines in 1914, but most of these were dismantled during the German occupation. The system is so far re-established that there are now 30,383 lines, which converted to stations should represent about 38,000. There are 10,813 lines in Brussels and 5,348 in Antwerp.

Bulgaria.—No recent information is obtainable. This country had 4,378 telephones in 1915.

Czecho-Slovakia.—No information obtainable. On the basis of the development of Bohemia, Moravia, &c., before the War, it is estimated that there are 54,000 telephones in this country. Prague had well over 10,000 stations before the War.

Denmark.—The number of stations is given as 207,130, but this is probably the number of lines, as there were 219,460 stations in 1918 and the progress in Denmark is steady. The number of stations should be about 238,000, of which 85,363 are in Copenhagen.

Esthonia has 1,896 stations, of which 863 are in Tallinn (Reval).

Finland.—No information has been received since 1911, when there were 35,000 stations in this country. As there is no clue to the rate of development no further estimate has been attempted.

France, which had 328,000 telephones in 1913, has now 399,519, inclusive of those in Alsace-Lorraine. Paris has 149,050 stations; Marseilles 10,891, and Lyons 9,780.

Germany, despite the loss of its Polish provinces, Alsace-Lorraine and other territory, has increased since 1913 from 1,302,607 to 1,767,156 stations. Berlin has 187,982; Hamburg 80,697; Munich 41,504; Leipzig 37,732; Frankfurt 35,003; Cologne 33,764; and Dresden 32,006; while altogether 21 cities have over 10,000 stations.

Great Britain has increased from 774,300 in 1913 to 911,937. London has 311,350 stations; Glasgow 40,936; Liverpool 38,493; Manchester 37,748; Birmingham 24,528; and Edinburgh 17,224. Twelve cities in all have over 10,000 telephones each.

Greece.—No information has been received respecting this country, which had 1,967 telephones in 1912.

Hungary.—It is difficult to estimate the number of telephones in this country, which is not yet in a position to furnish statistics. Allowing for loss of territory, there should be about 60,000 telephones within the present limits of the Republic. Budapest had over 20,000 stations before the War.

Iceland had in 1919 2,033 stations, of which 998 were in Reykjavik.

Italy.—The number of telephones in 1919 (99,637) shows an actual decrease compared with 1918 (115,668). This is attributed "to the invasion of Venezia and the necessities of War." Milan has 15,331 stations, and Rome 13,425.

Jugo-Slavia.—No recent information is obtainable, nor has any estimate been attempted. The few thousand telephones in this State would make little difference to the total for Europe.

Luxemburg has 5,190 telephones, of which 2,236 are in the town of Luxemburg.

Netherlands.—Information for 1919 is not yet available. There were, however, 134,507 telephones in this country in 1918, and at the usual rate of development there should be about 142,000 now. Amsterdam has 20,211 telephones, and the Hague and Rotterdam each over 10,000.

Norway also has not furnished figures for 1919. It had 122,699 in 1918, and should have about 133,000 now.

Poland.—The total number of telephones is 36,169, of which 22,400 are in Warsaw. This points to an extraordinary destruction of the system during the last few years. In 1915 there were 37,000 telephones in Warsaw and Lodz alone, to say nothing of the rest of Poland, Posen, Galicia, &c.

Portugal.—The Anglo-Portuguese Telephone Company has 12,836 stations, and there are probably about 2,000 on the State system. Lisbon and district has 9,413 telephones.

Rumania.—No recent information available. Rumania had 20,000 stations in 1914 and has since had a large accession of territory. On the other hand, it must have suffered considerably from the War.

Russia.—No information is procurable from Russia, and any estimate of its total number of telephones must necessarily be uncertain. There were 324,500 telephones in the Empire in 1915, but after deducting those in Poland and the Baltic States, about 250,000 would remain. Allowing for a decrease of 50,000 owing to unsettled conditions, 200,000 might approximate the present total in Russia, Lithuania and the Ukraine.

Spain.—Information for 1919 is not yet available. There were 57,391 telephones in 1917, and at the usual rate of increase the present total might be 75,000.

Sweden.—The number of telephones has increased from 234,089 in 1913 to 388,794 in 1919. Stockholm has 126,961, Gothenburg 21,850, and Malmö 11,227.

Switzerland.—There were 96,624 stations in 1913 and there are 138,843 now. Zurich has nearly 20,000 stations, and Geneva and Basle over 10,000.

Turkey.—The Constantinople Telephone Company had 5,820 stations in April, 1919, and 6,078 in April, 1920.

† The population figures are based on the latest Censuses, the dates of which vary between 1910 and 1916. Those for France and the other States with altered boundaries are estimates for the years 1918 and 1919.
* Estimated. See foregoing notes.

ASIA.

The feature of the telephonic development of Asia is that the further East one goes the more telephones one finds. Japan has over 309,000; China and Hong Kong about 33,000; Dutch Indies, 32,000 and India, 30,000; whilst in Persia, Arabia and Turkey in Asia the telephone is practically non-existent.

The figures for Japan are official, whilst those for China are based on an American estimate of 27,000 for 1914. This has not been increased, as it appears to be already sufficiently liberal. An official statement shows that there were 14,112 telephones in China in 1912.

India has 10,797 stations on the Government system and 19,225 on the systems of various companies. There are 7,429 telephones in Calcutta and 7,153 in Bombay.

In the *Dutch East Indies* there are 28,984 State telephones, and about 3,000 more on companies' systems; 7,060 of these are in Batavia, and 4,850 in Soerabaja.

The ratio of inhabitants to telephones has not been worked out in the case of Asia and Africa, where the proportion of telephones to vast millions would be of little significance.

REVIEWS.

"Telegraphy." By T. E. Herbert, A.M.I.E.C. Sir Isaac Pitman & Sons, Ltd., Parker Street, Kingsway, W.C.2. 18s. nett.— This is the fourth edition of a book first published in 1906, which has been brought up-to-date by the author, a Post Office Engineer, with the aid of his colleagues who are specialists in their particular branches of the art. The treatise, which rightly professes to be a detailed exposition of the Telegraph system of the British Post Office, is recommended by the examiners of the City and Guilds of London Institute Examinations in Telegraphy. It contains over 600 useful diagrams and illustrations and over 1,000 pages. It is a useful compendium of information on the subject, as evidenced by the many editions and reprints which have been disposed of since 1906.

WESTERN DISTRICT CONTRACT OFFICE.

THE second annual dinner of the Western District Contract Office took place on Wednesday, Nov. 17, at the Dean Hotel, Oxford Street, W.1.

The Chair was taken by Mr. W. V. Pegden, the District Contract Agent, who was supported by Major G. F. Preston, C.B.E., the Controller, L.T.S.; and Messrs. W. A. Valentine, Deputy Controller; J. Stirling and J. F. Edmonds, Assistant Controllers; W. F. Taylor, Superintendent of Contracts; W. R. Bold, Superintendent of Accounts; P. T. Wood, A. J. Sharpley and F. J. Phillips, London Engineering District.

The programme consisted of the usual toasts, interspersed with vocal and instrumental items contributed by the following members of the staff—Messrs. Horlock, Barnard, Child, Swain, Bradshaw, with Mr. H. Neil at the piano.

Mr. W. F. Taylor, in proposing the toast of the Western District Contract Office, compared himself with a nervous divinity student who had to preach on the subject of Zacchaeus. He commenced thus: My friends, Zacchaeus and I have many similar points. Zacchaeus was a small man; so am I. Zacchaeus was up a tree; so am I. Zacchaeus came down again; so will I. Mr. Taylor gave figures of the great progress made by the Western Contract Office, the largest in the country. Mr. W. V. Pegden, in replying, spoke of the loyal co-operation of the staff which had worked with him during seven years. Mr. P. T. Wood, in proposing the toast of the London Telephone Service, referred to the abatement of the Press campaign. Mr. G. F. Preston, the Controller, responded, and was moved by the anecdote of Zacchaeus to tell of a speaker at a Church congress who said that all sermons should be like a lady's dress—long enough to be decent and short enough to be interesting. Referring to newspaper criticism, Mr. Preston said that he did not object to jokes, but he did ask that criticism should be of a fair character. Mr. W. A. Valentine replied to the toast of "The Visitors," and remarked on the good effect of such gatherings in bringing colleagues together. He mentioned that the London Telephone Service was sending through on an average 1,300,000 calls a day. Mr. J. F. Stirling proposed the toast of the Chairman, and expressed his admiration for District Contract Agents generally and their way of getting things done. The speeches concluded with Mr. Pegden's response.

THE TELEPHONES.

A series of prominent special articles appeared in *The Times* attacking the Post Office management of telephones. It was followed by a series, contributed by a Post Office engineer in defence of the Department—published unfortunately after considerable delay, in smaller print. A rejoinder followed this second series, finding itself also in the larger print and on the prominent page. To this rejoinder a reply was sent and it appeared as a letter to the Editor, but with the omission of the portion, indicated in brackets [, which follows the first paragraph.

I had not intended to make any further demand on your space in defence of the Post Office management of the telephone system, but I hope you will allow me to call the attention of your readers to an article on long distance telephony in your issue of the 14th inst. which, with your editorial comments thereon, is calculated to mislead. The article deals with the notable results which have followed the invention of the thermionic valve, and its adaptation for use as a telephone relay, and, in its announcement as a great and new American solution of the problem of long-distance telephony, it is easy to recognise the well-known voice of the American propagandist, which has recently been allowed to echo from the excellent sounding board provided by the columns of *The Times*. Your editorial notice comments on the fact that this device "has *now* been applied to long-distance telephony by the Western Electric Company and goes on to say: "We hope that the General Post Office will display some of the celerity which we should expect from a commercial company in taking up a development promising economy and efficiency. But we have our doubts. State Control does not promote prompt adoption of novelties." It is good that your readers should be told of these "magical valves, with their invisible streams of regulated electrons," but it is a pity that the desire for another stick with which to thrash the Post Office should lead to the promulgation of the idea that the valves, and the telephone repeaters in connection with which they are used, are foreign products. To begin with, the "electric valve," as a master patent covering all subsequent developments, is due to the work of Professor Fleming of London University. In the application of valves to the long-sought solution of the problem of the telephone repeater, the British Post Office was as early in the field as any other body of workers. The first valves made in this country were constructed in the workshops of the Post Office Research Department. Their trial as telephone speech amplifiers was commenced in 1913, and, although the idea of immediate commercial development was extinguished when war broke out, research and construction were continued on a reduced scale, for want of staff, in view of their probable utility on military telephone circuits. Telephone repeaters using thermionic valves were subsequently manufactured and were fitted on military and other lines in this country, and supplied to the Army in France, where in many cases they did valuable service, enabling communication to be maintained in conditions which, without them, would have made it impossible. In those days, the possibility that the British Army might lose the Channel ports was always in mind. Had this unfortunately happened, and our Armies had to retire on Dieppe as a base, everything was in readiness to establish a number of telephone lines between London and Dieppe, using quite light copper conductors. Such a scheme was only made possible by the availability of the thermionic valve as a telephone repeater. The economies in line construction which could be effected by the use of telephone repeaters were foreseen by the Post Office from the commencement, and on the resumption of long distance telephone cable construction after the war, the whole of the new cables were designed for use in conjunction with such repeaters. Many of these are now approaching completion. A scheme for the provision of repeater stations on a very large scale throughout the country has been worked out, and buildings are in course of provision at several places. Some of these stations are among the largest projected by any telephone administration in the world. The effect is that whereas the existing long trunk cables contain conductors using 300 lbs. of copper to the mile, the new trunk cables have conductors weighing only 20 lbs. to the mile. The thermionic valves used in this country were developed entirely by co-operation between British manufacturers and Post Office engineers, and the telephone repeater system, as in use here at the present time, was developed entirely by the Post Office. This was mentioned in my previous article in *The Times*. It is common knowledge in electrical circles, and has been the subject of many lectures and communications to the technical press by Post Office Engineers. Even your critical special correspondent, in the "rejoinder" to my article, states that "the Post Office has taken up the valve with enthusiasm and it is a good sign," although it apparently suits his purpose to ignore it now.

[Since I have mentioned this rejoinder, perhaps you will allow me space for a few words about it, as it is certainly not the practice of *The Times* to lend itself to the exaltation of foreign countries at the expense of England. Under the cheerful title of "Our Archaic Telephones," and with the large type heading "Official Reply Exposed," it proceeds to pour forth a further string of general statements and mis-statements, without dealing with a single one of the arguments which I had put before your readers. Your correspondent now says that the London to Liverpool trunk cable, completed in 1916, "did not talk for a year or two." There is not a shadow of foundation for this statement. The cable was brought into use for general purposes immediately on completion, and from that day to this there has not been an interruption of communication on a single one of the many circuits it contains. He says "it is a fact notorious to telephone engineers that the American Bell system has always been far ahead of the Post Office system in the use of telephone cables, both for local distribution and for trunk lines." The telephone engineers he refers to will be surprised to hear it! Here are a few figures which I happen to have by me:—

Associated Bell Co.'s (1917) percentage of underground conduit to total miles of telephone route	2.65	per cent.
British Post Office, local system (1917) percentage of underground conduit to total miles of telephone route	18.6	,,
Bell Co.'s long lines Dept. (1917) percentage of underground conduit to total miles of telephone route	2.3	,,
British Post Office, Trunk System (1917) percentage of underground conduit to total miles of telephone route	19.6	,,
Associated Bell Co.'s (1920) percentage of underground wire mileage to total wire mileage ...	60	,,
British Post Office (1920) percentage of underground wire mileage to total wire mileage	80	,,

In response to my claim that the British Post Office system includes a larger proportion of subscribers served by automatic telephone exchanges than that of any other administration, he retorts, somewhat obscurely, that it is easy for the Post Office to "dabble in automatics," whereas the Bell Co.'s have made a prolonged and careful study before embarking on the policy. My reply is that the Post Office also made a very careful study, the proof of which is that every automatic exchange installed in England has been an acknowledged success and has given obvious satisfaction to the subscribers. Can he say the same of America, where several automatic exchanges have failed to hold the field and have had to be taken out of service when they were comparatively new? His explanation of the reasons for the deterioration in the American service after the War is a somewhat amusing repetition of the considerations which I ventured to put forward in explanation of our own present short-comings. And he expresses them so emphatically as to suggest that anyone who would expect any other result must be ignorant of the effect of war conditions! Yet we are all well aware that the "jolt" which American industry received by the War was not one-tenth part as serious as that suffered by Britain. He sticks to his assertion that the American service to-day is much superior to ours. Yet, if your space allowed, I could produce a long string of testimony to the contrary, not only from statements in American newspapers, which he would contend are coloured by contrast with the very fine service they enjoyed before the War, but by the utterances of returned Britishers and of American visitors to this country, who

Digitized by Google

deliberately state that the present service in England is superior to that given in America.

I demolished the foundation of his story that the Post Office in the infancy of the telephone pronounced it to be a "scientific toy." He now "makes the Post Office a present of that story" and as a new catchword invents "the telephone a luxury" as an expression of the Post Office attitude. Believe me, this one is equally fantastic and nonsensical.

He says the supply of telephone facilities in Britain "will never catch up with the public demand. I do not believe it can be done." I could give you figures of the projected output of British manufacturers of telephone plant which would effectually refute this similarly fantastic statement.

I cannot, of course, compel his assent to the reasons I gave as contributory to the great development of the use of the telephone in America as compared with Britain, although it is easy to prove, and it has been proved, that the possible development in this country up to the present time, is not, and never has been, in the same ratio as the relative populations. On my parallel of the use of motor vehicles in the two countries, so fatal to his case, he makes no comment. He says "there are many square miles of houses in every big English city where a telephone, or perhaps two or more telephones, could be placed in every house." I hope that the future may prove him right in this, but if, at the present moment, he were to make a close inspection of two areas, one in England and one in America, what could he find? Fewer telephones in the English area undoubtedly. But he would also find a far greater proportion of the American houses equipped for central heating and for electric lighting. Many more of them would be fitted with electric cookers, electrically driven washing machines, knife cleaners, carpet cleaners, and other labour-saving devices. He would also find that the average income in recent years has been much higher in the American area that in the English one. There are, and must be, real causes for these differences, and the same causes have contributed largely to the difference in the degree of telephone development.

I suppose I must thank him for his tribute to the personnel of the Post Office Engineering Department, although it is clear that it is only expressed as a reason for further railing against the administration. The Post Office is not to be divided by patronage of a section. The Engineering Department is a part of the whole. It is loyal to the whole and it has reason to be so. It receives all the support it could wish for from the administrative "bureaucrats" both in finance and policy. Your correspondent makes the somewhat cryptic remark that the war "quenched the spirit of service in civil life" in America. Well, it has not done so here.

He claims for his statements the authority of 40 years' experience of telephone work. But antiquity in telephone matters is not in itself very impressive and the claim would carry more weight if he could show that he had ever been vested with technical or administrative responsibility. In his renewed attack he still harks back to the alleged sins of the Post Office thirty or forty years ago, and draws his main weapons from that era. Since then we have had a long succession of Postmasters-General in control, of all shades of political opinion and grades of experience. Is anyone nowadays really interested in this antideluvian standpoint? All I can say as a Post Office Official is that it does not interest me. I want to "cut the cackle and get on with the job."]

A POST OFFICE ENGINEER.

INDENTIFICATION BY ANALOGY.

Mr. Atkins, recently demobbed, wanted to get on to a friend at Ealing by 'phone, and on being asked to repeat the name of the exchange gave it in the approved Army style, thus: "E, for 'Erbert; A, wot 'orses eats; L, we're yer goes w'en ye're dead; I, fer ingin, them things in front of trains; N, wot lays eggs; G, for Gorblimey. 'Ave yer got it naow?'"

A CHRISTMAS FAIR.

ONE of the most notable and successful functions in the annals of the London Telephone Service took place during the month of December, when the staff held a Bazaar and Christmas Fair, the object being to secure the endowment of a bed in the South London Hospital for Women.

The idea was originally conceived by Miss Heap, who, in her capacity of Superintendent of the Female Exchange Staff, is well aware of the many cases of hospital treatment which inevitably arise among so large a staff, and of the difficulty which the South London Hospital experiences in adequately meeting the demands made upon its resources. The project, daringly ambitious though it seemed, was one which appealed to us all; even the men became demoralised, and devoted their leisure time to planning magnificent stalls and executing designs for the decoration and embellishment thereof; while the feminine members of the staff sewed furiously at blouses, &c., and knitted with such hearty goodwill that every infant in London must surely now be provided with a woollen coat and hat, and every mother a jumper!

Some there were who had experienced hospital treatment and worked for the sake of the institution itself, knowing its pressing need; and some—the older ones—recognised in the scheme a further opportunity; to them it offered a channel, however inarticulate, of expressing in a practical form devotion to a Chief whose example and ideals have been an inspiration to so many, and they counted it an honour to give their time and labour to the cause—but this is a digression.

The Bazaar, which was held at the Memorial Hall, Farringdon Street, was opened on the first day by Viscountess Cowdray and on the second by Mrs. Preston, and proved to be an unqualified success.

The Memorial Hall is not the easiest building in the world to transform into a place of light and colour and beauty; there is a certain air of gloomy dignity about it which repels all such attempts; it takes itself very seriously in fact; and yet, when the stalls had been erected and dressed with their beautiful merchandise, when the Christmas Tree had reared its glittering head upon the platform, and the "Lavender Ladies" with their dainty gowns and sweet-smelling wares tripped in and out of the crowd; when the solemn looking galleries had been draped with flags and the wonderful sweet-stall, disguised as a cottage complete with red roof and cat balanced perilously on tiles, had been installed in the centre of the Great Hall, the architect himself would scarce have recognised his handiwork.

And we all enjoyed ourselves amazingly! August gentlemen whose exalted rank causes us in normal times to utter their names in tones of reverence and awe, recklessly bought books and beads, cushions and caramels, dolls and d'oyleys with the utmost impartiality and goodwill, and cheerfully expended limitless sixpences on raffles for articles, the ultimate possession of which was bound to cause them the greatest embarrassment and responsibility during the journey home. There were many doctors there, too, women who had laboured all the day to relieve suffering humanity sacrificing their precious leisure to wish us well at the outset, and then—because they *are* women and the staffs were alluring—remained to buy as enthusiastically as the rest of us.

Refreshments were served in the Library by chintz-clad maidens and were worthy of all praise, and the professional manner in which these amateur waitresses discharged their orders and collected their tips was the envy and admiration of all beholders. The side shows, too, were a source of endless attraction; three fortune tellers were kept fully occupied, mystics who cast one's horoscope, disentangled one's love affairs and promised innumerable letters from abroad all for the sum of one shilling. There were concerts also and dramatic entertainments, and, last but not least, a lucky tub, which had every appearance of being inexhaustible, yielded intriguing parcels to eager hands with all the fascination of its kind.

We are proud to record the fact that royal interest was evinced in the affair, for Her Majesty the Queen graciously presented a picture which realised £93, and the Princess Mary also sent a large parcel of gifts, the sale of which brought in a further considerable sum. The total result exceeded our wildest hopes, for, at the close of the second day the momentous announcement was made that the Bazaar had achieved its object; as the result of the voluntary efforts of the workers the sum of two thousand guineas had been raised and the staff of the London Telephone Service will thus have the privilege of endowing not one but two beds in the South London Hospital for Women for all time.

E. B.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. JANUARY, 1921. No. 70.

AUTOMATIC DEVELOPMENT.

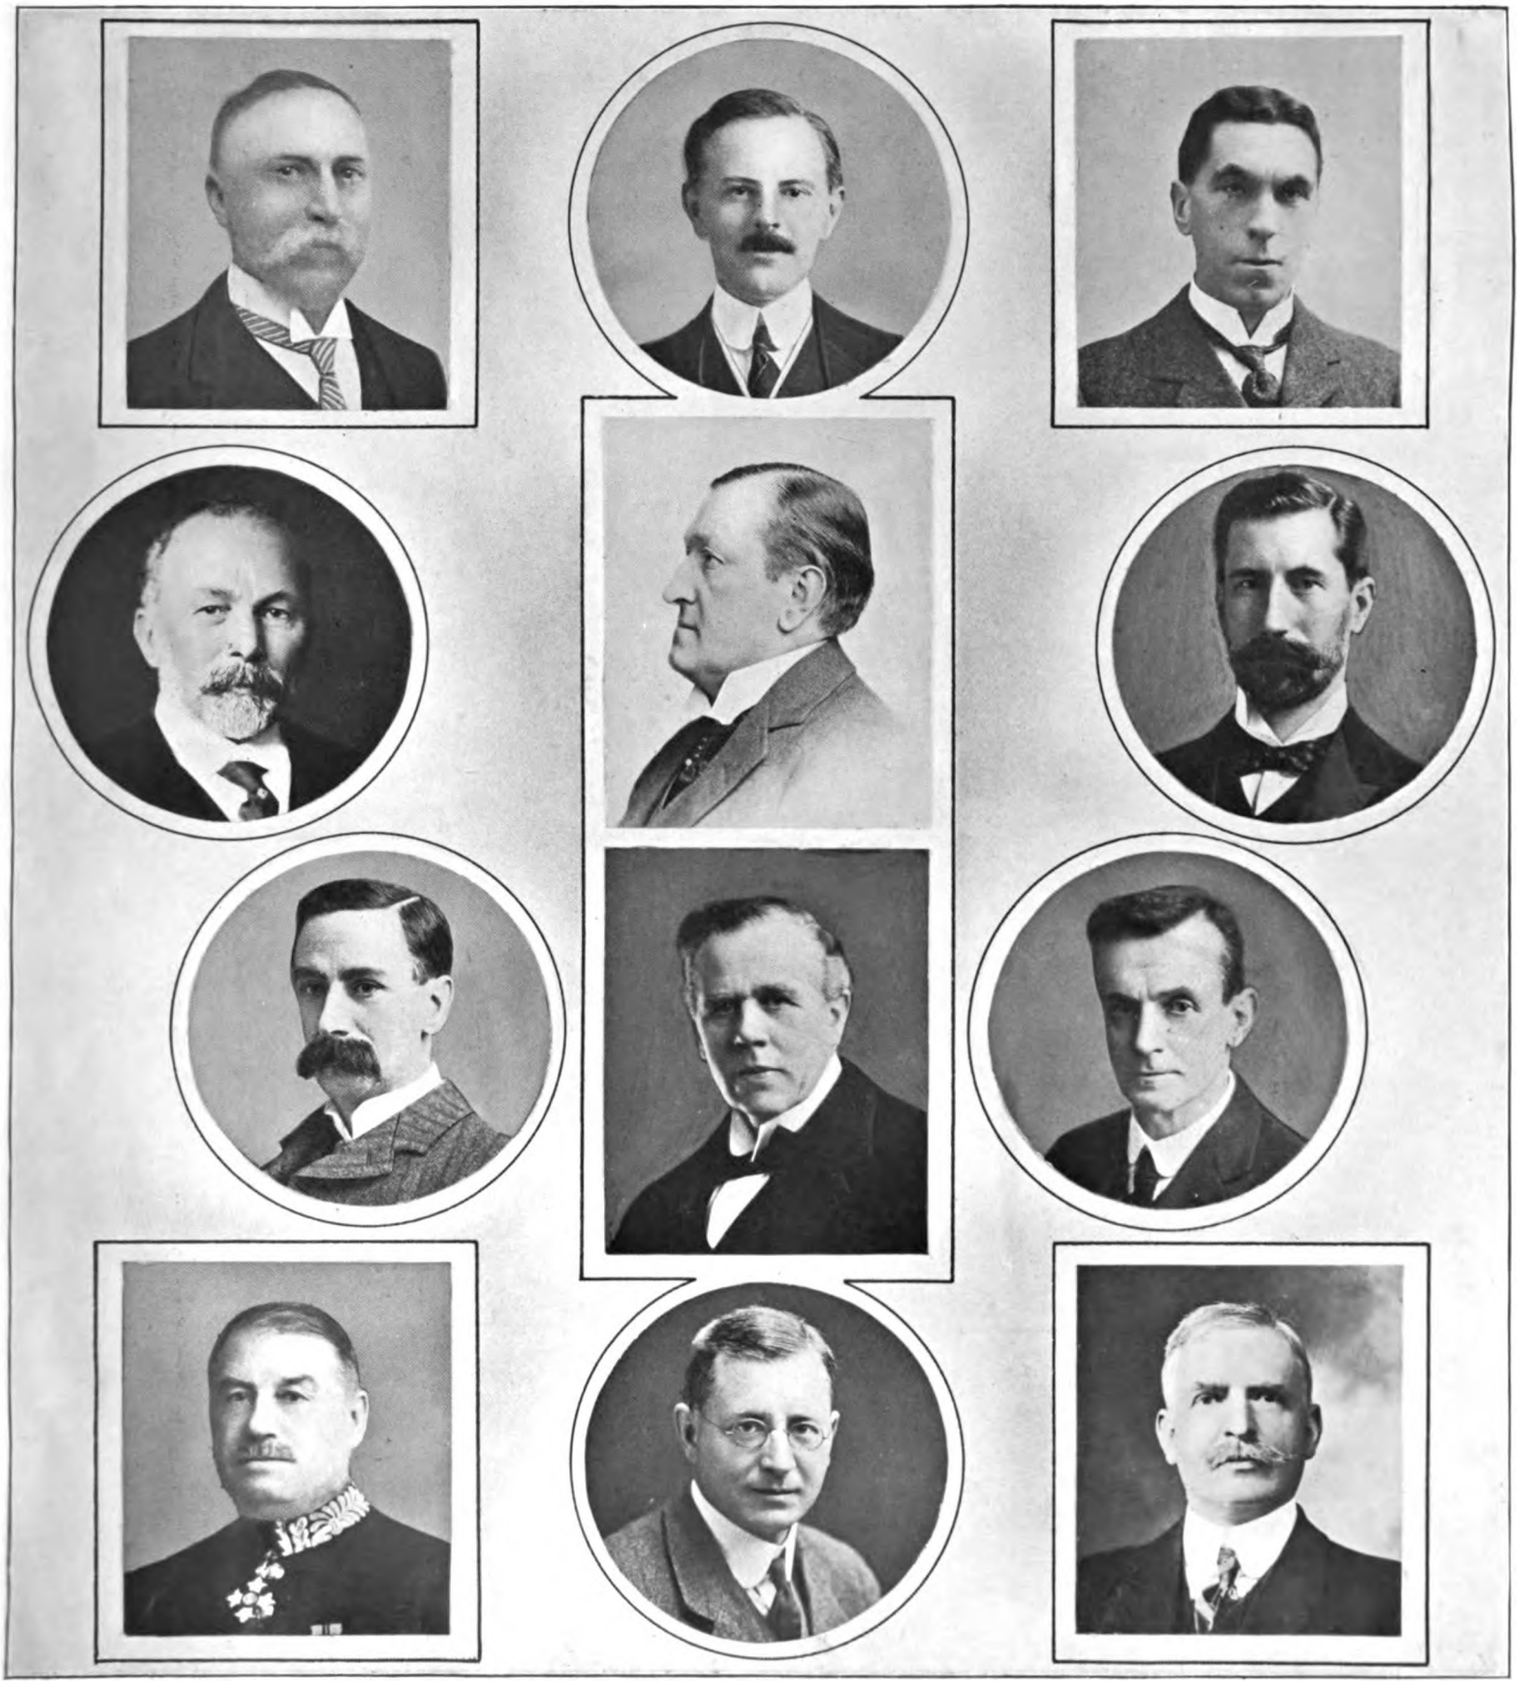
WE have referred before to the vague ideas which are current in the Press regarding the relative development of automatic telephony in this country and abroad. We have no desire to underestimate the great progress which this system has made, nor the still greater part which it will undoubtedly play in the future of telephony. Important developments are, as our readers know, about to take place in London; and New York, we understand, has definitely decided on an automatic system. These, however, will be its first appearances in cities with upwards of a million inhabitants, except Chicago, where the automatic system was—and is not. In fact the cities with over 100,000 inhabitants which possess automatic telephones do not number much above a dozen. Whilst we admit that automatic telephony flourishes in numerous medium-sized cities in America and elsewhere, we rather object to the frequent assumption of newspaper writers that it is well established in every country but our own. We are told that this or that country has "adopted" it, the impression conveyed being that the manual system is about to be abolished in the country in question, when the fact generally is that the automatic system is being introduced into one or two provincial exchanges.

Now we have *Electricity* complaining that the Post Office has dallied with the question until it is too late. "Colonial and foreign administrations have made up their minds long ago, and huge developments are in progress in various parts of the world." Huge developments are in progress, and this country is bearing part in them. Having "made up their minds," these administrations proceed to instal automatic exchanges here and there—France at Orleans and Nice, Australia at Sydney, Geelong, Malvern and Brighton, and Canada in several small cities, while New Zealand is installing four exchanges with between 1,000 and 2,000 lines.

But no country outside America has a greater number of automatic exchanges than this country, and even in the United States there are only about 400,000 stations out of 12,668,000 connected with such exchanges—a proportion of 1 to 32. This 40,000 represents telephones "ordered to date" at the end of 1919; it is by no means certain they are all installed. Moreover, the bulk of these telephones are installed by separate companies in separate towns, and not by the policy of any one great administration. It is further to be noted that while the largest American system, Los Angeles, has (or will have) 34,670 stations, the total number of stations in that city is probably well over 130,000, just as in Sydney (the largest automatic exchange outside America) there are 26,500 automatic stations out of a total of 55,000. In fact all the larger automatic exchanges in the United States serve only a portion of the system of the town in which they are installed, while the systems in Leeds, Portsmouth and other British towns are wholly automatic. In this country about one exchange station in 31 is served by an automatic exchange. *Electricity* says: "There are many full automatic exchanges in the U.S.A. besides which Leeds, our present largest effort, would be dwarfed." The American telephone system dwarfs our own in many respects, but it will be seen that the proportionate difference between the two countries in automatic development is slightly in favour of Great Britain; and it would not surprise us if Leeds alone had as many automatic stations as there are connected with all the European full automatic exchanges put together.

HIC ET UBIQUE.

THE *Electrical Review* points out that Johannesburg has 13,130 telephones, or one for every 11 white inhabitants, as against 1 to 25 in London. We have never attempted to compute the black population of London in connexion with telephone statistics and doubt if the effort would repay the trouble. But the comparison of the two towns seems to us uninstructive. The reason the black population is excluded from the Johannesburg calculation is presumably that they are not and are never likely to be telephone users. There are many in London who are not and are never likely to be telephone users and their exclusion from the figures of population would very materially improve the ratio of inhabitants to telephones.



———

The Electrician has the following two paragraphs:—

Telephone Reform.

The Times is still plugging away at the short-comings of our "archaic telephones," animadverting on the policy of drift and muddle that exists and laying all the blame both for real and supposititious sins of the system at the door of the Post Office administration. Except that it makes good copy we wonder what the object of it all is, and what result is expected to accrue from the mass of statistics and evidence that had been so copiously poured out. One unexpected result it has had, however. The original articles have caused the Post Office authorities to reply pointing out that they are not so black as they are painted, and that even if they have not reached the high ideal set them by their critics they have at least done as well as could be expected. Now, in two further articles the critic replies reiterating his accusations of neglect, and pointing out how many more telephones there might be than there are if only the Post Office would adopt business methods. But what is the good of advertisement if you can't supply the goods, and what is the good of starting on a great scheme of telephone development when the cry is all for economy? No doubt it could be done, and no doubt the Post Office are not the people to do it, but could anybody do it just at the moment?

American Development No Guide.

As regards what the Post Office has done, as Mr. Atkinson truly pointed out in his Presidential Address, the number of telephones per head of population is not a fair basis of comparison between this country and America. Here if we want to communicate with a neighbour we go across to his house a few yards away. But in large tracts of America the nearest neighbour may be miles distant, and "running across" is not therefore possible—hence first the telephone and then all these statistics. But a comparison of messages per telephone would doubtless tell a different story, and is therefore kept carefully in the background, while the annual cost of a telephone (another point of argument), is fallacious in a comparison unless the number of calls made on it is also given. For this reason we are sorry and not a little surprised to find *The Times* correspondent, whose identity is an open secret in electrical circles, upholding a flat rate system in contradistinction to other more economic methods of charging.

As regards the comparison of the number of telephones and of messages per telephone a close analogy could be found in railway statistics in the comparison of the mileage of line and the number of passengers carried in two given countries. For example, Russia possessed before the war over 40,000 miles of railway and the British Isles 23,910; yet the former carried 125,446,000 passengers and the latter 1,240,000,000 (exclusive of season ticket holders), or with something like half the mileage 10 times the number of passengers. We do not, of course, suggest that there would be anything like this disparity between the British and American rate of calling on the telephone, but the example is instructive of the different bases of comparison which can be adopted in dealing with statistics.

THE telephone rates in New Zealand have been materially increased of late, and now for a business telephone within one mile of the exchange the charge is £9 10*s*. per annum; within two miles, £12; within five miles, £21; and within ten miles, £34. Private telephones pay £6 within the first mile of the exchange, £8 10*s*. within two miles, £18 within five miles, and £30 10*s*. within ten miles. This is an increase of about 33⅓ per cent. in the case of most business 'phones and of about 20 per cent. in the case of private 'phones, and is the result of the increase in wages and cost of materials.

Automatic apparatus, says the *Telegraph and Telephone Age*, will be installed in the principal centres of the country at as early a date as the material can be secured. It is of American manufacture and is expected to reduce the cost of operation of the telephone system.

CORRESPONDENCE.

"A RETROSPECT."

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

Dear Sir,—I write from memory, but venture to think that the appended list is a more accurate rendering of the titles and numbers of the old London Exchanges than that made use of by the writer of the article in the December issue of the JOURNAL.

Coleman Street	1—500
Leadenhall Street	501—1000
Cornhill	1001—1500
Queen Victoria Street	1501—2000
Mincing Lane	2001—2500
Chancery Lane	2501—3000
Westminster	3001—3500
Heddon Street, generally known as Regent ...	3501—4000
Avenue	4001—4500
Hop	4501— 5000
Eastern	5001— 5301
Shadwell	5301— 5400
Stratford	5401—6000
Victoria Docks	6001—6500
Smithfield	6501—7000

Yours faithfully,

A. C. GREENING.

Sectional Engineer Office, 82, Victoria Street.

AUTOMATIC TELEPHONY IN LARGE AREAS FROM A TRAFFIC POINT OF VIEW.*

BY M. C. PINK.

THE object of this paper is to review the conditions which have to be met in a large telephone area—embracing a considerable number of exchanges already installed and working on a manual basis—and to describe the traffic features of a system which will permit the substitution of machines for human agency for the performance of the more mechanical portions of telephone operating.

During the process of conversion, and in the machine-switching system as finally developed, it is desirable to retain in as high a degree as possible the more elastic features of a manual switching system and to cover, as far as is possible by mechanical means, the powers of line selection and traffic routing, which a manual system, employing an operator for call control, affords.

Under a manual switching system the operator acts as the agent of the Administration in selecting that portion of the switchboard before her in which, for the time being, the Administration desires to locate a particular group of circuits. She also knows the desires of the Administration regarding the means by which any particular exchange in the system is to be reached, and if the Administration desires to alter the method of reaching any particular exchange, the operator is able to follow and carry out the intentions of the alteration without affecting in any way the acts of the calling subscribers. The more nearly any switching system can reproduce directive powers which are normally vested in a manual operator as described, the more closely is that system likely to meet the ultimate requirements of a large area.

Outstanding features of a large system of intercommunicating exchanges are: (1) the number of external circuit groups necessary to link up all exchanges into one system, and (2) the size of the groups of such lines which have to be developed. Under manual conditions the "A" operator can obtain for any call access to any junction on even the largest route. The more nearly the automatic system, considered as an alternative, can meet this condition so far as any originated call is concerned, the more efficient the system will be. The magnitude of this aspect of the case will be obvious so far as the London area is concerned when it is stated that the number of junctions provided for intercommunication between the various exchanges is approximately 20,000, and is rapidly increasing.

It will be obvious that in a large area at any time the number of exchanges which are approaching the end of their economic life is comparatively small and that the majority of exchanges will be fairly new. The present conditions in London are shown in Fig. 1. The capital represented by these exchanges is very considerable, and depreciation charges will have been calculated on the assumption that the exchanges would not be replaced until their economic life has been completed. Any modification of this policy would affect considerably the cost of conversion to automatic working even if it were possible to obtain automatic plant at such a rate as to permit of its installation much before the end of the economic lives of the substituted exchanges. It follows, therefore, that any scheme of adoption of automatic conditions must contemplate the *gradual* introduction of automatic exchanges into the area, with very complete facilities for handling efficiently both the traffic from automatic exchanges to the manual exchanges and the traffic incoming at the automatic exchanges from the manual exchanges. In handling such traffic there might be a considerable danger of setting up conditions which would duplicate one or more stages of the switching of a call, such, for instance, as the utilisation of a complicated series of switches in order to obtain access to the same type of control operator as would be obtained under manual conditions by the subscriber simply lifting his receiver.

In order to avoid such duplication, full advantage has to be taken of the possibilities of eliminating manual switching and affording the automatic subscribers on each new exchange, as it is brought into use, the fullest possible facilities for communicating their requirements direct to other exchanges.

Facilities have also to be afforded to operators in the manual exchanges still in commission to obtain connection with automatic subscribers either direct or through manual positions involving a minimum amount of operating work.

Furthermore, the fact must be kept well in mind that although the designation of a subscriber working on an automatic exchange must be of such a type that it can be signalled without any hesitation or doubt by *another automatic* subscriber, it must also be of such a type that it can be passed by a *manual* subscriber on the system to his *manual* operator without introducing on the *manual* portion of the line any disadvantage as compared with existing conditions. Both types of subscribers will be using the same Telephone Directory, and each entry in the Directory must appear in such a way that it is perfectly clear to either a manual or an automatic subscriber how a call to the number should be passed.

As a result of the various press notices which have appeared from time to time during the past few months it must be generally known that arrangements are being made for the installation in London of a trial automatic exchange of what is known as the panel type, and I believe the principal reason which caused your Committee to put down automatics as one of the subjects

* Paper read before the London Telephone and Telegraph Society.

to be dealt with during the session was to enable a little more information to be given regarding the panel system and the reasons why it is being installed for the first automatic exchange in London.

I had hoped to deal in this paper with the more detailed considerations of the problem in its earlier stages, but I find my time is too limited for this. I will, however, make a brief reference to junction routing under the systems so far experimented with in this country.

FIG. 1.

All systems in which the junction routing is directly dependent upon the signals dialled by the subscriber contemplate the grouping of exchanges in regions. With such grouping the provision for each region of some conveniently situated switching centre is generally contemplated—all calls for the region being passed in the first instance to this switching centre.

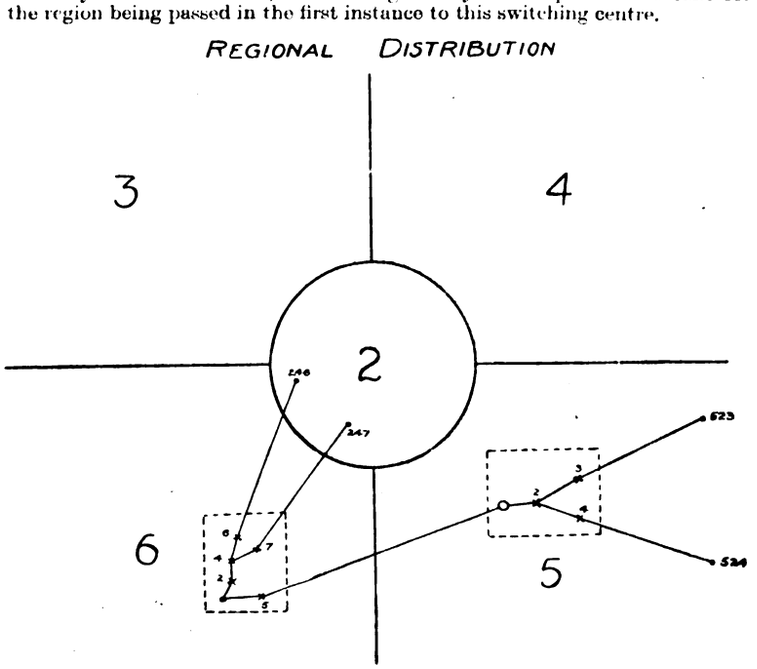

FIG. 2

In the diagram in Fig. 2, it is assumed that exchanges are designated by 3 figures. Exchanges in region (5) are obtained through a switching centre, but it will be clear that *all* traffic for the region from any one calling exchange must be similarly routed. It is possible to give direct junction service as in the case of region (2), but if this subdivision, which concentrates three selector switches at the home exchange, is followed, *all* exchanges in the region have to be supplied with direct junctions.

The next diagram (Fig. 3) shows the junction arrangements possible with the panel switching system. With this system the junction routine is not finally dependent on the impulses sent by a subscriber on exchange A, but by the impulses arranged for by a *translator*, which can be set in such a way as to vary at will the routing to any exchange corresponding to the impulses actually sent by the subscriber. Junctions can be associated directly with terminals on the first selector switch, or they may be obtained through a second selector switch, which is practically a subsidiary junction switch provided to carry the traffic on the smaller outgoing junction routes. Alternatively impulses may, if required, be retransmitted to exchange C, either for the purpose of obtaining a subscriber on that exchange or in order to gain access to a further subsidiary junction multiple at exchange C which will provide access to a subscriber on exchange G.

DIAGRAM SHOWING FLEXIBILITY OF JUNCTION ROUTING ARRANGEMENTS WITH THE PANEL SYSTEM INCLUDING THE TRANSLATOR DEVICE

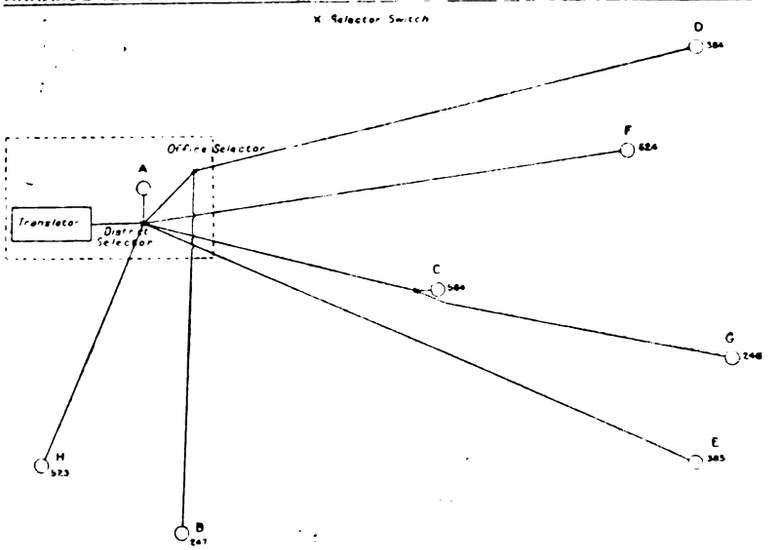

FIG 3

The American authorities have devoted considerable study to the problem of naming or numbering exchanges in large areas under automatic conditions It was found that some 70 per cent. of numbers given by subscribers are passed from memory. It was also clear that the retention of an exchange name would be of assistance to subscribers in memorising numbers in a multi-exchange area, but it was found that where numbers consisting of not more than five digits would serve any area, exchange names were unnecessary. It was, therefore, decided only to use exchange names in the larger areas which would require numbers of six or seven digits to meet the requirements of automatic workings; and that where names were retained or introduced, some of the letters of each name should be used in conjunction with the subscriber's number in transmitting the automatic signals. It will be clear that the subscriber's nemory would not be aided to any considerable extent unless the letters selected were consecutive and were those with which the name commenced.

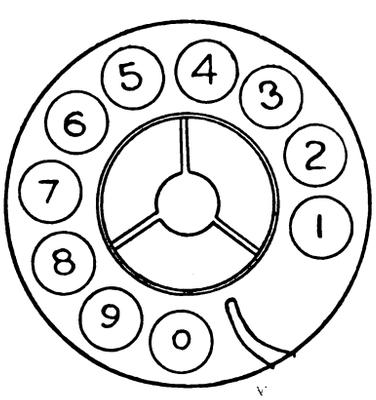

FIG 4

The normal automatic dial will only send 10 different sets of impulses, one in association with each hole. Fig. 4 shows the face of the dial at present in use in this country. I think you all know that the set of impulses relating to a particular digit is transmitted to the selecting mechanism by inserting a finger in the moveable plate opposite the digit required, turning the plate as far as the stop, and releasing it.

Digitized by Google

The next illustration (Fig. 5) shows the dial adopted for the larger areas in America and to be utilised for the first panel exchange in London. The numerals on the dial plate are engraved in red and the associated letters in black.

With the availability of these 24 letters it is possible to take the first letters of each exchange name as dial signals—2 or 3 letters according to the requirements of the particular area to be converted to automatics. In London three letters will be used. For instance, to call a subscriber Dalston 1234 with a dial of this type, the subscriber would first dial D representing the digit 3, then A representing 2 and then L representing 5, followed by the numbers 1234. It will be seen that if under manual conditions another exchange existed in the area, the name of which started with EAL, such as Ealing, the three initial letters would produce the same impulses as above, viz., 325, and one or other of the exchange names would have to be altered before automatic working could be introduced.

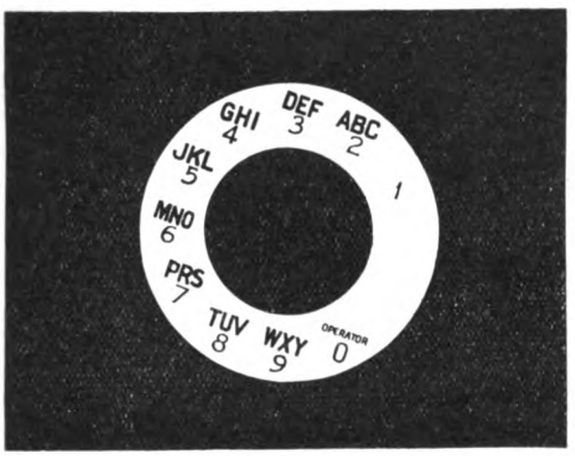

FIG 5

There are, however, few such cases in actual practice. In that portion of the London area which will be the unit fee area under the new rate proposals, there are only 8 exchange names which clash in this way under the three-letter coding system. They are shown in the following diagram, (Fig. 6). Some of the changes at least will be made next April or October in conjunction with the issue of the Directory. Although these changes will inevitably cause some irritation on the part of the subscribers at the exchanges involved, it is thought that the reasons for which they are being made will appeal to the public and that no real difficulties will be experienced.

EXISTING EXCHANGE NAMES WITHIN THE TEN MILE RADIUS FROM OXFORD CIRCUS WHICH WILL HAVE TO BE CHANGED UNDER THE AUTOMATIC SCHEME.

Existing Names.	Letter Codes.	Equivalent Dial Figures.	Existing Names which necessitate the Changes.

Stratford ...	STR	787	Streatham
Kingsbury ...	KIN	546	Kingston
Woodford ...	WOO	966	Woolwich

FIG. 6.

In connection with the installation of the panel exchange in London, it is also necessary to arrange that every exchange number of less than 4 digits shall be signalled as the equivalent of 4 digits by the interposition of ciphers between the exchange code letters and the number proper. For example, Western 12 will have to be signalled by an automatic subscriber as Western 0012. The American authorities are proposing to introduce these ciphers in the Directory in all cases. Fig. 7 shows a portion of the specimen Directory sheet prepared in connection with the modification of the New York Telephone Directory. It will be seen that the letters used for signalling purposes are printed in capitals and that any ciphers necessary to bring a number up to the equivalent of a 4 digit number have been inserted. In the London area it is not proposed at the outset to print the ciphers in the Directory in this way. 1,2, and 3 digit numbers will appear as at present, but the subscribers on the panel exchange will have to be instructed to insert the ciphers for themselves as they make their calls.

In proceeding now with a description in greater detail of some of the traffic points of the panel type of exchange, I shall make no attempt to describe the mechanical and electrical characteristics of the plant. These characteristics, which have recently been described generally by Sir Willian Noble before the Institution of P.O. Engineers and also in an article in the *Electrician*, will no doubt be described more fully by one of our engineering friends in another place. It will, however, be necessary to use a few plant terms here and there in these notes.

The Western Electric type of automatic exchange is referred to as the *panel* type because the multiple fields, instead of being of cylindrical form, as in the case of all the automatic exchanges at present installed in this country, are flat, and the multiples are built up in panels one above the other. The selecting switches operate in a vertical straight line over the panels Each selector can obtain access to one of 500 lines, but the mechanical arrangements are such that the portion of the selecting mechanism which actually establishes communication need only select over a maximum of 100 lines.

For the purpose of establishing originated calls each subscriber's line is multipled over specially-arranged panels of 300 subscribers' lines.

FIG. 7.

The next illustration (Fig. 8) shows in diagrammatic form the switching points involved in establishing calls. It will be seen that if the calling subscriber wishes to make a call to another subscriber on the same exchange the call is established :—

(1) By a line finder and selector switch, the actions of which are equivalent to the "A" operator plugging in to answer on a manual exchange and then finding a juuction in the junction multiple field. In this case the multiple is termed the *district* panel multiple.

(2) An incoming panel, which is generally specially arranged to carry traffic passing within the exchange. A selector operating over the multiple of the incoming panel obtains access to the terminal of a junction to the particular group of 500 subscribers in which the required subscriber is located; and

(3) The lines from the incoming panel lead to a selector switch which passes over the final panel until it reaches the terminals of the required subscriber. When these terminals are reached the subscriber is rung if he is not engaged.

If a junction call is made to a subscriber on another automatic exchange, the group of junctions to that exchange is found by the selector operating over the district or a subsidiary panel multiple. At the distant exchange an incoming multiple similar to that shown in Fig. 8 is reached, and through that multiple access is obtained to the particular group of lines in which the required subscriber's number is located.

Digitized by Google

If the automatic subscriber makes a call to a manual exchange, which is reached by direct junction from the district multiple, the answer of the distant manual operator by depressing the key in association with the junction on which the call is required, causes the number dialled to appear on a visual indicator in front of her—a feature which I will refer to later.

Where the panel multiple is utilised for subscribers' lines 500 numbers can be accommodated as one group, and it will follow that in a 10,000 line exchange there will be 20 groups of 500 subscribers and consequently 20 *final* multiple fields; that is the multiple terminals used for the connection of calls incoming to the subscriber. The natural sub-division of each 500 group is into 5 main sections of 100 and 10 subsidiary sections of 10 terminals in each section. The treatment of the multiple field is somewhat different when it is used for the accommodation of outgoing junctions. The unit for sub-division is taken as 10, but it is necessary to allot one additional terminal to each group of 10 working terminals. The functions of this additional terminal are :—

1. To ensure that if all the lines in the group are engaged an engaged signal is given to the calling line and the traffic overflow register is operated.

2. To ensure that in a case where two or more adjacent groups are used for a group of outgoing junctions in excess of 10, or any multiple of 10, the selecting mechanism shall continue its search for a a line from the first group to the second group until the whole of the main junction group has been tested before an engaged signal has been given.

Many exchanges would be quite unable to accommodate all their outgoing junctions on a multiple field which was limited to 500 terminals of which only 455 could be utilised for actual junctions owing to the requirements just referred to. Where therefore the number and size of the junction groups, and of the groups of service lines, on an exchange exceed the capacity of 500 terminals it is necessary to provide a subsidiary junction multiple. In very busy exchanges with a large volume of junction traffic routed over many direct routes, it will even be necessary to provide two or three subsidiary junction, multiples. The multiple field which is first available to the selector associated with a line finder is termed the *district* multiple. Large direct junction groups are connected as far as possible to this district multiple and all connections on those groups involve the use of one selector only at the originating exchange, in spite of the fact that the selection of the group is dependent upon the sending of three sets of impulses from the subscriber's dial. If a subsidiary multiple is necessary this is termed an *office* multiple, and if more than one subsidiary group is required the different multiple fields are designated Office Group 1, Office Group 2, &c.,

It will be obvious that a separate set of selectors must operate over each office multiple field provided. Access to the selectors is obtained *via* terminals on the district multiple field. The number of selectors required for an office multiple will be based upon the total amount of traffic in the busy hour outgoing to the exchanges working on the office multiple. As the circuits between the district multiple and the office selectors are purely internal it is not so necessary to secure the full availability of the office groups of lines on the district panel. The American practice is to allocate on the district multiple such terminals as can be spared for office multiple switching and to divide the group of office selector lines into two or more parts distributed over various district multiple panels.

It is interesting to compare the size of the junction groups worked under manual conditions and those which can be worked under panel multiple conditions but I am afraid time will not permit of any detailed examination of this point in this paper.

The multiple on the incoming panels consists of the standard 500 terminals, and if access is to be gained to any one of 20 groups of 500 subscribers each it will be obvious that only $500 \div 20$, *i.e.*, 25 terminals, can be allocated on any incoming multiple panel to lines outgoing from the incoming panel to the final multiple panel, or *choice* as it is called. One terminal to each choice has to be reserved for service purposes, mainly the giving of an engaged signal if all the lines to a particular choice are engaged and to record on a register the fact that the engaged signal has been given for that choice.

It will be obvious that the amount of traffic to any group of 500 lines in an exchange will exceed by far the carrying capacity of 24 lines. It is necessary, therefore, to distribute separate groups of 24 lines, multipled to a limited extent, over the incoming panels in such a way as to ensure that the total carrying capacity of the various groups of 24 will provide, on a predetermined service standard, for the total amount of traffic which is likely to come at any one time to any 500 choice.

From what I have said it will be clear that throughout the automatic switching plant alone, quite apart from the questions involved in the service relations between automatic and manual plants, a considerable number of traffic problems present themselves. If we are to satisfy ourselves that an exchange is going adequately to perform all the functions required of it, the determination of matters such as the following must be the subject of traffic investigation and calculation :—

The maximum number of lines in an average group of 300 subscribers' terminals which will be simultaneously engaged on originated calls.

The extent to which there will be variations in the calling rates in the various groups of 300 lines in spite of the best use of cross connexion facilities.

The number of sender equipments necessary to ensure that a sender becomes available for every call with a minimum of delay from the time a subscriber lifts his receiver.

The number of junctions required outgoing to every other exchange in the system in order to meet the peak load to that exchange without entailing the loss of more than a predetermined proportion of the calls passed over each route or originated for each route.

The most efficient layout of district junction multiples and, when they are required, office multiples.

A knowledge of the extent to which, when the outgoing traffic has to be sub-divided over two, three or more multiple fields, the traffic passed to either multiple field varies from day to day.

The fluctuations on incoming junction traffic and the best method of making the most economical use of the selectors on the final multiples which are available on the incoming multiple field.

The variations in the incoming calling rates which will have to be legislated for in practice in the various groups of 500 subscribers' lines.

The adequate provision of registers showing the amount of traffic passing over various portions of the switching equipment.

The organised study of the register readings for the purpose of securing the maximum efficiency combined with reasonable economy.

Turning now to the question of inter-communication between automatic and manual exchanges, it will be well to consider in detail the means which, under Western Electric panel conditions, will be employed for establishing each type of call.

Calls will be originated by subscribers on the panel exchange for :—

(*a*) Other subscribers on the same exchange.

(*b*) Subscribers on exchanges which will be reached over junctions outgoing direct from the district or office multiple.

(*c*) Calls to exchanges which are in the automatic area but have not sufficient traffic to justify direct circuits outgoing from the panel multiples.

(*d*) Calls to exchanges outside the automatic area.

PANEL SELECTOR

SCHEMATIC SHOWING ORDER OF SELECTION

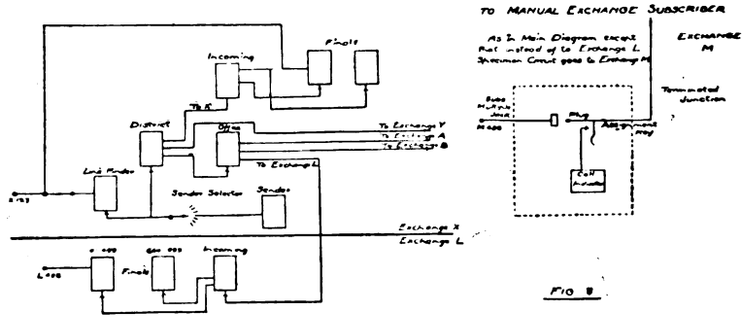

FIG 8

The treatment of full automatic calls to other subscribers on the same or to other similar exchanges has already been dealt with.

In the case of calls outgoing direct from the panel junction multiple to manual exchanges, the automatic subscribers will dial the full particulars of their call.

The exchange code portion of the call, *e.g.*, HOL if the call is for a Holborn number, will select one of the junctions in the direct group from the automatic plant to the Holborn Exchange. A special piece of apparatus known as a call-indicator will be provided, which will display, by means of lamps, the four digits of the required number in front of an operator.

(*To be continued.*)

TELEGRAPHIC MEMORABILIA.

"*Where do flies go in the winter time?*" may seem an all too frivolous question for the sober columns of even a *quasi* scientific journal, but, guided by electrical experts, one is authorised to state that these unwanted insects hide and die underneath the overhead telegraph and telephone insulators! Further, as contributory evidence, it was recently stated by *Electricity* that during the month of November last they were so numerous "as to constitute a nuisance from the standpoint of insulation maintenance." Our contemporary suggests as a cause for the little pests seeking these earthenware shelters as a winter resort the possibility of the under side of insulators being warmer than the surrounding air, as is known to be the case with the inverted cup of a snowdrop.

Waiting for a subscriber on the telephone recently, wafted over the wires came this curious piece of conversation which at first puzzled me. "Are you Shaw?" to which came the delphic reply, "Yes, and I have mumps." Then the less enigmatic voice of my correspondent came in circuit, we proceeded to business, and closed the case well satisfied with the efficiency of our national Telephone Service. By a remarkable piece of good fortune only a day or two later an official pamphlet—single sheet printed both sides, as becomes these economical times—came to hand bearing the Oldham post-mark. This leaflet announced that "A telephone call office is now available to the public at the MUMPS Post Office" and that for the sum of twopence speech could be obtained with Middleton, Oldham and Shaw. Relief at the knowledge that after all there was no oversight on the part of the authorities regarding the use of the 'phone by an infected official may well be imagined.

The list of retirements from the C.T.O. is fast adding to its numbers. On Nov. 24, Mr. T. R. Bennett, Assistant Superintendent, said good-bye to us upon reaching the three-score limit. His well-wishers, a veritable host, follow him with the kindest of thoughts and the happiest of memories. That he may find on the Essex shore that rejuvenating quality of ozone which is more to be desired than any thyroidic treatment extant is but one of the sincerest wishes which all hope to see realised in the continued life of our respected friend. On Nov. 27, Mr. "Joe" Gunter, of the same rank, also assed through the trying ordeal of parting with a department of the Civil Service which he has faithfully served for four decades. "Joe" was one of the early students of the technical side of our craft before the days of "double increments" and undoubtedly added his quota towards the efficient working of more than one phase of modern telegraphy. Among his office activities, he represented the C.T.O. on the committee of the T. and T. Society, and for many years acted in a similar capacity on the Civil Service Lifeboat branch of the National Lifeboat Institution.

Yet one more and that Mr. Harry Oakman, who left us on Nov. 30, flower in buttonhole, alert, debonnair bearing lightly his three times 20 years, and leaving behind him a record of well over 40 years' pensionable service. His personality also leaves pleasant memories and nothing but the best of the best may be assigned in the way of hopes and wishes to these telegraphers of the eighties.

While in congratulatory strain one cannot do better than to direct one's pen to Mr. Barrance, a more junior member of the C.T.O. staff, who has recently left the Cable Room for the Foreign Office, consequent upon examination before a "Pool" committee. The tact, alertness of mind and diplomacy displayed by our friend at the psychological moment during certain international pourparlers, added to his excellent knowledge of the French language and a thorough adaptability to rapidly-changing circumstances, together with his general *savoir faire*, have quite rightly led to his removal to higher spheres of usefulness. His promotion, while robbing the Telegraph Service of a most promising member, reflects no small amount of credit upon a department which is able to produce an officer of this type. To the Foreign Office or any other of the higher branches, it may be permissible to add with due modesty, that there are many more eggs of similar high quality in the C.T.O. basket should the need arise.

A reader of these columns has been good enough to forward an interesting addition to "hobbies of the Service." A well-known cable repeater officer has built himself a two-manual organ and with such special ingenuity as to be able to obtain the full power and range of an instrument of this type from a form of construction which admits of unique structural condensation. By this means the entire apparatus may easily be contained in the parlour of an ordinary country cottage. The design and decidedly new features have attracted some attention in the musical world, amongst others the organist of one of our cathedrals having taken a personal interest in the arrangement.

Music, it is by no means strange to relate, has been very closely associated with the crafts of both telegraphy and telephony, and many friends of the writer, whose interests are more specially allied to the engineering views of matters, are ardent musicians. Hughes, the telegraph engineer and inventor, was also a professor of music and that before he *discovered* the microphone.

Interesting items are always coming to hand concerning the first telegraph days in this country, and a young correspondent recently handed me an old cutting from the *English Mechanic* which placed on record the fact that Mr W. H. Hatcher, manager of Price's Candle Co., Battersea, was an ardent assistant to Mr. Cooke in the introduction of the telegraph, and before the formation of the Electric Telegraph Co. One wonders how the maker of candles and the user of electricity came together. From the same excerpt is also taken the information that during the experimental tests by Messrs. Cooke and Wheatstone, "the semaphores of the Admiralty and Portsmouth were working side by side in the same rooms in a struggle for supremacy."

It is gratifying to note that the subscriptions to the Flower Fund—a fund raised to supply the C.T.O. War Memorial Bed in Bartholomew's Hospital with flowers each week—has exceeded the sum necessary to ensure this supply for at least two years.

Other notes of thanks reach us from the Secretary of the Benenden Sanatorium Recreation and Games Fund for liberal donations from many quarters. If, as has been stated, some measure of the success of the appeal has been due to the publicity given in these columns then the editors can only express their intense satisfaction at having been of the slightest use to our less fortunate colleagues of the Post Office Service as a whole.

Slowly but surely the new system of illuminating the C.T.O., aided by something in the way of innovation as regards the mural and overhead decorations, has been creeping from one division to another with its decidedly improved influence upon all those who come under the healing atmosphere thus created. Whatever may be the ultimate verdict upon the lighting system for special conditions such as those where transmission implies a fixed position for the telegram, the general effect of the entire system is undoubtedly excellent. The murky atmosphere of London's winter months is our worst enemy, for we are still far away from those fog-less cities which were promised—how many decades ago? Neither have we yet reached that advanced stage dreamed of by John Galsworthy, who recently stated at Liverpool, "Why should not the best painters and sculptors to-day be asked to decorate schools, colleges, hospitals, workshops, even the public-houses and railway stations?" The Antwerp Central Telegraph Office had obtained something of this high standard prior to the war, and let it be added without a single protest from the entire Belgian press on the score of the "terrible waste."

One is moved at times to write upon the "little things of telegraphy" and what they mean in the larger issue of general efficiency. The failure of a Morse dot, the minuter "failure" or "extra" of "Baudot," "Western" or "Murray" signals, and in machine printing telegraphy distortions of a merely fractional character, whether electrically or mechanically produced, add very materially to the sum total of a day's troubles. When one has watched such distortions, say at a repeater office, and has noted that the margin has yet proved sufficient to produce the correct letter or figure it has been a real cause of wonder and admiration for the inventors' art, the constructor's mechanical production and the mechanic's maintenance. Yet the day, the hour or the moment of small things will not be neglected by the watchful *dirigeur*. Dirty contacts in Baudot keyboards will be avoided, blunted or minutely out-of-gauge perforations on Creed or Western or Murray or Siemens circuits will be keenly watched, and at the first sign of weakness remedied.

Then there are other little items. The incorrect date on a telegram, for example, and where "numbering" of the traffic is in vogue indistinct figures. These two together with the omission of a.m. or p.m. are amongst the most proficient of time-wasters when it comes to secretarial or other inquiry regarding a telegraph message, especially if this be of foreign origin.

It was thought that when type-printing telegraphy came to stay all ambiguity regarding a letter, figure or character would be at an end. This has been by no means proved to be the case, simply because of the neglect of little things, and sometimes, let it be added, by the institution of so-called "little economies." Letters or figures that cannot be read off at once with certainty all detract from the high water mark of efficiency, all tend to slow down the general output, to cause non-deliveries and to add to unremunerative service correspondence. The public here at times are by no means blameless as regards certain typed telegrams.

Students of "wireless" may not all be aware of the remarkable properties of silicon and germanium, which exhibit the two highest thermo-electric powers.

It is also a curious fact that silicon is either strongly electro-positive with respect to copper or electro-negative, according to the method of preparation, and by combining the positive and negative varieties thus obtained, we can construct a thermo-electric couple displaying the enormous differences of potential of 1,000 microvolts per degree centigrade. The small quantities of impurities, such as iron, which are always found in silicon, diminish the thermo-electric power without, however, changing its sign. By crystalising the silicon in aluminium to purify it, we obtain a strongly positive product; by crystallising it in silver or in tin, in each of which it is less soluble, we arrive eventually at an electro-negative product. Experiments with germanium demonstrate that this body presents the highest thermo-electric power next to silicon. These two substances also resemble each other in other respects, in particular, in their remarkable power of rectification with respect to the Hertzian oscillations.

The Siemens system of high-speed type-printing telegraphy experiments are still proceeding, and as we go to press have reached the point at which traffic has been possible between London and Berlin, utilising two wires for one installation. Duplex on one wire, it is anticipated, will be the next development.

The Telegraph and Telephone Department of the German State has been directing its energies to experiments on the use of high-frequency currents in wires for the transmission of several simultaneous sets of telegraphic or telephonic signals, or both.

According to the *Elektrotechnische Zeitschrift* studies have been made in methods of connexion, filtering out at the receivers, speech amplifiers, &c.

Since October, 1919, the line between Berlin and Hanover (300 km.) has been in operation for threefold telephonic conversations, while it is

Digitized by Google

possible for subscribers in the two towns to converse together with their normal instruments. A similar installation is in use between Berlin and Frankfurt, a distance of twice the length. The high-frequency currents, it is stated, are generated by Telefunken oscillation valves and may be adjusted to have wave lengths between 200 and 20,000 metres.

This same journal states that the following developments have been attained along the less well explored fields of multiplex telegraphy: "The first practical tests were carried out on a line 600 km. in length between Berlin and Frankfurt Main. The signals are given by negative current pulses, while the positive current is used for disconnecting.

The pulses are not sent directly into the line, but actuate a relay that throws the high-frequency generator on and off the line in step with the signals. At the other end of the line the high-frequency currents are amplified and admitted to the receiver. The installation has been operating on duplex work since last December, and in 8 to 9 working hours handles up to 2,000 telegrams, or 30 per cent. of the total service between Berlin and Frankfurt. Recently the system has been used for six-fold telegraphy on a line carrying in addition one ordinary telephone conversation. This corresponds to a speed of 4,000 letters per minute, or in 8 hours 16,000 telegrams of 10 words, with an average of 6 letters, assuming that only half the total time is actually used for transmission.

A few weeks ago a 150 km. circuit between Berlin and Magdeburg has been used for transmitting two simultaneous telegrams by high-frequency currents and Hughes' apparatus, in addition to an ordinary telephonic conversation.

How some of the every-day systems, machinery apparatus and processes may strike the uninitiated "outsider" as on the marvellous side may easily be imagined even by those of us who are constantly in touch with a multitude of electrical and mechanical devices. I was, however, somewhat surprised recently to read in the sober columns of a highly-technical publication *a propos* of the developments of high-speed multiplex telegraphy in the U.S.A. that one of the remarkable features of the system appeared to the writer of the description to be that "*by means of a switch the system may be immediately turned from multiplex to Morse.*" Wonderful maybe, but not exactly the most modern feature of twentieth century telegraphy!

The December gales have been rather unkind to some of the Anglo-Continental telegraph communications, so that one longed for extensions of the underground system to our East and South Coasts. There would then be no need to call upon the village postman to make crosses at test boxes while he, poor fellow, was puzzling his head as to which was "Up" and which was "Down" side, and wondering too whether he would finish his "Parcel-despatch," while, incidentally, the metropolis was impatiently waiting to obtain a wire or two with the other shore of the North Sea.

A recent visit to the premises of the Western Electric Company proved a very interesting experience, and an opportunity for which one would like to place on record an expression of grateful appreciation. There was no mistaking the thoroughness of the demonstration and the whole-hearted enthusiasm of the demonstrators.

The latest developments exhibit some excellent features, notably the new type-writer receiver which is capable of simultaneously printing-off a dozen carbon copies of any telegram straight from the telegraph wire. It is a sturdily built machine and the laboratory test to which the apparatus was subjected included the printing of over two million words without an error. This portions of the machinery appears to be rather noisy, although it is only fair to add that the company's engineers are hoping to reduce this special disability in time.

The arrangement by means of which a number of channels may be forked off to private subscribers, the synchronism being completely controlled by a distributor which may be situated two or three miles away is particularly ingenious. The possibilities of this scheme are great, but at present the system is likely to be confined to the United States, where a number of these particular sets are apparently on order. The method of synchronising by means of a movable plate of segments capable of rotation through 360° also presents new facilities, and a speed correction which checks both fast and slow movement forms an extremely interesting feature.

Particularly interesting, too, and especially to those who have seen the French method of "repeating" on long distance multiplex type printing circuits, is the retention of "rotatory repeaters" instead of the British system of ordinary fast speed (Wheatstone) repeaters for the purpose.

The system of transmitting from the distributor *through a relay* which repeats the pulsations to line has been adopted, a system which has been utilised by German engineers for some years both in "Baudot" multiplex and Siemens' automatic.

One thing only was lacking and that a practical trial on a wire of some length, say, London to Rome. The opinion is expressed in advance that such a trial would prove the superiority of the present Baudot type of installation for lines of the unstable nature quoted. Upon circuits where stability was the outstanding feature, such for example as any of the long main lines of Great Britain, the perforated typewriter slip system would be quite suitable. Here again, however, there are other queries. Would not the maintenance cost of so complicated a piece of mechanism as the Western Electric printer far exceed that of the present Baudot receiver with the more than equal sturdiness and the decidedly simpler mechanism of the latter, not to speak of the heavier prime cost of the former?

There is still a shyness on the part of certain continental administrations to the duplexing of Anglo-foreign lines. In some cases circuits which worked wonderfully well before the war by this economical method, no longer yield the traffic output of which they were then electrically possible, or else relapse into "simplex" day after day. It may be agreed that post-war standards as regards continental land lines cannot at present be demanded, but it is to be hoped that something approximating thereto may not much longer be delayed.

Unfortunately for the British Post Office the British public, as also a certain public on the other side of the Atlantic, are too easily inclined to attribute the consequent heavy delays to the "ineptitude of British State Telegraphs," a charge not *maliciously* ignorant, but certainly ignorant and most decidedly unfounded.

Meanwhile the British Engineering Department is keeping well in view all possible means of assisting our foreign correspondents, and the extension of a high standard underground system of wires to the North Sea coasts and to other submarine cable-heads may be anticipated. That the early realisation of such a scheme may be practicable and thus definitely set at rest any doubts as regards the insulation of the British coastal routes that may still be in the minds of continental administrations is the constant petition of all those whose fortune it is to work or to be in any way responsible for continental telegraph communications. Such a system radiating to *all* coastal cable landing points would place the British telegraphs in its correct setting of a well-nigh impregnable standard.

Mr. John Lee's paper on "Scientific Management" drew a very considerable audience at River Plate House on Monday, the 13th ult. The lecture was in concentrated form as regards the matter it contained, and to those who heard for the first time a dissertation on the subject it proved a veritable lesson in careful and attentive listening.

When the lecturer had finished, there was a concensus of opinion that "we will hear thee again of this matter," for it was not possible to thrash out in one brief hour the pros and cons of a subject which touches on a question so vital to the interests of our plagued and tried human nature. Upon the human side of this matter Mr. Lee made a strong appeal for due consideration of the development of the soul of mankind, its higher self. With a charm of pleading manner he asked whether it was really worth while to plan and scheme and measure and calibrate human effort and to "organise" it out of its individuality till it became standardised and stunted.

Mr. Lee, with the poetic expression and emotion of three or four generations behind him, was at times inclined to sway one off one's reasoning balance in his laudable appeal for the humanites. Other speakers suggested "co-operation" as an alternative to "scientific organisation," but co-operation surely needs "organisation" and "organisation" simply belies its name if it be not accurate and scientific.

A scientific management at its best, could surely be devised which would teach us how to do things the better way without breaking the heart or spirit of man. Need scientific management rob a man of his individuality?

Scientific management might teach a man the easiest way to hold a Morse key—with or without his "thumb well under"—according as the expert might after experiment decide; he might teach us the smallest number of motions necessary to gum Creed or Wheatstone or Hughes slip, the easiest way to manipulate the latter keyboard or to touch-type with our type-writer, and yet without destroying individuality. One questions even the possibility of reducing the human mind to uniformity. There are no two finger prints alike!

J. J. T.

LONDON TELEPHONE SERVICE NOTES.

A Happy and Prosperous New Year.—Here is a "standard expression" used so freely at this period of the year by people of all classes and professions, even by the critics of the oft-repeated phrases adopted in telephone operating. Like all formal expressions its value depends on the degree of sincerity conveyed by the speaker as well as on the fitness of the expression to the occasion. Individually we all look forward to a just measure of happiness and prosperity in the year just commenced. A large portion of our time will be spent pursuing the profession we have adopted, and that thought gives rise to the question whether the season's greeting is fitting to our official life. Reviewing some of the achievements of the past year we find satisfactory progress has been made on all sides. The "service," which engages the attention of the majority of our readers, perhaps more than any other item, shows an immense advance. The speed of answer which stood at 8.6 seconds for the month of December, 1919, has improved by approximately 3 seconds, so that it is now closely approaching the standard at which the Administration aims. Similarly the average time taken to clear local connections is now in the neighbourhood of 5.5 seconds. The percentage of operating irregularities has dropped to a figure better than that obtained prior to the war. Confirmation of the improved quality of the service may be held to exist in the fact that the ratio of written complaints to subscribers' lines is now less than in pre-war days. These figures of course apply to the London Exchanges as a whole. The number of exchange lines in the London Telephone Area has increased by about 18,000 during the past year and the highest volume of 24 hours' originated traffic so far recorded was reached. Progress has, therefore, been achieved in all directions and is, moreover, being maintained. In the current year we are to have several new exchanges and extensions to existing exchanges. A definite advance will be made in the application of machine switching to London, and the opening of the new Toll exchange will mark a considerable improvement in the handling of provincial traffic.

Digitized by Google

In so far as prosperity is measured by income, material advances can be recorded even if they are not yet to the entire satisfactory of the staffs of all grades. The foregoing factors, together with the harmonious working in the London Telephone Service of the Whitley machinery, justify the repetition of the wish "A Happy and Prosperous New Year."

St. John's Ambulance Association.—Among the various institutions to which the women of the London Telephone Service give their support during their leisure hours perhaps the one least known is that of the Post Office Ambulance Corps. The London Telephone Service has a branch of the Corps known as the G.P.O. South (Telephones). From that branch a team entered the fourth annual competition held on Nov. 17 last for the women's trophy and were successful in winning it. Teams competed from The Accountant General Department, G.P.O. South (Telephones), G.P.O. West (C.T.O.), Money Order Department, and Saving Bank Department. The former holders of the trophy were the G.P.O. West (C.T.O.) branch, the team from which took second place on this occasion. Our team comprised :—

Miss A. Drewe (CQ), Leader,
Miss E. Drewe
Miss F. E. Foster
Miss B. L. Webb
} Trunk Exchange.

We congratulate them heartily on adding to the many laurels gained by the staff of the London Telephone Service.

The Post Office Ambulance Corps is an unofficial and voluntary organisation, which has for its objects the assisting of officers to become certified in "First Aid" and "Home Nursing" and efficient in "Ambulance" work generally. It provides a trained body of men and women in the office capable of rendering assistance in cases of accident or sickness. A further object is the recruiting of members for the No. 58 (London Post Office) division and the No. 28 Nursing Division, Prince of Wales Corps, both of which have been formed to enable members of the Corps, should they so desire, to perform ambulance duty on public occasions and to obtain hospital training.

Lectures and practices are arranged, and the next course in connection with the G.P.O. South Branch commences during this month. New members are urgently required to enable the work to be carried on and extended, and any members of the staff who would like to go through either of the courses will be welcome. The Secretary of the G.P.O. South Branch is Miss E. Mulvany, of the London Trunk Exchange, and she is anxious to receive applications for membership or to answer any questions concerning the classes. The Controller is a patron of the Post Office Ambulance Corps, and Miss Heap is the President of the local branch. Miss A. Drewe is a member of the Nursing Division, and in that capacity performed service in Egypt during the late war.

The Christmas Fair.—It is no mere form of words to say that the Christmas Fair which took place early last month was an immense success. The Memorial Hall authorities express the view that it eclipsed anything of its kind previously held in the building. Visitors streamed up the broad staircase unceasingly and at times it looked as though another individual could not squeeze into the hall. The army of helpers at the stalls, in the refreshment room, at the doors and in the corridors directing the visitors worked untiringly. Telephonists and Supervisors as waitresses, Assistant Superintendents of Traffic as showmen, vied with each other to achieve perfection in their new calling (or shouting). Donations, which were greatly appreciated, were received from colleagues in various parts of the country. The amount—two thousand guineas—raised in the two days is some indication of the work of the whole staff in London in preparing articles for sale. The concerts under the direction of Mr. Pounds and the two dramatic parties were well patronised, and an appreciable sum was thus added to the proceeds. A fuller account will be found elsewhere in the JOURNAL.

We were glad to welcome among others Mr. Pike Pease (the Assistant Postmaster-General) and Mr. A. R. Kidner (Assistant Secretary-Telephones).

The London Telephonists' Society.—The November meeting of the Society, at which Mr. M. C. Pink read a paper entitled "My Impression of London Telephones" by Sadie Worth, telephone operator, New York City, was very successful. The paper consisted of a series of letters from Sadie to Poppy and was the more interesting on account of the original style in which it was presented. Notwithstanding that Sadie was having what we should call colloquially "a busman's holiday" and was writing such a lot of shop, she introduced an amount of humour which made her letters quite pleasant. In contrasting the general conditions of service of the exchange staffs in this country and the United States, the advantage seemed to lie with the telephonists of the British Post Office, but our readers will no doubt have the opportunity of judging for themselves when space for the letters can be found in this JOURNAL. Mr. Pink received a very enthusiastic vote of thanks at the conclusion of the meeting.

An additional meeting has been arranged for the month of January, to be held on Thursday, the 13th, at 6.30 p.m. at the Sunday School Union in Old Bailey, E.C. On that occasion Miss Heap will read a paper entitled "A Little Holiday in Italy before the War." The paper will be illustrated by lantern slides, and both the subject and author are sufficient recommendation to ensure a large audience.

The membership of the London Telephonists' Society was never in a more favourable position as regards numbers than now. At the time of writing these Notes the roll contains the names of 950 members, and there is every indication that by the time the notes appear in print the number will be increased to 1,000 or more. The President and Committee are to be congratulated on this result, which has, no doubt, been achieved largely through the excellence of the papers which the Society has secured. So far the attendance at the meetings has been no larger than has comfortably filled the dining room at Museum, but with the membership now existing larger attendances are looked for and a return to the hall of the Sunday School Union may then be necessary.

The Telephone and Telegraph Society.—It was unfortunate that the December meeting coincided with a meeting of the Institute of P.O. E.E's., for a number of members found some difficulty in deciding whether to attend to hear Mr. John Lee's paper on "Scientific Management" or to accept the invitation to hear the paper on the subject of "Wireless Developments in Telegraphy" read by Mr. Shaughnessy. The attendance at both meetings suffered, but nevertheless Mr. Lee had a large audience. His paper was greatly appreciated from the fact that he urged the need for adequate consideration of the worker and the enlistment of the worker's co-operation in all schemes of scientific management. These factors have not always been accorded their proper value by all past students of the subject, but here are indications that the tendency of the age will secure for them greater prominence. In this respect the paper may be regarded as an argument in favour of the Whitley movement.

Why is the Society called The Post Office *Telephone* and Telegraph Society of London ?

Why is the JOURNAL entitled The *Telegraph* and Telephone Journal ?

Was he of the sister service who last month in the leader headed "Automatics for London" referred to the London *Telegraph* and Telephone Society ?

Is the author of last month's L.E.D. Notes who referred to the Post Office *Telegraph* and Telephone Society "offifficient ?"

The London Telephone Service, Whitley Committee.—It is interesting to read the first annual report of the work of our Whitley Committee, and to read in its concluding paragraph : "So far as the London Telephone Service is concerned harmonious and satisfactory utilisation of the Whitley machinery is proceeding. The discussions which have ensued so far have been informative, and should prove of value from both the official and staff point of view."

The distribution of the seats among the Associations representing the various grades of officers in the London Telephone Service is as follows :—

Union of Post Office Workers	5
Controlling Officers' Association	1
Association of Civil Service Women Clerks	1
Association of Civil Service Writing Assistants	1
Association of Traffic Superintendents	1
Association of Civil Service Clerical Officers	1
Association of Contract Officers	1
L.T.S. Supplementary Clerks' Association	1

This arrangement will continue throughout the ensuing year. Six meetings of the Office Committee have been held during the period under review. An indication of the variety and range of the subjects discussed is obtained from the list of items given below :—

Matters affecting mainly the Headquarters Staff : conditions under which officers might be allowed in exceptional circumstances to commence duty at a different time from the normal hour of commencement of duty ; redistribution of senior clerical officers ; paperkeepers' duties ; registry accommodation ; effect on staffing arrangments of introduction of new telephone rates and change in system of accounting ; need for appointment of Supervising Sorting Assistant on Directory Section ; Writing Assistants—compulsory overtime and promotion to Women Clerks' vacancies ; various matters relating to Girl Probationers and the Male Messenger Staff, *e.g.*, overtime, duties and status of Assistant Head Messenger.

Questions affecting mainly the exchange staff :—Overcrowding in the London Trunk Exchange ; Staffing conditions at Directory Centre Exchanges : a recommendation by the West Traffic District Whitley Committee for an increase in the tea relief at Exchanges ; possibility of transferring Night Telephonists and Call Office Attendants to Coin Collectors' positions ; possibility of placing on permanent staff temporary full time night telephonists engaged during the War ; medical attendance arrangements for night telephonists ; press announcements concerning increases of pay to exchange staff.

Two Sub-Committees have been appointed, with the terms of reference quoted below :—

(1) "To consider the question which would arise as a result of the introduction of new telephone rates and any change in the system of accounting."

(2) "To consider and report upon the conditions obtaining at Directory Centres and the best means of improving the arrangements for dealing with Directory enquiries. "

Neither of these sub-Committees has yet concluded its sittings.

The District Committees are also in active operation, and have already discussed a number of matters of interest within their district.

To our Whitley Committees we repeat the wish 'A happy and prosperous New Year."

LONDON ENGINEERING DISTRICT NOTES.

AN interesting ceremony took place on Nov. 16 at St. Martin's le Grand. The occasion was the presentation to the Engineer-in-Chief of a book containing the signatures of a very large proportion of his staff, as a memento of their good wishes on the honour of Knighthood being conferred upon him. The book was richly embellished and enclosed in a handsome casket.

Mr. A. J. Stubbs, in making the presentation, referred to Sir William Noble's valuable services to the State and the esteem in which he is held by all who know his sterling worth. He likened the dignity that had been conferred upon the Engineer-in Chief to the snow-cap on the mountain's top, which, though not increasing the greatness of the mountain, does emphasise it.

Sir William assured those present that he valued his knighthood not on his own account, but because it conferred distinction on the whole engineering staff.

Before this number of the JOURNAL is in print Mr. J. E. Taylor will have started his duties as Superintending Engineer of the South Midland District in place of Mr. Robb, who brought his official career to a close on Dec. 31. Although Mr. Taylor's stay in the London Engineering District was not a very long one, yet it was sufficient to enable him to endear himself to his colleagues, who regret his departure and offer him their best wishes for success in his new sphere of activity. The vacancy at Denman Street has been filled by the transfer of Mr. R. A. Weaver from the South Eastern District. The change has involved a rearrangement of duties of the London Assistant Superintending Engineers. Mr. Greenham is now responsible for those matters formerly attended to by Mr. Taylor, and Mr. Weaver for matters relating to Internal Construction.

* * * *

It is hoped ere these notes are in print to have completed extensions of the Hornsey and Victoria Exchanges, and, if certain long outstanding stores come to hand, to have cleared up a number of other smaller extensions. In the February number it should be possible to report the opening of a new C.B. Manual Exchange at Harrow, to replace the No. 9 switchboard hitherto in use. The work on the various relief exchanges is being pushed on with all possible speed. Langham will be the first to open and Chancery the second. The remaining two—Grosvenor and Minories—happen to be in different sections, and the Sectional Engineers concerned are each determined to complete his first. The loser is to buy and wear a Sandringham hat as a punishment.

* * *

A little while back an article on the Electrophone Service appeared in this JOURNAL. The number of subscribers to the system is still increasing rapidly. In order to make it possible to meet all demands for exceptionally popular entertainments it has been found necessary to employ thermionic valve amplifiers. The experimental installation of these has proved so successful that it has been decided to equip a greater number and in a permanent manner. At times there have been as many as 220 subscribers connected to one music line.

A similar system of amplifiers is to be introduced shortly in connection with the L.T.S. telephonists school. A whole class of students will be enabled to listen simultaneously to one working telephonist. Is the Post Office behind the times? The answer is in the negative.

* * *

The lecture room of the Royal Society of Arts, John Street, Adelphi, was crowded on Wednesday Nov. 17 when the Chairman of the Society, A. Campbell Swinton Esq., F.R.S. gave his inaugural address

The subject chosen was that of "Wireless Telegraphy and Telephony," and it was illustrated by working demonstrations of apparatus.

Standing among those crowded in the doorway of the lecture room and unable to get inside, we were impressed by the large number of very elderly people present.

Some appeared to be early Victorian scientists returned to earth in order to see some of the latest developments of applied science. There was one dear old lady in the front row gazing with awe on one of the latest thermionic valve receiving sets.

The lecture itself may be described as a very fair epitome of the latest practice so far as wireless work is concerned. The principal feature of the demonstration was the exhibition of some up-to-date Creed telegraphic apparatus. Wireless messages were received *via* an aerial fixed on the roof of the Society's premises and were rendered audible to the audience on a loud-speaking telephone receiver. The signals were also received on the Creed receiving apparatus. The latter operating the perforating mechanism prepared a special tape for the printer by means of which the message was reproduced in Roman letters. It was finally exhibited on the screen through an optical lantern. Messages in this way were dealt with from Portsmouth and Paris, that from the latter being a special message from the Eiffel Tower Station by the courtesy and permission of General Ferie, Head of the French Wireless Administration. A demonstration of wireless telephony was also given, spoken messages, whistling solos and gramaphone selections being clearly reproduced and audible throughout the lecture room.

The lantern slides were excellent. The only general criticism that one can offer is that far too much time was spent on receiving and reproducing the messages, which were unduly long. The time left for explanation of the diagrams and general principles was thus so curtailed as to be of little value for the purpose of gaining information.

* * *

It would be interesting to know what percentage of surplus war stores has been put to useful purpose since peace was declared. Those who take notice as they move about the streets of London will have observed a new type of Post Office Engineer's truck with wire spoke wheels and flat solid tyres. These same trucks were not so very long ago Hotchkiss gun ammunition wagons and were used for destructive instead of as now for constructive purposes. The Post Office saved a great deal of money by purchasing a quantity of the wagons very cheap and converted them at small expense into serviceable trucks for external linesmen.

Talking of taking notice reminds one of the following lines culled from one of Sir Oliver Lodge's books :—

> "The ordinary run of men live among phenomena of which they care nothing and know less. They see bodies fall to the earth, they hear sounds, they kindle fires, they see the heavens roll above them, but of the causes and inner workings of the whole they are ignorant, and with their ignorance they are content."

The work of the Engineering Department is so many-sided, and demands such constant study of technical and scientific literature, that its members are not likely to fall into the unthinking condition referred to. Scientists are producing more and more evidence that life is a form of electric energy, and the originator of the expression "live wire," to denote a keen-witted and active person, probably had this theory in mind.

There is no lack of "live wires" in the Post Office Telephone Department

* * *

In America much greater use is made of motor vehicles as an aid to telephone engineering than in this country. This is not because the Post Office is backward in adopting time and labour-saving methods, but because the conditions on the other side of the Atlantic are more favourable to their use. In New York apparatus is despatched to the subscriber's premises in advance of the fitters' visit, and it is claimed that much time is saved by such an arrangement. Experiments in this direction were made in London many years ago and it was proved that the conditions were not favourable, and the scheme was abandoned on financial grounds. The conditions now have changed in some respects and further experiments are being carried out with a view to seeing just how much the progress of the work can be hastened by the employment of motor vehicles. Anyone who knows the congested state of the streets within a mile of the Mansion House will readily understand that in that area more time may be lost than gained through vans being blocked for long periods in narrow streets. This, added to the fact that fitters can reach most of the subscribers premises on foot or by using the many facilities for rapid transit and carry the necessary stores with them, puts out of court the idea of doing the whole of the delivery work by van. The heavier items must, of course, be delivered in this way.

In addition to the motor vans now in use there is qute a little fleet of motor bicycles with side cars for the use of travelling supervising officers. These have proved a great boon, permitting as they do works in progress in remote parts of the district to be more frequently and thoroughly inspected.

* * * *

A GALLANT ACTION.

It is with great pleasure that we publish details of a very plucky deed on the part of one of the Department's officers.

On Nov. 17 a horse attached to an unattended laundry-van in Queen's Avenue, Muswell Hill, took fright at a passing motor lorry and galloped towards The Broadway, causing great commotion among pedestrians in the vicinity.

Seeing the possibilities of danger, Mr. H. W. Spiers (N.E. Internal Section) who was passing, clambered into the van. He was able to rein up the horse, which he brought to a standstill within a few yards of The Broadway.

There is no doubt that Mr. Spiers' presence of mind and prompt action averted what might have been a serious accident.

One of the Headquarter's Engineers has a small boy of an enquiring turn of mind and a coffee grinder. Many great discoveries have resulted from performing the same experiment on a number of different substances. The small boy in question recently ground up a packet of "Lux," and, as his father says, next morning for breakfast he was regaled with Café de lux. A position in the Research Section has been earmarked for the budding scientist.

At the invitation of the Western Electric Co. a few of the District Headquarters staff recently attended the company's City Offices for a demonstration of the latest developments in Western Electric machine telegraphy and telephone repeaters. The already well-known Western Electric "start-stop" printing telegraph apparatus, so called from the fact that its distributor is in operation only during the transmission of a signal, was shown in operation. Like the Baudot, on which it is based, it utilises a combination of five impulses, but these are originated in the transmitter by means of a perforated tape prepared on a pertorator with typewriter keyboard. The reception is in the

form of page printing, and as the apparatus can readily be duplexed the transmitting operator seated at the keyboard can see the reception, which is in full view. The apparatus is capable of fifty words per minute, and a case was cited in the States where an operator capably handled the entire duplex working at one end.

The Western multiplex printing telegraph, with several important improvements, was also exhibited. It is an exceedingly compact apparatus with all parts conveniently arranged for adjustment or replacement, particularly in regard to the distributor. One novel feature is the arrangement of small signal lamps provided as a direct visible means of regulation.

The Western Electric telephone repeater was represented by two demonstration circuits, one two-wire of 38 standard miles which was reduced to 12 by means of two repeaters and the second, a four-wire circuit of 72 standard miles equivalent, reduced to the same figure by the repeaters. The transmission was excellent in both cases. An interesting development was a test panel, which, in addition to the usual repeater testing arrangements, enabled the testing officer to ascertain on direct reading instruments the repeater gain in terms of standard miles. The tendency for improved transmission on very long trunk lines is towards the 4-wire system using cable with small gauge wire—four 20 lbs, wires are more effective than one pair of 40 lb. wires. Instructive charts were exhibited showing possible arrangements of the repeaters. One, a map of the United States, indicated the transcontinental circuit between the Atlantic and Pacific, extended to Los Angelos, a total distance of approximately 4,000 miles. Transmission was obtained through the repeaters and the circuit thereby improved to the equivalent of 12 standard miles.

An interesting lecture was given by Mr. E. H. Shaughnessy, O.B.E., M.I.E.E., Staff Engineer, at a meeting of the Institution of Post Office Engineers held on Dec. 13. The subject was "The Development of Wireless Telegraphy. Mr. Shaughnessy is an ideal lecturer, having a facile delivery and the knack of making an abstruse subject seem simple to his hearers. He traced the development of the apparatus that is now employed in the various commercial systems, dwelling principally on the Poulsen Arc, the high frequency alternator and the valve oscillator as the basis of transmission systems. The lecture was illustrated by a number of excellent lantern slides and some successful experiments, including the Dudell singing arc, the singing valve, high speed reception and the Post Office wireless call device. Mr. Shaughnessy would have extended his lecture beyond the allotted period had not the hall been engaged for another meeting the same evening, and his audience would have gladly sat all night and listened to him. He promised that others in the Wireless Section of the Engineer-in-Chief's Office should follow his example later and give the members of the Society the pleasure of hearing more about this fascinating subject. This promise must be redeemed.

TELEPHONE TARIFFS.

As we go to Press we have received a copy of the Report of the Select Committee on Telephone Charges. The Committee have accepted the Post Office proposals for the abolition of the unlimited service and measured rate tariffs and the adoption of a uniform message rate for all classes of service, and they approve the proposals for quarterly accounting in respect of all rental fees and charges.

The quarterly rental payments will be as follows:—

London	£2	2	6
Birmingham, Glasgow, Liverpool, Manchester	£2	0	0
Elsewhere	£1	17	6

Each originated local call, 1½*d.*; no charge for incoming calls.

"TAYLOR O' MANCHESTER" RETIRES.

MR. WM. TAYLOR.

THE reputation of some men become almost inseparable from the places in which they have done notable work, and so we have among eminent preachers "Robertson of Brighton," Spurgeon and his Tabernacle. There are too in the English telephone world three notable Telephone Taylors, to wit:—"Taylor of Brighton and 'Brum.,'" "Contract Taylor of G.W. and L.T.S.," and "Taylor o' Manchester."

The last-named officer, Mr. William Taylor, having attained the 60 years necessary to qualify for a first-class retirement while serving as District Manager at Lancaster, was the recipient on Nov. 30 of several concrete gifts from his colleagues past and present testifying the high regard in which he is held by those who know him. A silver tea service and umbrella came from the local staff, past and present, and a gold curb watch chain from his co-District Managers.

At the request of the Lancaster staff the presentation of the tea service was made by Mr. T. A. Prout, of the Telephone Branch of the Secretary's office, who recounted his long personal and happy experience of the recipient.

THE LONDON TELEPHONISTS' CHRISTMAS FAIR, see p. 55.

For over 26 years Mr. Taylor was second-in-command at Manchester and there are few men in the city better known than this telephone Taylor, who is a veritable "Manchester man."

He is a thorough-going Telephone Encyclopedia and what he does not know about telephones in Lancashire is not worth knowing, and what he does know would form the basis of an interesting article for our JOURNAL.

Notwithstanding nearly 40 years strenuous telephone service he retires clean-shaven with a debonair moustache as indicated by his latest photograph looking younger than he did with the side-whiskers of middle age. He tips the scale at 14 stone and will give the best bowlers of Blackpool many a hard game, and let us hope keep it up for many years to come.

Mr. Taylor was gratified to receive on the morning of his last day a kind letter of congratulation and thanks from Mr. A. R. Kidner, the Assistant Secretary, who conducts the Telephone Branch of the Secretary's Office.

TRAINING AND SCIENTIFIC MANAGEMENT.*

BY JOHN LEE.

SCIENTIFIC MANAGEMENT is hardly well-named. It is a theory of what might better be called executive management. It belongs essentially to that section of management as a whole which is concerned with the immediate direction and control of staff, and it occupies itself principally with the detailed performance of work. Important though that is, we cannot agree that it covers the whole ground of management. It is curious that in America the more distant phases of management, as we may call them, the formulation of policy, the working out of the broad principles of production and of sale, are taken for granted. No one needs training or scientific method, apparently, to be at the head of half-a-dozen trusts or to manage the financial interests of various huge corporations. It is understood that the more immediate *managers* need this training, and it is for them that Scientific Management has been evolved. Whilst, however, I would protest that this conception of Scientific Management is far too narrow in its outlook, I believe that we have *much* to learn from it. Possibly I would apply its principles a little differently; certainly I would look a little differently both at its psychology and its economics. For all that it represents a vast amount of study, research, observation *and* comparison of all kinds of human work, of the mental operations or physical acts involved, of the methods by which stimuli are to be given and rewards allotted, of the methods by which staff can be interested both in their day-by-day work and in its eventual or corporate results. We must admit, whatever analysis to which we may subject Scientific Management, that this is a worthy aim. We have been woefully lacking in an appreciation of the human side of industrial operations; incidentally, I am not at all certain that the exponents of Scientific Management, with all their minute study and observation, have shown a true appreciation of the human side of individual operations. However, at this stage I am not presuming to analyse Scientific Management. I am only making for it the simple and, as I believe, the just claim that it has moved the focus of interest from the machine to the man, that it has given to the human side of industrial operations, at any rate, the tribute of minute study.

Scientific Management has come to us from America, where labour conditions in the sense of labour organisation to protect its own interests are far different from conditions in England. Consequently, it comes to us rather from the capital side than from the labour side of the long-continued issue, and justly or unjustly labour has looked rather coldly upon it. Yet it has succeeded in many industries, though in the main they have been industries rather of specialised types. It did not begin as an attempt to exploit labour. That charge has been made again and again. It began in what seemed to its sponsors to be an effort to unite the interests of employer and worker; it formed as a basis many doctrines and theories which were a shock to the old-fashioned employer. It looked at the worker through eyes which had seen something of the truths of psychology and with a determination to be fair to the worker. Some of its exponents, while developing their schemes apparently chiefly from the employers' point of view, have been anxious for the up-rise of labour, and began their studies with the intention of helping labour. In fact, as I hope to show, labour has been a little foolish in standing aside, for out of the theories of Scientific Management something greater might have been evolved and the many inductions and observations and studies might have been put to good use. So in this paper I shall attempt to examine the principles of Scientific Management quite dispassionately and rather with the intention of discovering what better use could have been made of those principles if they were applied in what I would call a mutual spirit.

The origin of Scientific Management, or at least the earliest trace which I can find of it, appeared in 1867 in connexion with the United States Cavalry. In preparing the instructions which were issued to the men in connexion with the grooming of horses some careful study was given to the subject and the most precise results were obtained as to the way in which the grooming might best be done, not only to be most efficient, but also to involve the least expenditure of labour. Later on various labour operations were tackled in the same spirit. We have records of them in Taylor's books and Gilbreth's. Later still the psychologists entered into the same field and studied *mental* operations as precisely as the exponents of scientific management had studied physical operations. This of course carried the movement more widely afield, so that it included the methods of co-ordinating the supervision or the immediate management. Out of all this there grew up what are called Efficiency Engineers, and there has been a wonderful mass of writing on the subject. Let me say at once that three-fourths of the writing on this subject is the sheerest quackery. We shall try in our studies to keep to those writers who really have made a contribution of value in that they have given precise and careful study to this or that factor on industry. For the quackery is easily separated from the worthy research.

Englishmen generally think of Scientific Management as a means whereby a clever American decided which was the most convenient shovel for a gang of navvies to use. It is this—and very much more. It is really a minute system of detailed functional industrial process. It begins with planning, and planning is carried out to rigorous details. The task of each workman is carefully thought out; each motion is studied and considered, and he is taught that method of carrying out each operation which is easiest and is most effective. The planning is separated from the operation and is vested in a different person, an expert, so that the workman is relieved of a certain amount of intellectual operation in connexion with his physical operations. The actual physical operations are divided functionally on the ground that each workman will perform them more efficiently if he is a specialist. An elaborate system of instruction cards is introduced, and each workman is thus able to know what is expected of him and is graded for remuneration accordingly. All these processes are the subject of minute study; even the cinematograph is brought into operation to study the movements. There are time studies and motion studies. There are heaps upon heaps of records, in fact, Scientific

*Paper read before the London Telephone & Telegraph Society. Copyright of Sir Isaac Pitman & Sons, Ltd.

Digitized by Google

Management comes near to the old Red Tape and literally pleads for more and more records. There are studies of fatigue. There are adaptations of psychological methods for the purpose of impressing the staff, and great care is taken to take the staff into full confidence after the methods have been adopted. Then superposed upon this foundation of elaborate detail there is a precise system of functional supervision—a separate "Speed Boss" a "Discipline Boss," a "Time Boss," and other officers who, being adept at the particular tasks, are called upon to give model exhibitions of the best way in which each task is to be done, and to co-operate in the further study and analysis of the operations. Thus in Mr. Gilbreth's studies of brick-laying, the time of each operation is recorded and summarised, and methods of laying so many bricks, each with its appropriate mortar, are not only suggested but insisted upon. Then there is a very complex and thorough method of training, and even men who have been a long time at work and have acquired imperfect habits are sent back for training. Added to this is what I regard as one of the most valuable features, the publication of data showing the costs of production at each stage. Mr. Crowther in "Common Sense and Labour," deals with this point admirably. "As far as the workers are concerned, industrial representation is of value in the degree that it makes them familiar with the processes of the business and incites the creative instinct." The final characteristic is the method of rewards and incentives which is based upon the principle that not only do they recognise and reward the highly successful worker, but they recognise the earnest efforts of those who are not so skilled and not likely ever to be so skilled. I have stated the position as fairly as I can, but I cannot refrain from saying that in my opinion, Mr. Zimmern is perfectly right when he sums up Scientific Management as meaning that the management is to do all the thinking and the workmen all the toiling.

This in outline is the system. Its enthusiasts make very inclusive claims for it, and they bring evidence of its popularity with the workers. There is other evidence, however, and it is not readily to be laid aside. It is claimed for it that it encourages greater interest on the part of the worker, that it produces better men as well as better work, that it rids the worker of that inertia of conservatism which we all know to be deadly, that it introduces a healthier spirit of co-operation and fellowship, that it gives exceptionally good chances of promotion to those men who have qualities for being teachers, or research students, or one of the functional "bosses" to which we have referred. All this is to be placed in the foreground if we are to do justice to the system, especially if we think, as I think, that it has some contribution to offer to the world of industry.

In coming to examine the principles it is to be questioned at once if any such system can succeed if it seems to be imposed from one side. It is not always the case that objective study can discover the best means for each individual of doing any particular task. Take for example the pen with which I write. It might be the case that if I point the pen to my shoulder and use it with two fingers comfortably I could write better and more easily. But that does not include all the factors. There are subtleties of the strength or the weakness of particular fingers and even greater subtleties of nerve centres, and one can hardly believe that long usage with a tool like a pen does not evolve, by the natural process of finding the least line of resistance, the best way for me of using the pen. Of course there are fundamentals. We must learn in playing the pianoforte to produce the notes by five fingers in that way which long experience has taught us is the best, but one could hardly tell Paderewski to sit 9½ins. from the keyboard and hold his elbow half-an-inch above it. As in so many other things the expert, when he is expert, evolves his own rules and becomes independent of the processes through which he has passed to expertness. His expertness *is* independence. His experience leads him to change his posture from time to time and some of the postures to which he changes cannot be regarded as those which objective studies, even aided by the cinematograph, would decide to be the best.

A similar criticism may be urged from the psychological point of view. It may be efficient on the whole to take from the worker the mental operation of "planning," but if it means that we lose the mental effort by which the worker weighs up his task and considers the best means by which it is to be done it will not all be for advantage. I am reminded of a telling phrase in Norman Angell's "The British Revolution and American Democracy."—"The very fact that we do need more and more unity of action in order to make a large population with many needs possible at all, is the reason mainly which makes it so important to preserve variety and freedom of individual thought." The more highly organised and therefore the more closely-welded the social machinery becomes, the more important is the operation of individual thought and the more necessary is the widest freedom of thought. Already the development of industry has specialised the manual operations until the worker is given in many cases only a comparatively small and routine task. Adam Smith's account of the division of labour in respect of the making of a pin will be remembered. But it will be infinitely worse if the mental operations are equally specialised. Professor Marshall went shrewdly to the point when he said that it will "diminish the need of the operatives for resource and judgment in small matters." Nor is it quite true that mental operations are better performed if they are narrowed. The mind may become more efficient in respect of a particular operation if it is confined to that operation, but there is a false analogy between mental and manual operations. The mind needs variety in its work. It is not necessarily desirable that management should "eliminate other thoughts," for it may not be true that they have "a tendency to retard the work." There is something depressing in Dr. Wilson's article on the shell-shock men, where he says that the best man in the trenches was the man who had cut off all mental visions from the outside world. It is not necessarily the case that the mind is more efficient from the lack of interfering interests. One of the best psychologists of the past generation always stated that he worked better amid distractions, that his mind was more alert when he had to bring it, by a deliberate act, from wandering. Extraneous aids, such as the banishment of other noises or allurements, do not help the mind as much as we suppose, and many of us have discovered that we can concentrate better where there are interruptions than where we are given what seem to be the perfect conditions of quiet. If every task is to be planned scientifically by an expert planner and then given to us to perform according to that set plan we lose a valuable mental exercise, and it is questionable if the ultimate apparent efficiency which follows is not at too great a cost.

Further, in the psychological realm, it is at least doubtful if we can banish all the traditions of past generations by a plan of operations, no matter how ably schemed. Research to-day seems to indicate that in the sum total of our minds the contribution of to-day is very small in proportion. I daresay you remember Mr. Kipling's "The Finest Story in the World" with its account of the man with the memories of the Greek galley-slave in his mind. We all have such memories. The long chains of traditional modes of thought have a strong grip upon us. We cannot begin *de novo* in each generation. It may be the case that Mr. Gilbreth's method of laying bricks is far more efficient, in the matter of brick-laying, than the methods which have come down to us, though there is this to be said for those methods that they cannot altogether be wrong as they are the result of generations of experience. In introducing the "packet" system, Mr. Gilbreth has to face this tremendous inertia. Consequently it might seem that the most scientific management would build upon the traditional foundations, would modify them here and there, rather than attempt a bran new method which may be violently opposed to the methods of the past. Evolution seems to me to point in a different direction.

Again, though it is true that Scientific Management does set out to consider the worker, it does not set out to ask the worker to co-operate in discovering the new methods. He does co-operate as an individual; he does make his own records of times and of motions, but those records are taken by the experts and turned into data. It is not conceivable that by these means we should re-introduce zest into work and it is zest which is needed. If it is to the interest of the worker that newer methods should be introduced it would also be to the interest of the worker that he should take some part in the adoption of those methods, and their introduction will have a greater momentum in their favour from having the stimulus of this consideration behind them. It is just at this point that Scientific Management has failed to carry the workers as a body. They feel that Scientific Management is imposed upon them. "Industrial efficiency," says Professor Jones in his "Social Economics," "depends largely upon the spirit of the workshop. Without the hearty co-operation of the workers the most powerful mechanical appliances and the most efficient organisation are of no avail. One of the most serious errors of many who advocate Scientific Management is to believe that men can be parcelled out like bales of cotton, the appropriate muscles being employed in the most economical manner without reference to the volition of the workers." There is a further danger, too, lest the elaborate methods used in finding what may seem, at the moment, to be the best way of performing certain functions, should, by their very elaborateness become concrete and rigid, this very elaborateness making us hesitate to change them. Moreover, it focusses attention on the actual physical process and to some extent diverts attention from more suitable methods of research. As Mr. Fleming puts it, "Development has been limited in many factories working under Scientific Management to increase in quantity of those things already manufactured." "The work of industrial research is not sufficiently stressed by efficiency experts." It is an odd irony that in spite of all that has been said as to the advances due to Scientific Management it should include a danger of such a firm establishment of a particular form of practice as to become ultra-conservative. We have learned to be so facile in the use of instruments that they have become a part of us. We speak of the machine as part of us thus: "I go on my bicycle"; I do not say that the bicycle goes. Scientific Management has the psychological disadvantage that it introduces a new hiatus between the man and the machine. It would bid the cyclist consider the exact position of the ball of his foot when he wants to enjoy the cycle ride.

The group-mind naturally regards Scientific Management as being part of this process, and there is no means of effecting any improvement in industrial method without carrying the group-mind with us. This initial psychological inertia which Scientific Management has to face may be due to prejudice or to ignorance, as its supporters would contend, but it is a very real and hard fact. Occasionally we owe it to one of the experts that a revelation is made. For example, one of them has said that "for the purpose of productivity a man who represents the ox in his mental make-up is the best" The instinct of the worker for all that is not naturally or normally opposed to easier methods, to more facile motions, to the elimination of wasteful effort. His instinct makes him wish to think, or, as Professor James puts it, "between all the details of his business, the power of judging will have built itself up within him." There is some sound psychological reason why efforts to discover easier methods and more facile motions are met with prejudice, and this reason can be found, I think, in the fact that before we introduce such methods we must have the group-mind with us, we must take long traditions into account. There is a last objection, and that is that Scientific Management pays far too little attention to what one might call the art of work. The instinct of a worker gives him a lack of respect for the mere product. There is a yearning for style or for beauty. There is truth in what Mr. Galsworthy

Digitized by Google

said, that if we go on producing without regard for beauty we shall go downhill. It is of no avail that we produce with minimum effort. Rather if what we produce is a matter for pride there is greater pride in the greater effort. There may indeed be truth in the criticism that there may be too much ease, too much facility, so much indeed as will lead to that dulness which is the breeding-ground of discontent. The truth is that human nature is too complex for the crude Scientific Management. It can focus many aims under the one aim, for all the contents of the mind are by no means revealed when we take observations, even by a cinematograph, of industrial operations. "Zola," says Professor Stout, "recalled odours with great ease and distinctness. For him almost every object had its distinctive smell." He did not cease writing in order to smell efficiently. In all these respects there is an amazing difference between individuals. Some men visualise words when they hear them. Many of us use the familiar sight of words to check our spelling. Many of us live with a flood of memories raised by the words which we use. Be the instruction card never so scientific it cannot include all that passes through the mind of the worker to whom it is given as a guide. The workers know that there are various "ways of writing tribal lays, and every single one of them is right." It was Montaigne who declared that one who viewed Mother Nature in her full majesty and lustre might perceive so general and so constant a variety that any individual and even the whole kingdom in which he happened to live must seem but a pin's point in comparison.

These may seem to be destructive criticisms, and yet it has to be said that there is much to learn from Scientific Management. It has revealed to us that there is an enormous waste of human operations. It has revealed to us that even the simplest task is capable of scientific study, that, in truth, there is no such thing as unskilled labour. Thus its primary value, I think, lies in the light which it has thrown upon industrial training. It is probably the case that training for every industrial occupation needs to be made far more scientific. In all callings we need a day-by-day study of human operations to see if improvements can be introduced in the training of the next generation. I would have a committee on training in every industry, reporting month by month on their observation of the working and setting out with the particular intention of improving the training. We can learn from Mr. Parsons' account of what is done in an American industry,—"All the work of new or unskilled operators is inspected after each operation. This tends to prevent large losses by pressing home to the unskilled worker that what he is doing is important enough to be given attention by those higher up. The same investigator always inspects the work of the same men, determines the cause of wastages, and works out a proper remedy." If we interpret this as losses both to the worker and to the employer we can see the advantages. Uncomfortable positions can be acquired by habit, wrong motions may be adopted, and the discovery of these defects may throw light on the methods of training. In some cases it will be quite possible, still having regard for the empirical results which long tradition has brought to proficiency, to introduce changes straight away. In other cases it will be frankly realised that such changes can only be introduced, and possibly then not completely, in the next generation. If we set out in this way to develop Scientific Management we need not apprehend the hostility of the worker. He will realise that these studies are being made directly in the interest of his calling. It will modify the whole doctrine of incentive. To increase productivity is that at which all would aim, and hostility to that course more frequently comes from economic fears than from any other reason. I may quote Dr. Taylor's description of the Towne-Halsey plan. "It consists in recording the quickest time in which a job has been done, and fixing this as a standard. If the workman succeeds in doing the job in a shorter time, he is still paid his same wages and in addition is given a premium for having worked faster, consisting of from one-quarter to one-half the difference between the wages earned and the wages originally paid when the job was done in standard time." This is objected to by the votaries of Scientific Management on the ground that it does not rest on precise scientific time study, and that as neither management nor men can guess what will happen it leads to bad organisation. This, to my mind, comes near to the truth, if by good organisation is meant organisation which is itself sound and carries the good-will of the main body of the staff.

This reaction of practice upon training will undoubtedly have its influence upon practice itself. The discovery of a new means of laying bricks, to take Mr. Gilbreth's case, cannot be adapted to the training of the bricklayers of the future without having some attractiveness to the bricklayers of the present, with the striking difference that they will adopt it because they like to adopt it and because the traditional inertia has been weakened by that attractiveness. If it is true that study and synthesis of bricklaying discovered a method which required only 1.75 motions to lay a brick instead of 18 motions then it does not need much persuasiveness to get the worker to adopt it. Thus we face one of the stumbling-blocks which are in the way of Scientific Management so-called. We set out on a course which will develop in time, and this is a thousand-fold better than a course which, with all the tenderness and tact in the world, is yet imposed suddenly. There is no limit to what might be done by motion-study and the like if it is done with the attractiveness of good-will behind it. Here we may quote from Mr. Gilbreth's book on "The Psychology of Management," "This giving of the 'why' to the worker through the system, and thus allowing his reason to follow the details, should silence the objections of those who claim that the worker becomes a machine."

Such a machinery as this might well take the place of the "Speed Boss" and the "Gang Boss" and the "Repair Boss" and the multitudes of Inspectors. I do not see how anyone short of being an archangel could bear the official title "Speed Boss" and carry with him those who are to be speeded up. I am sure it is true that Scientific Management does not intend him to "speed up" at the cost of those who are speeded up, but evidence on this point is difficult to find and is not all in accord. It is intended that the "speeding up" shall be the result not of mere pressure but of easier and more facile operations. It is true also that universal standards are not drawn up, but it would be exceedingly difficult in a large industry to allow for all individual aberrations from the standard. The application of Scientific Management which I would favour would remove this danger, since it would operate from within and would develop by its own attractiveness. The "Speed Boss" would vanish and in its place would be a research and study committee always ready to guide and inspire the methods of training. But here again in the functional supervision there is much to learn from Scientific Management. It has put discipline on a new footing in allotting it to a functionalised officer, whose mission it is to encourage improvement rather than to penalise shortcomings. It has shown us light on vocational studies, in the selection at the outset of their careers of suitable persons for the tasks. It has taught us valuable lessons on organisation in the use of Instruction Cards, of carefully delimited responsibitities, of the encouragement of education both in the craft and in general knowledge, of the minute studies of fatigue and rest periods, of the use of leisure and amusement. We can afford to smile at its jests as the old type of management and at such stories as that which tells of the manager who came to the place where seven men were working and said "half of ye come along to another job."

But while we learn these lessons it must be from another point of view. Functionalisation may rob the employe of the most precious of all things—his initiative. I quote at this point a pretty little parallel from Mr. Graham Wallas' book, "The Great Society": "One sees the girls from an orphanage file along the street. Each girl walks by a companion, not chosen by herself with all the painful-delightful scheming of girlhood, but by the tired mistress, who gives a general order that the girls nearest to each other in height should walk together. They all wear clothes and boots and carry umbrellas of the same pattern. A uniform hat-ribbon may be necessary for recognition and discipline; but one feels that if each girl had chosen her necktie and umbrella, even from a dozen equally cheap patterns, both the choosing and the wearing would have been a source of positive happiness." We want rather to be passive encouragers of study and interest, of welfare and education, of leisure and amusement, rather than the initiators of it. In modern management there is the definite danger of trying to do too much. It is the heresy of to-day. It affects our methods of education, our charities, our politics, our economics. To this end we have devoted a rich wealth of study and research, and to this end we have ransacked the world for enlightenment. But we have brought this enlightenment up against the long tradition of inertia, vitalised by another long tradition, the tradition of having things done by others. The whole method of scientific planning, which is the characteristic of Scientific Management, is open to this criticism. Even scientific organisation runs this danger. It is possible to over-organise, leaving too little to the stimulus of individual spontaneity, and bringing men of varied abilities and temperaments too near to dead-level-dom. The highest organisation deliberately recognises what may be called its legitimate deficiencies and indeed leaves a certain place for gaps in its machinery, simply because its machinery is human and cannot be as complete as a system of belts and cog-wheels without robbing humanity of its most precious qualities. It is paradoxical, but nevertheless it is true, that a perfected organism calls for positively imperfect human units, and that as we improve the human unit in intelligence, we demand elasticity and adaptation in the organism. If we could make scientific processes in industry the occupation and the interest of those themselves who are the workers in industry there is no detail in the whole scope of Scientific Management which might not be brought into use, though into transformed use. Efficiency is an excellent aim, if the aim proceeds from within, and if it realises that true efficiency always looks back on itself and sees its inefficiency. It is of less value if it is superposed from above as a hard mould into which the individual must force himself. It is an odd thing that Scientific Management always ignores the higher management. In the sense in which I support it and advocate it the beginning must be made at the top. It is easy to overlook one's own deficiencies. It is perilously easy to sit in the seat of scornful criticism. If we are to cultivate efficiency from within, urged by an inner motive which will have the sanction of the collective consciousness of all within the industry, that efficiency must characterise the chief director as well as the humblest messenger boy. If it is to spring from an inner motive in the case of the messenger boy it must spring from an inner motive in the case of the chief director also. The day has long gone by when the head of an industry leads a life of gentle leisure, touching the industry now and again with finger tips. The day has gone by for anything in the shape of absentee control or occasional control, or distant control. It is not surprising that in America protest is most vociferous against this particular evil. The day is coming when science and method and psychology must be applied to the whole body corporate of industry, and that day will begin when the leaders realise that in their own methods they must find that efficiency which will inspire the methods of all whom they lead, that they must apply it with continuous zeal and steady and persistent effort, that they must manage themselves without being cumbered by detail, and have a clear mind ready for the just consideration of each problem. It is difficult to achieve, for there is the human factor in management as in other aspects of industry, but if it is achieved it will lead an example which is of more value than precept and will be able to bring the same spirit to bear in all the work of the industry. This, and this only, is the foundation of true Scientific Management.

THE TELEPHONIC DEVELOPMENT OF THE WORLD AT DEC. 31, 1919.

By W. H. GUNSTON.

(*Continued from page 53.*)

NORTH AMERICA.

The number of telephones in North America reaches the enormous total of nearly thirteen and a half millions: of these 12,668,700 are in the United States. According to the 1919 report of the American Telephone and Telegraph Company there were:—

"Bell" owned...	7,739,159
"Bell" connected	4,056,588
Independent companies (not connected with the "Bell" system) about	873,000
	12,668,700

Over 90 cities in the United States have upwards of 10,000 telephones.

Canada has 724,490 telephones, of which 314,855 are in Ontario; 119,765 in Quebec; 58,379 in British Columbia; 70,256 in Saskatchewan; and 57,959 in Manitoba.

There are 75,033 stations in Toronto; 62,622 in Montreal; 34,397 in Vancouver, and probably well over 20,000 in Winnipeg, but recent figures for the last city are not available.

No recent information is available respecting Mexico or the various States in Central America and the West Indies, and recourse has been had to American estimated figures for these countries.

NORTH AMERICA.

	Telephones	Population (Millions)	Ratio
Canada	724,490	8.5	11.7
United States	12,668,700	103.5*	8.2
Mexico (estimated from American sources)	42,000	16.	381.
West Indies „ „ ...	27,000	—	—
Central America „ „ ...	7,000	—	—
	13,469,000	131.	9.7

* For 1918.

SOUTH AMERICA.

The only information obtainable respecting this Continent is that supplied by the River Plate and Monte Video Telephone Companies. American figures for 1914 relating to the various States have therefore been adopted with slight increases in each case. The development of South America is in the hands of numerous private companies, and complete and accurate information is difficult to obtain.

SOUTH AMERICA.

Chiefly from an American Source (1914).

	Telephones	Population (Millions)	Ratio
Argentine (74,296)	85,000	—	—
Bolivia	2,500	—	—
Brazil (39,133)	45,000	—	—
Chile (19,709)	22,000	—	—
Uruguay (13,599)	15,000	—	—
Peru	4,000	—	—
Venezuela	5,000	—	—
Other States	6,500	—	—
	185,000	38	208

AUSTRALASIA.

Australia.—The number of stations in 1919 is as follows:—

New South Wales	88,963
Victoria	62,738
Queensland	27,210
South Australia	18,526
Western Australia	12,218
Tasmania	6,275
	215,930

Sydney has 54,831 telephones; Melbourne 44,003; Adelaide 14,023; and Brisbane 11,869.

New Zealand has 78,110 stations, of which 9,158 are in Auckland, 9,395 in Wellington, and 7,625 in Christchurch.

AUSTRALASIA.

	Telephones 1918	Telephones 1919	Population (Millions)	Ratio
Australia	197,610	215,930	5.5	25
New Zealand ...	—	78,110	1.2	15
		294,040	6.7	23

THE WORLD.

	Telephones.
Europe	4,886,000
Asia	466,000
Africa	70,000
North America	13,469,000
South America	185,000
Australasia	294,000
	19,370,000

THE DEVELOPMENT OF LARGE CITIES.

Eighty-six of the cities of the world contain upwards of 20,000 telephones each. Of these 30 are in Europe, 2 in Asia, 2 in Australia, 1 in South America, and 51 in North America; or by countries, 47 are in the United States, 13 in Germany, 5 in Great Britain, 4 in Canada, and 2 each in Australia, Japan, Russia, Holland and Sweden; France, Denmark, Norway, Austria, Hungary, Poland and the Argentine have 1 each. The figures given for Petrograd and Moscow (those for 1916) are, of course, very questionable ones, but it is hardly likely that the number of telephones in those cities has gone below 20,000.

It would serve no useful purpose to calculate the ratio of inhabitants to telephones in each country. For one reason, the census figures are all old in Europe, whilst in America late estimated figures of population have been furnished; and for another reason, it is not known whether in foreign cities the telephone areas correspond with the Municipal boundaries.* The results of the first 10 towns in the list are as follows:—

1	New York	8.5 inhabitants per telephone.
2	Chicago	5.4 „ „ „
3	London	23. „ „ „
4	Boston	6.5 „ „ „
5	Berlin	11. „ „ „
6	Philadelphia ...	9. „ „ „
7	Paris	20. „ „ „
8	San Franciso ...	4.5 „ „ „
9	Stockholm	3. „ „ „
10	Detroit	7.9 „ „ „

* For example, the telephone development of the county of London is 270,000 stations or 1 to every 16.7 inhabitants.

Glasgow	...	40,963	*Memphis, Tenn.	...	18,675
Charlottenburg	...	39,693	*Dayton, Ohio	...	18,408

* The figures for these cities are those only of the Bell Company. An addition of at least 10 per cent. must be made to allow for the Independent Companies' stations. They refer to the end of 1918.

Altogether there are 179 cities in the world each possessing upwards of 10,000 telephones. They are distributed as follows :— United States of America, 91 ; Germany, 21 ; Great Britain, 12 ; Canada, 9 ; Japan, 5 ; Australia, 4 ; Sweden, 3 ; Netherlands, 3 ; Switzerland, 3 ; France, 2 ; Italy, 2 ; Russia, 2 ; Austria, Czecho-Slovakia, Hungary, Denmark, Norway, Belgium, Poland, South Africa, Brazil, Argentine, Uruguay, and Cuba, 1 each.

NOTE.—Since last month we have received official figures with regard to the Netherlands which had 146,416 telephones at the end of 1919, of which 28,157 were in Amsterdam, 23,073 in Rotterdam, and 19,831 in The Hague.

TRAFFIC SECTION DINNER.

A very pleasant evening was spent by members of the Telegraph and Telephone Traffic Section and their guests at the Holborn Restaurant on Jan. 12.

As this dinner was of the nature of a family gathering, the speeches were few and informal. Mr. John Lee proposed "The Telegraph and Telephone Services," which was acknowledged by Mr. Dalzell, and the toast of "The Ladies," proposed by Mr. W. D. Stewart, was replied to by Mrs. Trayfoot.

The remainder of the evening was spent in social intercourse, interspersed with a few songs and some "White Magic."

Practically every member of the Section was present, and the evening was voted to have been such a success that it was decided to repeat the experiment annually.

TELEGRAPHIC MEMORABILIA.

As one writes the daily press is full of the wonderful results of the Marconi Wireless Service between London and Paris *via* Witham and Chelmsford, and as a temporary expedient during a period of specially abnormal conditions where excellent means of cable communication are simply rendered nugatory by forces over which this country has little or no control, one can only congratulate the British and French public upon the feat. The writer may possibly be criticised for not receiving the announcement with unbounded enthusiasm, and the reasons for this lukewarmness are not far to seek. In the first place despite the success of this particular wireless installation to deal with a certain amount of traffic expeditiously, there yet remains to be seen the exact total of daily messages dealt with between the two capitals by this method. It is by no means an unique feat to exchange an individual message or two between two points a hundred miles or so apart in a matter of minutes. Both the private companies and the British administration have accomplished that feat repeatedly and are daily repeating the operation by means of their Atlantic cables. What, however, neither of them have yet been able to do, is to deal with a rush of hundreds and even thousands of telegrams without delays running into hours. In this direction wireless has its limits well within those which are available to both long and short distance cable telegraphy. One welcomes every advance of telegraphy in whatever direction developments may finally decide, but those writers in the daily press who lead the public to expect so very much from telegraphy without wires are more likely than not to severely discount their own value as prophets by reproducing but one side of the facts.

A temporary wireless communication was opened between this country and Italy, the home of Marconi, yet after transmitting about a dozen telegrams and waiting more than twelve hours London was informed that the Italian office had not received them, and they had to be re-transmitted. Up to the time of writing these lines, the daily results have been equally unsatisfactory. Improvements will most certainly come, but in the *Proceedings of the Institute of Radio Engineers*, August, 1920, it was stated in connexion with the possibilities of developing a large commercial traffic that "experience has shown that the most suitable wave-lengths for trans-oceanic communication lie between 12,000 and 17,000 metres," and that further, "This space in the ether has already been taken up by five first-class transmitting stations," viz., American two, and British, French and German one each. "By widening the wave-length range down to 10,000 and up to 20,000 there would be room for seven more first-class stations," or a total of twelve for the entire habitable globe. Mr. G. F. W. Alexanderson, who gave this interesting information to a meeting of the above institute, went on to say :—

"One advantage of such a station is that its message can be received all over the world, but this implies that for full utilisation it must have world-wide 'right-of-way' for its wave-length. The present rate of transmission from these stations is about 20 words a minute, thus it seems obvious that the capacity of radio is quite inadequate to handle any considerable portion of world communication. This, however, is a pessimistic view, and does not take into account technical possibilities of improvement, such as :— (1) Increase in transmission speed ; (2) improved selectivity based on wave direction ; and (3) closer spacing of wave-lengths permitted by (2)." Some recent progress on these lines is referred to, and it is stated to be probable that the average transmission speed will before long be 100 instead of 20, that selectivity for direction will quintuple the number of stations operable on one wave-length, and that 1 per cent. intervals in wave-length will be practicable instead of 7 per cent. as at present. Thus an optimistic outlook indicates a multiplication of present capacity by 175. "The transmitted wave must be a continuous wave without objectionable components outside the limits of ½ per cent., subject to certain fundamental limitations which are explained. . . . Closer spacing of wave-lengths has great possibilities. Selectivity with reference to wave-length can be greatly increased by several successive tunings in either the radio, the audio or some intermediate circuit. It is shown that high-speed telegraph signals assume to some extent the objectionable characteristics of a spark signal."

This interesting, well-balanced and scientific view is placed before the readers of the T. AND T. JOURNAL (through the kind medium of the *Technical Review*), not that my fellow-craftsmen should feel too complacently concerning the future of telegraphy by means of wires, but that an opportunity should be given of weighing up something of the real future possibilities of telegraphy *without* wires, its present limitations, the *pros* and *cons* as presented by competent engineers and the hopes and fears of these latter regarding their own particular speciality.

The disadvantages which at present militate against a more efficient cable service between this country and Paris would be inconceivable to anyone either inside or outside of the telegraph world, were they not in daily touch with the conditions obtaining. It is difficult definitely to locate the trouble, except that it is decidedly beyond the French submarine cable-head. At times London has actually worked better with Switzerland than Paris, though the same lines pass through the latter city. From private letters received, however, it is evident that the French administration is moving in the matter. Communications with Belgium, Holland and Germany have all materially improved, and approach more towards greater stability. There is something of cruel irony in the fact that communication with our nearest neighbour should lack that quality.

The annual meetings of the Eastern Telegraph Company and its associate company, the Western Telegraph Company disclosed some very interesting facts regarding these most successful private organisations.

Digitized by Google

The former company has expended £1,200,000 on additional cables between Aden and Bombay, and, while paying an excellent dividend to its shareholders, has not forgotten the social and other needs of its staff. The company has recently purchased "Meadowbank" at Twickenham as a club-house, together with 16 acres at Orleans Park. The latter as a recreation ground for the use of its personnel and their families, and the former specially, though not exclusively, for men home on furlough. The total cost amounts to over £50,000.

In addition it has taken over the whole of the liabilities of the Staff Pension Fund, and has contributed no less than £20,000 to assist and to place on an actuarial basis the Widows' Pension Fund, which had previously been run unaided by the staff itself.

The associated Western Telegraph Company has also been alive to future business. It has renewed about 1,000 miles of the original cable between St. Vincent, Cape Verde Islands and Pernambuco, and an order has been placed with the manufacturers for the renewal of the older portion of the Lisbon-Madeira cable. Additional cables are projected on the Brazilian coast between Pernambuco and Maranham, Pernambuco and Maceio, Victoria and Rio de Janeiro, and Rio de Janeiro and Santos, while additional facilities are to be given in future to Santa Catharina and Rio Grande do Sul. All these developments and activities are particularly satisfactory, especially as these companies being "domiciled abroad" in certain instances are not unlikely to have been adversely affected by rate of exchange. Incidentally, there does not appear to be any sign of misgiving as regards the future competition of "wireless," probably because the technical advisers of these concerns are well aware that cable telegraphy has by no means reached its limit in inventive progress.

It is announced with the greatest satisfaction that a total sum of over seventy pounds has been subscribed to the Benenden Games Fund by the C.T.O., including a very welcome donation from "one of ours," now retired from the service.

As the months roll on one is compelled to add to the tale of good men and true who are retiring, or who have retired from the Telegraph Service. Sometimes it is the tale of a happy warrior who leaves us apparently unscathed by the storm and stress of our craft, sometimes one records with sympathetic touch the withdrawal from active participation before the officially allotted span has been covered, sometimes, alas, it is the younger and apparently more vigorous who leave us—called hence.

Of the latter type, none came as a greater shock that the sudden death of Mr. Griffin, of the Cable Room, who passed away quite unexpectedly after an otherwise very successful operation. As a very helpful assistant to the Censors at the Press Bureau during the war he had earned the very special esteem of those who came into daily contact with him, while his cheerful disposition as a colleague was a particularly outstanding feature of his nature at all times and in all circumstances.

To the first-named type of record more happily belongs the retirement of Mr. J. Field, Assistant Superintendent of the C.T.O. "Josh," if he will permit the familiarity, and knowing his kindly nature one feels one's self already forgiven, was never petty, and well understood that affection of one's colleagues, which frequently underlies honest jest and badinage. His friends were glad indeed to note that up to the last hour of duty he still showed that vigour and vim with which his name had long been associated. Mr. Field entered the service as a learner at Brighton in December, 1874, and was appointed to the then class of Third Class Clerk at Ramsgate in 1875, and came to London a year or two later, passing through the various grades up to that above recorded. "Josh" was a personality in the C.T.O., and one which will certainly be missed. We shall never see his like again. He leaves us all the duller now that his vivacious cloak-room histories of the past prowess of past telegraphists, *and* past superintendents will entertain us no more.

To T.S. Foreign we next descend to place on record the somewhat premature retirement of Mr. W. Meyers, Telegraphist, whose failing health compelled withdrawal from as faithful service rendered to the State as State could well desire, for the *one* outstanding feature of Mr. Meyers' career was this, that he unfailingly gave of his best. The cleverest, the most assiduous among us could not do more. He was transferred from the late Submarine Telegraph Company in 1889 and leaves the Cable Room with a host of well-wishers behind him who placed on solid record, in the shape of a handsome clock, their keen appreciation of his worthiness.

Mr. G. W. Murdoch, of the old assistant superintendent's class, also left G.P.O. West towards the close of 1920. Of the North Country, concerning which he was always enthusiastic, he carried to the last day of duty something of the ruggedness of those latitudes, with a yearning for its rocks and hills. To Mr. Murdoch is accorded the kindliest of thoughts of all who know him best. May rest from official trammels and increased facilities for breathing the free air of heaven go far to renew the lease of life of G. W. M.

The C.T.O. has not received quite so many seasonal greetings from offices as was her wont in pre-war times, but one or two are particularly worthy of note.

Much appreciated was a list of autographs from the Secretary's Office addressed to the Cable Room bearing the names of former cableites, who, it is refreshing to note, have not lost their affection for the "old show!"

Of continental greetings, Paris naturally was first in the field with the most courteous of hopes and wishes, Milan, Rome, Genoa, Zurich, Bale, Berne, Geneva, Amsterdam, The Hague, Wellington, N.Z., Siam and Warsaw, following, while Berlin and Hamburg greeted us with the old-familiar *frochliche Weihnachten*. From another portion of the C.T.O. came a curious note, wishing the staff "an offensive Christmas and an offensive New Year." A somewhat meagre knowledge of Russian prevented an immediate appreciation of the kind spirit behind this attempt to compliment us in our own language. However, it was eventually decided that an "advancing" or "progressive" new year was the only desire of our well-wishers in the Arctic Circle. These same correspondents not long since, evidently by the aid of the same Anglo-Russian dictionary, requested London as follows: "Please repeat the threshold of the text of last message." A method of expression new to telegraphic lingo, but soon understood.

The engineers have not waited for the rebuilding of the Havre Office to complete the experiment of split Triple and Baudot duplex between Liverpool —T.S.F. and the French port, but have fortunately induced the latter administration, who have heartily co-operated, to transfer the trial to Paris.

With the latter city this trial has proved a complete success, so that there are now the following traffic channels working on the one wire between Liverpool, London and Paris:—

Liverpool—London	=	4 channels.
London—Paris	=	4 channels.
Liverpool—Paris	=	2 channels.

The late chief of the Antwerp Office, M. Collignon, well-known to many friends both at G.P.O. North and West, has recently retired from the Belgian Telegraph Service owing to the age-limit. Our respected friend is not content to rest entirely, but is devoting a few hours every day to a society devoted to the care of the blind. May he long be spared!

Mr. J. Munro, late of the Foreign department, sends greetings to all old colleagues, with best wishes for 1921, from Cairo, the headquarters of his present appointment as Principal Inspector of the Egyptian Telegraph Service. Our friend could not long give up his old love for we find him busy running a Service Literary Society, himself contributing a paper on "Medieval Mystery Plays."

An experiment is being made in the Central Telegraph Office with what is called "functional supervision." It is not necessary to give the full details at the present moment, but the central idea is to have in addition to the floor superintendents, who are responsible for particular areas in the galleries, certain superintendents who would be responsible for all the functions, and would co-ordinate the general control in the separate divisions. The experiment is beginning in a small way, and a "Plant Superintendent" has been allotted, whose function it will be to be responsible for the plant generally, and particularly for the high-speed plant, multiplexes, Creeds, &c., to keep them under review and to study the various improvements which are suggested from time to time, and also to govern the allotment of spares at times of need. It will be interesting to see how this experimental venture will affect the general supervision, and if it fulfils expectations in relieving the floor superintendents of special anxieties, it may facilitate the general supervision by the latter officials.

It must have surprised our French friends to learn that, twenty-two years after the introduction of the Baudot into England, we were asking ourselves—and them— how to manipulate and how to train in manipulation. The tardiness of the inquiry was, of course, due to the fact that the expansion of the Baudot system in Britain is still a recent development, so that the need for co-ordinated methods of training and of manipulation has but lately made itself felt.

Within the past year or two, however, interested observers had remarked the differences in style to be found among the Baudotists of any large office and between the general style of one office and that of another; whilst observers who visited Paris returned with the news that French manipulation was not quite like anything to be seen in these islands.

The necessity for defining good manipulation and laying down the lines along which instruction should proceed thus became apparent; and it was obviously as much to the interest of the operator as to that of the department that this need should be met.

A small committee of London and Provincial experts was therefore formed, and a careful census of opinion was taken in London and at several provincial offices. The conclusions arrived at were then compared with the views of the foremost French experts.

The results of the committee's work will be embodied in an official guide to manipulation and training, which will be issued as soon as possible. The aim of the committee was not the discovery of a method of manipulation which should give greater output; it was to find and to make known the style best calculated to afford comfort to, and least likely to entail strain upon, the operator. How far they have succeeded Baudotists will soon be able to judge for themselves.

The features of the style now recommended are, ease of seated position, freedom of action, and avoidance of fine finger movements.

The most revolutionary of their proposals concerns the method of training, and here the practice of the French instructors is adopted. For some time the learner exercises upon a keyboard unconnected electrically, using the keys merely as an aid to the memorising of the combinations; the idea behind this being, that once the combinations are "in the fingers," their formation in time with a cadence becomes a simple matter.

How our French friends arrived at this method of instruction—whether by accident or by a singular scientific up-to-dateness—is not clear, but it is certain that their procedure corresponds exactly with the most modern theories of the teaching of music and eurythmics.

It is not suggested that Baudot signalling falls within the same category as the above accomplishments; but, although it cannot become a thing of joy, it should at least be devoid of most of its present terrors when a freer method of manipulation has been generally adopted. J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

Telephonic Development.

Notwithstanding the serious delays which have taken place in the deliveries of stores by manufacturers, the District staff are able to look back upon the extension work carried out during the year 1920 with satisfaction. Actually, the number of direct exchange lines was increased by 14,372, which is equal to a 10.09 per cent. increase. These figures establish a record for the District, the previous highest numbers of added exchange lines having been 7,928 in 1913 and 10,931 in 1919.

* * *

Institution Meeting.

In the report of the Select Committee of the House of Commons on Telephone Rates a definite recommendation is made that the Research Branch of the Engineer-in-Chief's Office should be extended. From the tone of the report it is evident that the Committee was impressed with the value of the work done under somewhat difficult circumstances. All P.O. Engineers will heartily agree with the recommendation, and are glad to know that steps have already been taken to acquire a site and to erect temporary buildings in which the staff may be housed. There is no doubt that when the proper equipment is available and a sufficient staff of keen enthusiasts is employed on research there will be marked developments in telephone science. The results of their work will no doubt be made available to all P.O. Engineers through the medium of the I.P.O.E.E.

That much valuable work has already been done is evidenced by the paper on "Four-Wire Telephone Repeaters," which was read before the London Centre of the I.P.O.E.E. at the Royal Society of Arts by Messrs. C. Robinson, B.A., and R. M. Chamney, B.Sc., on Jan. 10.

The four-wire system is the outcome of experiments which have been made as a result of the application of the telephonic repeater to telephone circuits. It involves the use of one pair of wires for transmitting from the "Up" station and a separate pair from the "Down" station. At first sight this would appear to be a retrograde step, as hitherto one pair has sufficed for speech in either direction, and the tendency of late years has been to obtain as many channels as possible over one pair of wires. When, however, investigations were made as to the maximum amount of amplification that could be obtained by the use of repeaters in one pair of wires, the fact was revealed that the amount of amplification was limited by certain characteristics of the line and that if these limits were exceeded singing or echoing took place. A margin is also necessary in the amplification to allow for variation that may take place between the line and the compensating network, which is a feature of the system. This further reduces the permissible gain.

Experiments were, therefore, made to devise a system which would allow of greater amplification without the introduction of singing, and the four-wire system is the result. So far as the experiments have proceeded it appears that it is not economical to work in the four-wire system on circuits of less than 400 miles, but as the distance increases, especially if the wires are of small gauge, the advantage becomes apparent. A method of superposing a phantom circuit on a four-wire system was indicated. Considerable stress was laid upon the importance of providing lines which were absolutely uniform in their electrical qualities. The necessity for correct spacing of loading coils and the proper proportions of the windings of the transformers and other apparatus used was also emphasised. It is essential for the satisfactory working of telephonic repeaters that the conditions shall be quite stable, and it is evident that still greater attention will have to be paid in the future to every detail in the design, manufacture, jointing, testing, and maintenance of a cable system, and also in the design and manufacture of the apparatus to be used.

The authors described how the difficulties of signalling over such circuits had been overcome, although perhaps perfection had not been reached. In the subsequent discussion, Mr. Grinsted, of Messrs. Siemens & Co., described some interesting experiments which he had made in collaboration with Mr. Laidlaw in signalling over such circuits by using a frequency of 800 periods per second, while Mr. Ericcson, of the Western Electric Co., described some successful tests which had recently been made in America on circuits of 1,000 miles long, the conductors being of 20 lbs. copper. He ventured to prophecy that the time was not far distant when speech would be commercially practicable between London and Rome. No doubt the paper will be printed in due course, and it will be found to be worthy of close study by all those who are interested in the future of telephony.

The size of the audience and the close attention given to the paper and the subsequent discussion indicated how keen is the interest of engineers in matters relating to the improvement of speech over long distances.

* * *

Denman Chess Club.

An interesting tournament is now in progress, and some of the "experts" are having unexpected shocks. The leaders, at present, are Mr. Francis, "A" section, and Mr. Gardiner, "B" section. Two rounds of the "knock-out" competition have also been played. Interest has been well sustained, and the games are being keenly contested.

On Jan. 19 Mr. J. Kniager, of the Woolwich Chess Club, will give a simultaneous display against 15 players. Mr. Kniager, in a recent match in which Senor Capablanca met 40 players simultaneously, was the only one who succeeded in avoiding defeat by the champion, the result being a draw.

Query.

Will the officer in charge of the New Blackfriars Automatic Exchange be called a "Panel" doctor?

* * *

Obituary.

Many in the C.T.O., as well as in the Engineering Department, who knew Mr. A. E. Roberts, will hear with regret of his death which took place after a long illness on Dec. 9 at the early age of 48. Mr. Roberts left the Central Telegraph Office in 1900 and entered the Engineering Department as a Sub-Engineer. He was subsequently promoted to the rank of Second Clas Engineer. His early engineering experience was spent in the Metropolitan Districts, and at the time of his death he was attached to the Test Section of the Engineer-in-Chief's Office.

* * *

Presentations.

On Jan 13 in the workshop at the C.T.O., the Superintending Engineer (Mr. A. Moir, O.B.E.) presented Mr. F. E. Holman with the Imperial Service Medal. On Jan. 14 at the Paddington Exchange, Mr. Moir presented a similar medal to Mr. G. H. Gilby, Skilled Workman, Class 1, of the North-West External Section. On both occasions the Superintending Engineer in making the presentations, gave some interesting particulars in connexion with the history of the decoration, and referred to the long and faithful service of the recipients. Mr. Holman recently retired form the mechanics' shop in the C.T.O. Section. His service in the department covered 45 years and he has been a witness of many remarkable changes during this period. He also served for many years as a volunteer in the Royal 4th West Surrey Regiment (The Queens). Mr. Gilby's long connexion with the Engineering Department commenced many years ago at Yarmouth. For some time prior to his retirement he was attached to the Metropolitan District, where he was held in very high esteem, both on account of his personal and technical qualifications.

FROM A FRAGMENTARY MSS. OF THE ARABIAN NIGHTS.

and they lived together in felicity until their days were ended by the divider of friends and the terminator of delights. But, she said, that story is not so wonderful as the story of the Postmaster-General and the Ramp. And the king said: "What postmaster-general and what ramp?" And she said: It has reached me, O happy king, that in ancient times and former days and past ages there was a merchant amongst merchants, a postmaster-general by his calling, and it befel that when owing to the dearness of those times he found that he was not selling his merchandise at a profit, he said: "Ya Allah, I will raise my charges, even as the other merchants have done by reason of the hardness of these times." And he did so; but when the sheikhs of the merchants, and elders of the city, and emirs of trade heard of those charges they were enraged to the limit of enragement and frothed at the mouth to the limit of frothiness, and they said: "This is not merely a rise in charges—this is a ramp." And he said: "What then is a ramp?" And they said: "It is a deed of darkness done by a government department, but as to the deeds of private merchants in the same direction, they are the works of light." And he said: "But how then shall I prosper in my affairs and make a profit in my trading?" And they said: "Be that upon thee! Thy proposals are monstrous and out of measure * thou art as a miser hoarding up treasure * or a tyrant putting on the screw for pleasure *" And he said: "I have increased my charges but by four-fifths, whilst ye and others have doubled yours." But they said: "Hast thou not read what the scribes say of the Telephone Iniquity and the Telephone Scandal and the Telephone Tyranny? Hast thou not felt just indignation's burning flame * and art not overwhelmed with shame * and knowest thou not that the Volume of Opposition is growing daily?" And he said: I have perused that volume, but it seemeth not to be the work of the well instructed * but the dawn overtook Sheherazade and she ceased her permitted discourse.

But when it was the thousand-and-thirty-third night she said: It hath reached me, O happy king, that when the postmaster-general said to the merchants: "it seemeth not to be the work of the well-instructed," the world became black before their eyes and, enraged, they cried: "O son of the basest of dogs, we are thy largest customers, and thus we are precisely those by whom thou losest most heavily in thy trading. Wilt thou not therefore treat us with more consideration than the others?" And it is related that the postmaster was so struck by this appeal * that he pinched himself to know if he were real * and pondered their words some deal * and descended from the pinnacle of his obduracy * and repented of his contumacy * but Allah knows more—And, she said, this story is not so wonderful as that of the Railway Companies and the Doubled Freights and Heavily-increased Rates, and the Trains Overcrowded to Excess, and the Degenerate Express. But the king said to his soul: "If she relates any more such stories I will certainly put her to death." And he said: "Relate to me rather some fantastic and marvellous story." So she began to relate the history of the Jurywoman who knitted Jumpers.

The Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. FEBRUARY, 1921. No. 71.

THE CAMPAIGN.

THE Press campaign against the Telephone Service has been conducted with passion and not without unscrupulousness. It has hurled its angriest epithets against us and it has not hesitated to include garbled statements of percentage increases in charges and unproven assertions as to alleged inefficiency. On the minds of some of us the crusade has had an effect very different from that which was intended. We had looked on in sorrow rather than in anger, for we have had the advantage on this occasion of knowing the facts, and that knowledge does not increase our respect for the newspapers, either as the custodians of public opinion or as the repositories of carefully-analysed information. Others of us have been indignant. We have itched to write an equally angry reply. Day by day we know that the service which we are giving is excellent in quality. We know that men and women of all types of mind, among the manipulative and the clerical and the technical and the administrative staffs, are proud to give of their best in the service of the public. We know that this organised campaign, which each member of the staff must withstand in silence, is based upon the particular self-interest of a small section of the telephone community. We know, too, that in defending our cause we always run the risk of seeming to defend nationalisation as a theory—a theory which, as public servants, is not our concern. We have had to go on, doing our best, and bearing, meantime, all sorts of misrepresentations. At one time we are told that our salaries and wages are four-fold what they were before the war; at another time we are held up to reprobation as being ill-mannered, or slack in attention, or heedless of admonition, or positively malicious.

It is this personal aspect of the crusade with which it is as well that we should deal in this place. At least it has had the advantage of binding us all together. If the charges are pointed against those whom the staff regard as their leaders, in their implication they are inclusive of everyone in the service. The thousands who have come to us from the National Telephone Company are now included, though they must look back on the bitterness of campaigns in the 'nineties with something of a temptation to pinch themselves to see if they are awake. In those days, they are now told, they were marvellously efficient. To-day their souls are transformed. Of course, the writers of these angry articles and the proposers of fierce resolutions have not always thought out what they were saying. We live in "stunt" days, when strange opinions come from strange places, when one reputable institution demands that the telephones shall be handed back to private ownership and another demands that it is not necessary that the telephones should make a profit; when one writer says that the flat rate tends to keep down the number of engaged lines and another says that the advantage of the flat rate is the full loading of the line.

It is not pleasant to lose one's respect for newspapers, but we do not doubt that before that catastrophe happens the storm will have passed. The manufacture of public opinion is not so readily the result of "stunt" campaigns as is sometimes supposed. We counsel patience and trust, for the truth has a knack of making itself known, and usually these campaigns over-reach themselves. The public, being shocked daily, becomes at length too shocked to be shocked. It will find in the hour-by-hour efficiency and courtesy of the operators what, after all, is the best answer to the attacks. Each of us is the object of the campaign, and each of us has the weapon of defence. For every connexion of one subscriber to another conveys to the mind of the calling subscriber an impression either favourable or unfavourable to the service of which we are a part. In striving for scrupulous and detailed efficiency and for courtesy and consideration as the accompaniments to that efficiency, we shall be far more articulate than we suppose on behalf of the service. The reply to the campaign is in the hands of the staff.

HIC ET UBIQUE.

Apropos of our editorial last month we learn from an extract from the *Electrotechnische Zeitung* that the German Administration has also had to endure repeated reproaches from the daily and technical press for its backwardness in the introduction of automatic exchanges. The Administration's attention was drawn to a small Strowger exchange at the Chicago exhibition in 1894, and although no automatic exchange was then working in America, they contemplated the opening of a small 20-line exchange. When it was known in 1898 that a 20-line exchange was working in America and that another small one was established in England, the German Administration decided on a larger experiment with an exchange of 800 lines, but great difficulty was experienced in obtaining the plant in America. A 400-line board was put in operation in Berlin in 1900.

IN 1908, an automatic exchange was opened at Hildesheim. We remember the occasion well, for it was accompanied by much prophecy in the press of the early "disappearance of the hello-girl." Another was opened at Altenburg in 1910, and since then automatic exchanges have been installed at Posen, Dresden, Liegnitz, Leipzig local toll-line exchange, Halle, and some smaller places. Unfortunately, the extract does not inform us whether the whole system in these towns is served by the automatic exchange. A place

Digitized by Google

of the size of Dresden, for example, is probably served by several exchanges. At present automatic exchanges are under construction in Germany, which will serve when completed a further 50,000 lines.

THE telephone system of Warsaw, (like that of Petrograd and Moscow) was in the hands of a Swedish Company. We learn from the *Financial Times* that as a result of negotiations with the Polish Government, the concession for Warsaw has been extended for another twenty years, and in addition, concessions have been granted to the company for Lemberg and Lodz. The company will now supply service not only to the three largest cities in Poland, but also to the other principal towns. We understand that the State has an interest in the company.

THE *Spectator* says: "Every old subscriber looks back with regret to the days of the National Telephone Company, which gave the public a good service." Those numerous readers of ours who are old National men will agree that the Company gave a good service, but they will also remember that the Press of those days did not think so. The telephone service was then even more bitterly abused, if possible, than now. While the Press often forgets how many ex-National men are engaged in the present service; they also forget that many of them read the newspapers—and some of them have memories.

CAUSE AND EFFECT.

A CERTAIN evening newspaper boasts that it charged one firm £1,200 for one insertion of an advertisement. As the said firm advertises daily it can be readily understood that the cost of its goods to the public is artificially inflated by the newspaper ramp. The general public having to pay more for its necessities naturally demands higher wages, and in consequence the cost of goods purchased by the Post Office for its telephone system is increased. Its own labour bill is also increased in order that its employees may pay the prices demanded by shopkeepers which, as stated above, are unduly high on account of the immense sum paid in advertising. Incidentally, the public pays and has paid for some years 100 per cent. increase on pre-war rates for its daily paper. The P.O. faced with the increased costs of its labour and material purchases is compelled to call upon the users of the telephone service to pay more, but not 100 per cent. more, as in the case of the newspaper. The increased charges are to start two years after the Armistice and not two years before as in the case of the newspaper subscriptions. Incidentally, the following facts may be of interest:—

Old rates, 360 calls per annum—cost per call 4*d*.
New ,, 360 ,, ,, ,, ,, 7*d*.

Less than 100 per cent. increase in cost. For a greater number of calls the cost per call is reduced until at 500 calls it becomes 5*d*.

CORRESPONDENCE.

AUTOMATIC DEVELOPMENT.

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

SIR,—In your leading article of the January number of the JOURNAL it is stated that "All the larger Automatic Exchanges in the United States serve only a portion of the system of the towns in which they are installed, while the systems in Leeds, Portsmouth and other British towns are wholly automatic." This is unfortunately not correct as far as Leeds is concerned, as there are in this city five Magneto Exchanges with 3,005 stations. It is a great pity that your statement is not correct, as we shall, of course, not be able to reap the full benefit of the Automatic Exchange in the centre of Leeds until the other exchanges in the city are made automatic also.

T. B. JOHNSON.

Leeds, Jan. 20, 1921.

[Although the word "wholly" is not strictly accurate as applied to Leeds, our statement is substantially correct. There are 9,552 stations connected with Leeds automatic exchange, and according to Mr. Johnson's showing 3,000 connected with magneto exchanges. Those, however, are suburban exchanges, and we think it may fairly be claimed that Leeds itself is worked automatically. This is very different from the case of Los Angeles with 34,670 automatic stations out of over 130,000, and Sydney with 26,000 out of 55,000.—ED., *T. & T. J.*]

AUTOMATIC TELEPHONY IN LARGE AREAS FROM A TRAFFIC POINT OF VIEW.

BY M. C. PINK.

(*Continued from page* 60.)

The next diagram (Fig. 9) shows the switchboard arrangement on a call indicator position handling traffic incoming at a manual exchange from subscribers on an automatic exchange. It will be seen that there are four complete sets of digits (0 to 9) each one corresponding with one of the four digits of the required subscriber's number. There are *some* manual exchanges in America with five-figure numbers; and the additional figures on the left-hand side of the indicator are to provide for these in the special cases where they exist. On the top of the indicator (shown on a larger scale in

SECTION OF KEYBOARD OF INCOMING POSITION EQUIPPED WITH CALL INDICATOR

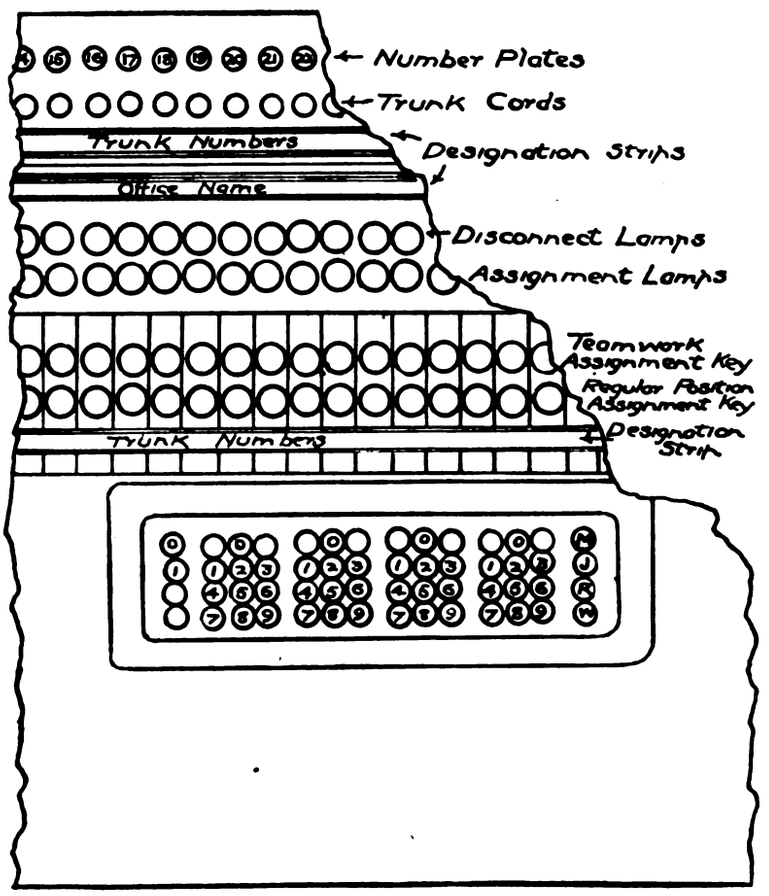

FIG 9

Fig. 10) is a ground glass plate under which the figures shown in the diagram appear. Under each figure is an individual lamp which, when lit, displays the figure to the operator. If an automatic subscriber requires connexion to, say, Holborn 1234, he dials HOL 1234. The impulses are stored in special apparatus at his own exchange, and this apparatus controls first the selection of a junction to Holborn, and then the storage of the subsequent figures, 1234, on apparatus which is automatically associated with the junction at the Holborn Exchange.

Digitized by Google

Assuming the junction to be number 16 in the diagram, the assignment (or calling lamp associated with that junction) lights, and the incoming operator at Holborn depresses her assignment key, which is the front key of the two shown. This act associates her position indicator with junction 16, and the figures which have been stored are then transmitted to and displayed on that indicator. The Holborn operator takes the plug associated with junction 16 and tests the number 1234. If she finds it busy she connects the junction to an engaged signal-jack. If it is free she plugs in. The ringing of the subscriber 1234 is automatic and the registration of the call is effected automatically in the same way as the registration of a call to *another automatic* subscriber.

CALL INDICATOR

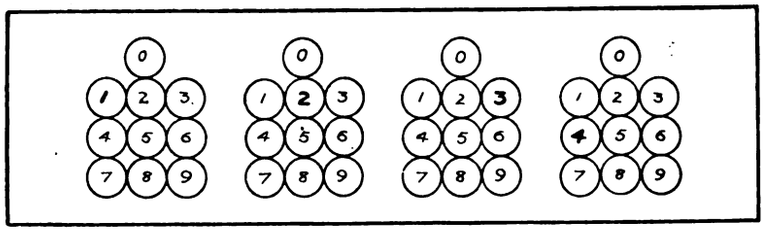

FIG. 10

When the caller releases the connexion a disconnect signal is received on the disconnect lamp indicated on the diagram 9. The incoming operator takes down the connexion and the junction is free to receive another call.

It will be seen from the diagram that a second key is associated with every junction. *This* key is to enable a neighbouring operator to associate her call indicator with the junction if the operator on the home position is otherwise engaged. This ensures a condition of team work which has not so far been introduced on normal plug-ended signal junction positions.

TANDEM CALL INDICATOR

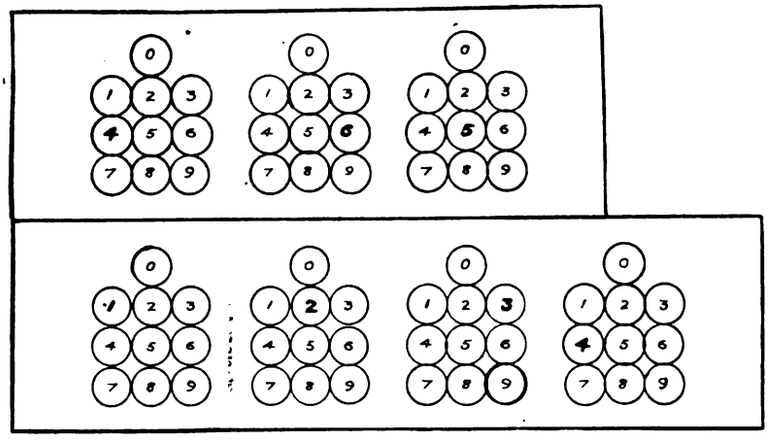

FIG. 11

In America the standard load for a terminal call indicator position without team work is 500 calls. With team work on a suite of positions a load of from 550 to 600 can be handled while ensuring a high grade of service. It remains to be seen whether similar loads can be worked to in this country.

Where the provision of direct junctions from an automatic exchange within the automatic area cannot be justified, the traffic for that exchange, together with that to other exchanges similarly situated, is aggregated and taken to a *tandem* call indicator position either at the home exchange or at some intermediate point from which the provision of junctions to the objective exchanges is justifiable.

It will be clear that this intermediate exchange may be handling the traffic for several small exchanges, and, in order that the operators may know which exchange is involved on each call, a special call indicator has to be provided.

This indicator is shown in the next illustration (Fig. 11). It will be seen that the indicator is in two portions, one portion displaying a three digit number only. This number is the code number corresponding with the letters which the subscriber has dialled as the code of the objective exchange. The tandem operator translates the code number into the exchange letter code and name, and proceeds to obtain the required connexion to the objective subscriber over the junction group available from the tandem point. The exchange code is usually displayed in red and the required number in green.

It is found in America that an operator at a tandem call indicator position can handle a load of 200 to 225 calls when the service from the "B" operators at the terminal exchanges is satisfactory.

MECHANICAL SYSTEM

REGISTRATION CONDITIONS TO BE MET

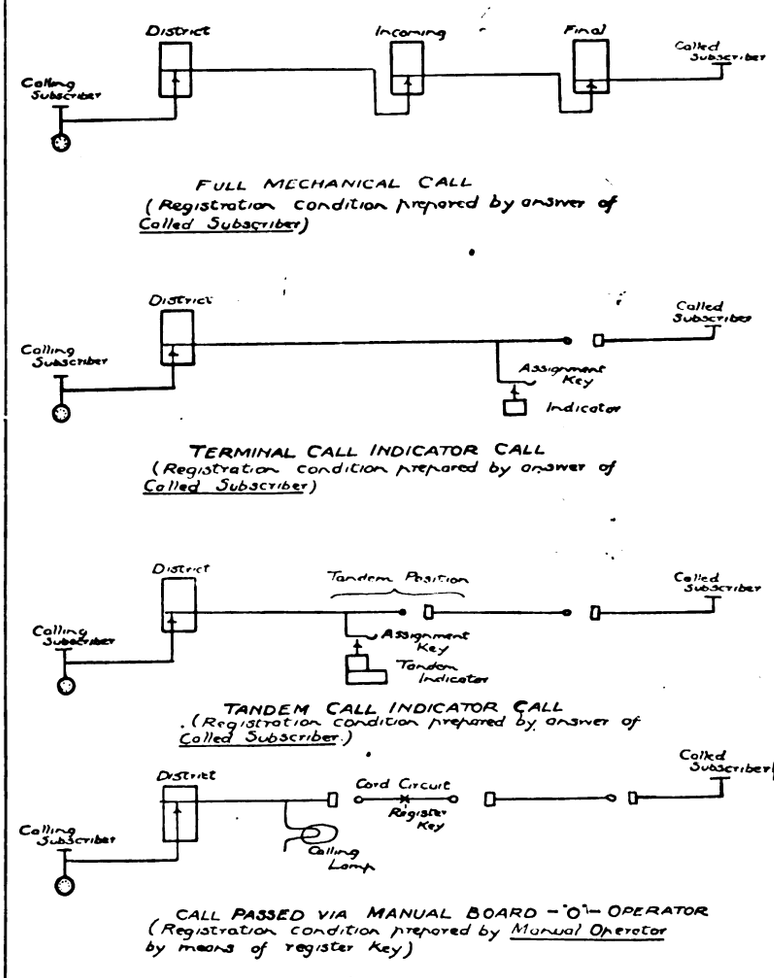

FIG. 12

In London the intention is to locate tandem call indicators at each of the junction centres and to pass *both* the traffic terminal at the junction centre exchange and that to be *tandemed* to distant exchanges to the tandem call indicator positions.

In order not to delay the tandem call indicator operator on difficult calls and so tend to increase the number of calls waiting at the tandem centre for treatment, it is proposed to arrange for a "helping out" operator to take over from the tandem indicator operator such calls as she is not able to pass forward to objective exchanges on an order wire basis.

It will be seen that the tendency throughout is to eliminate as far as possible the use of an operator with controlling functions. A controlling operator is naturally in a position to take charge of the work of accounting for a call which she controls. If a switching operator is substituted, and

Digitized by Google

her operating time is to be employed in the most economical manner, arrangements must be made for the accounting for the call to be provided for independently of the operator. This would, of course, be done by automatic registration. Various conditions under which automatic registration has to be provided for are shown in the next diagram (Fig. 12).

The *first* is on the full automatic calls, where the answer of the called subscriber prepares the way for the satisfactory registration of the call. The *second* case is that in which the call comes up on a terminal *call indicator junction* associated directly with the automatic exchange junction multiple. In this case, although the manual operator makes the connection at the objective exchange, she does not supervise the call, and the *registration* is dependent upon the answer of the called subscriber. The *third* case is that of a call handled *via* a tandem call indicator position. Here connections are set up both by the tandem operator at the intermediate exchange and the terminal operator at the objective exchange. Neither of these operators has any controlling function, and here again registration has to be provided for on the basis of the answer of the called subscriber.

The *fourth* case is that of a call passed by the originating subscriber to a manual position in the home exchange. This course is necessary if a call involving a *junction fee* is required or if a subscriber is himself unable to obtain a call and requires assistance from the operator. In this case the registration is under the control of the manual operator.

In connection with the first exchange in London it is the intention to utilise order wire junction groups outgoing from junction centres both for the calls originated by subscribers on the junction centre exchanges and for those arriving at the junction centres from the automatic exchange. It is most desirable that any facility enjoyed by the manual exchange "A" operators passing calls over the junctions thus jointly used should not be modified, *e.g.*, control of the front supervisory signal by the answer or by flashing keys on service circuits at the objective exchanges, or by connections to the busy-back at those exchanges. It will consequently be necessary to provide specially wired service circuits, and probably special busy-back jacks also, for use in connection with calls received from automatic exchanges.

MANUAL EXCHANGE SUBSCRIBER
TO
MACHINE SWITCHING EXCHANGE SUBSCRIBER
VIA CORDLESS B BOARD

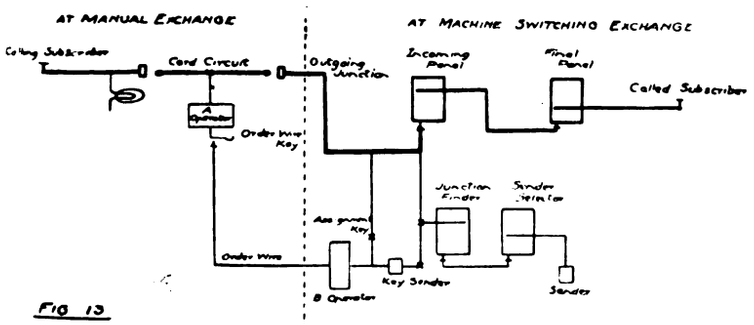

FIG 13

(1) Operation of Assignment Key causes Junction Finder and Sender Selector to operate
(2) Key Sender passes impulses to Sender and is then cut out
(3) Sender causes Selectors on Incoming and Final Panels to operate, after which the Junction Finder and Sender Selector restore to normal

The advantage of enabling subscribers to hear ringing induction when a ring is actually going out to a called subscriber has been demonstrated in practice. It is the intention under automatic development conditions to arrange for this signal to be given to the caller in every possible case. It should ensure reduction in the number of complaints of "Don't answer" and in the verification of such complaints.

We now come to the methods to be followed in passing calls from manual exchanges to automatic exchanges. Three methods are available :—

(*a*) Passage by order wire to "B" positions at the automatic exchange.

(*b*) Dialling direct from the "A" positions at the calling exchange to subscribers on the automatic exchange.

(*c*) The use of what is known as key indicator apparatus.

(*a*) The next illustration (Fig. 13) shows diagrammatically the arrangement employed at an automatic exchange for handling incoming traffic. The "A" operator passes demands to the "B" operator by order wire in the usual way and the "B" operator keys up the required operation. The "B" position (Fig. 14) has no plugs and cords and is generally referred to as a cordless "B" position. It is of desk type with the back portion containing the signals and associated keys inclined at an angle of about 60°. Each position is fitted with a set of keys controlling the selection of the number required by the calling operator. The "B" operator seated at one of these positions has one or more order wires from manual exchanges connected to her headset in the ordinary way. On receipt of a demand for a number she allots a free junction and at the same time depresses the assignment key associated with that

SEMI-MECHANICAL SWITCHBOARD

SECTION OF KEYBOARD
OF CORDLESS INCOMING POSITION

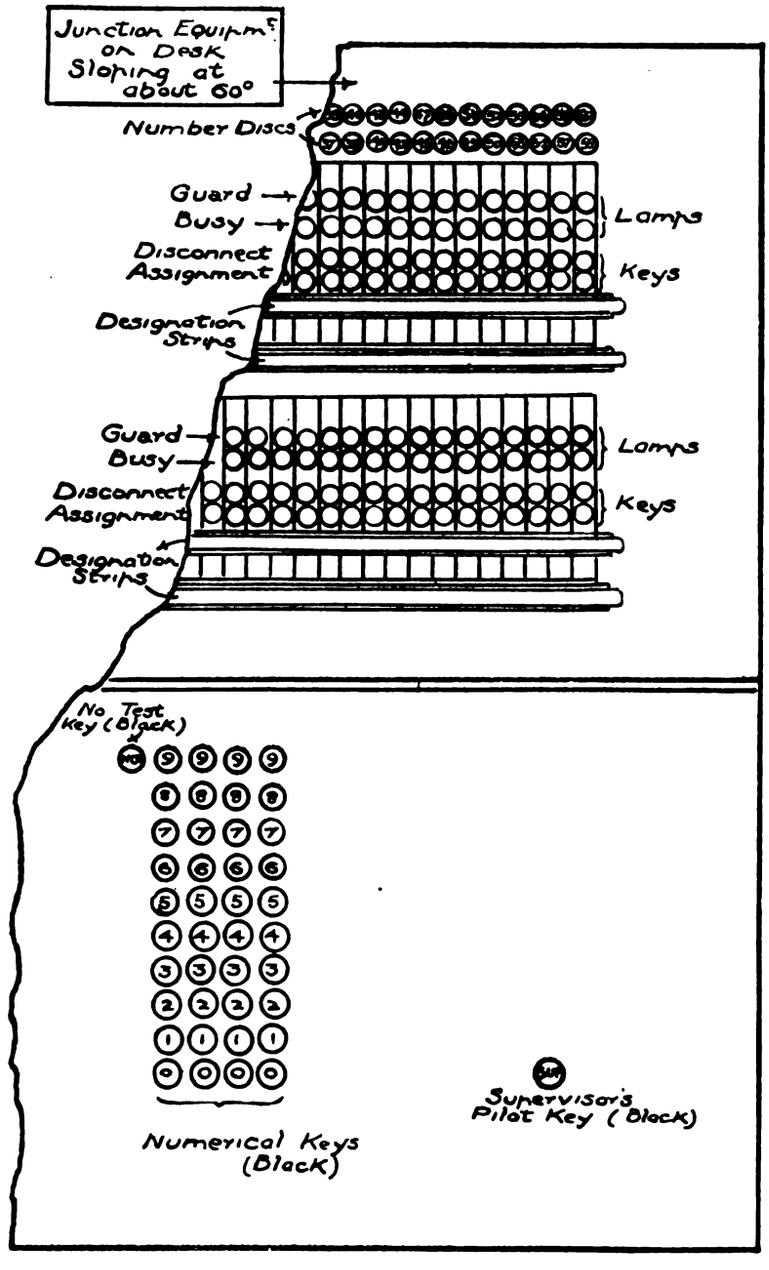

FIG 14

junction, and she proceeds to set up the required number. Simultaneously with the association of her key set with the junction allotted, one of six "senders" is also associated. This is set for impulse sending by the depression of the keys, and takes over the function of transmitting those impulses.

Digitized by Google

The depression of the *units* figure of the key set starts the operation of the sender, and releases the key set for use in connection with another junction and another sender, while the sender first used proceeds to send the necessary impulses over the connecting switches and establish connection with the required number. While the connection is being established the *busy* lamp, which is fitted with a green opal, flashes. When connection has been established the green lamp remains glowing and indicates to the "B" operator that the junction is in use. The answer of the called subscriber controls the supervisory on the originating "A" operator's cord circuit in the usual way. When the "A" operator takes down the connection at the termination of the call, both the "disconnect" and "guard" lamps flash, the "B" operator depresses the disconnect key and the junction becomes available for re-allocation.

The keying can actually race the passage of calls by "A" operators. It is essential, however, that the "A" operators shall not be delayed on the order wires, and the "B" operators load has to be fixed at a point which will not cause reaction on the "A" working.

The "no test" key shown in the diagram is provided on certain "B" positions that will be handling calls from the t ll or trunk exchange. If the "no test" key is depressed before the four numerical keys, the apparatus is permitted to make connection with a subscriber's number even if that number is engaged. The key is used on certain calls which necessitate a connection to a subscriber's line on the "B" side while the line is being held elsewhere. It is also used in connection with complaints from subscribers of having been cut off etc

KEY INDICATOR EQUIPMENT

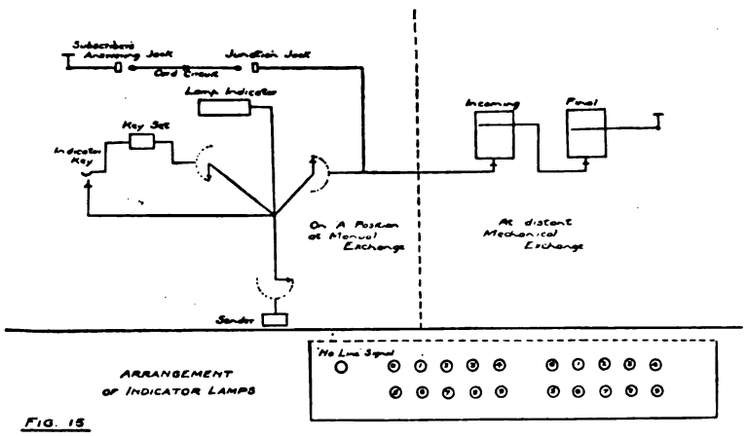

FIG. 15.

(*b*) Direct calling from "A" operators can be secured in one way by the provision of dials at "A" positions. This involves (1) the modification of the cord circuits in order to provide for the association of the dial with each cord as required (or alternatively the provision of a dialling jack in connection with each junction) and also (2) the selection of junctions on a manual testing basis before the dialling operation can commence. The present intention is to instal dial calling in London to Blackfriars Exchange, the first automatic exchange, from all exchanges which, under manual conditions, would have been provided with direct signalling junctions to the objective exchange.

(*c*) The standard method of the Western Electric Company, in the case of any manual exchange which will remain in service for some years during the transition period, is to provide what is known as "key indicator" equipment on the "A" positions. Under the key indicator method each "A" operator is provided with a set of sender keys, located at the right-hand side of her position. No modification of the cord circuits is necessary for the purpose of associating this key set with the junctions to automatic exchanges. Fig. 15 shows the arrangements in skeleton form. Access to the junctions is obtained in the first instance by the depression of the key in the order wire field. The key is labelled with the code of the distant automatic exchange and on its depression the following operations take place :—

(*a*) A junction to the objective exchange is automatically selected.

(*b*) One "sender" of a group allotted for the general use of a suite of "A" positions is associated with the junction.

(*c*) The key set of the position on which the coded key is depressed is associated with the selected sender.

(*d*) The number of the junction selected is displayed on an indicator in front of the "A" operator. This indictor consists of two strips of lamps mounted in the answering jack field below the multiple. They have digits engraved on the opals as follows :—

0 1 2 3 4	0 1 2 3 4
5 6 7 8 9	5 6 7 8 9

Mounted at the left of the top row of lamps is a lamp known as a "no line" signal.

Immediatelv after depressing the junction selecting key the "A" operator sets up the required number on the key sender and then plugs into the assigned junction. The act of plugging into a junction disconnects the operator's position from the sending apparatus and darkens the junction indicator. If no junction is available for the call the "no line" lamp glows. In this case the operator may wait until a line is found and the indicator is displayed, or she may try the call again later.

In any automatic system difficulties may occur from several causes. A subscriber may make a mistake in his dialling or he may not complete the dialling for the whole of the call. In the ordinary course any errors of this sort made on an exchange of the direct impulse type would take his call to a certain point in the train of switches and would leave it there. This point may be somewhere beyond the originating exchange. Under the *Western Electric* switching conditions provision is made for every case which has failed to complete the full sequence of operations to be brought to notice *at the originating exchange*, even although the failure has taken place at some external point. If a call fails and a subscriber does not *hang up* within a period of time which can be previously determined, he is transferred to a special operator who is known as the "sender" operator, and is located in the apparatus room of the originating exchange in close touch with the maintenance staff.

Circuits upon which such calls are connected provide for the following indications to the sender operator :—

Steady bright light ...	when subscriber has lifted his receiver, but has not dialled.
Dim light	when subscriber has partially dialled.
Flashing light ...	when dialling has been completed but the mechanism has not completed the call.

The connections to the sender operator are made without modifying the actual connection set up *via* the automatic switches. In the case of a call which is delayed in transit, the sender operator does not know from her lamp indications where the delay has taken place, but she refers the whole matter at once to the maintenance staff at the home exchange while the connection is being held.

The facility of referring these calls with which difficulty has been experienced to a special operator in this way undoubtedly tends to ensure the smooth running of the service and provides a subscriber with assistance at the time when he most requires it. This feature may prove to be of considerable use especially in the earlier stages of automatics in London, during which subscribers will be called upon to interpose ciphers between the exchange code and number where the required subscriber's number consists of less than four digits. There is every probability that a number of cases will occur on which the subscriber *fails* to dial the necessary ciphers and the call will consequently be stranded on the exchange as an uncompleted call.

Throughout the development of the Western Electric system the fact that the exchange apparatus is not in a position to receive a subscriber's dial impulses *immediately* he lifts his receiver has necessitated the use of what is known as a "dialling tone." On the lifting of the receiver certain switching operations have to take place at the exchange and these have to be completed before the subscriber commences to send the first digit of his required number. If he dials before the circuit conditions have been prepared his call will fail. The dialling tone thus takes the place of the manual operator's salutation, "number please."

Types of manual positions to be provided.

The positions required for the handling of calls incoming to the new exchange have already been described. It will be necessary to provide also for the handling manually of certain calls originated by the automatic subscribers. The calls passed to a manual board will be of the following types :—

(*a*) Those on which a subscriber requires an exchange outside the local fee area ; therefore involving the preparation of a charge ticket.

(*b*) Calls on which the subscriber has had difficulty, or is in doubt, and requires the assistance of a manual operator.

(*c*) Calls for the purpose of making a complaint.

(*d*) Requests for information.

(*e*) Calls for trunks, toll or telegrams from subscribers not entitled to those facilities.

For the *fee junction* and *operating assistance* calls subscribers will dial "O" For complaint and information work separate codes will be allotted to subscribers, which they will dial and bring up signals on manual positions, the labelling of the lines at these positions intimating to the officer handling the call the general nature of the requirements.

There will be codes for obtaining either trunk or toll telegram facilities, and subscribers who are entitled to full facilities will, on dialling the respective code, be connected direct to the point at which the service can be given. Subscribers who are not authorised to make calls for trunks, toll or telegrams will be connected on special panels of the exchange. If either of these subscribers

Digitized by Google

makes a call for one of those services the connection will be diverted to a special group of lines terminating on the manual positions.

In addition to the handling of the traffic of the types mentioned. operators at the manual positions will have to be in a position to handle the ordinary work of information desks, including changed number work, guard signals, and the verification of cut-offs," "engaged" and "no reply" reports.

The manual positions supplied will be provided with double-ended cords with the usual two supervisory signals and speaking, ringing, register, dialling and flashing keys. Order wire keys will be provided on each position, mainly for the purpose of affording the manual operators direct access to the junction centres through which in many cases connections to exchanges outside the local area will be obtained.

In the standard Western Electric design provision is made for very complete records of traffic at various points throughout the exchange. Each group of switches and junctions is provided with a peg count register which operates every time a call is set up, and with an overflow register which operates when, with the whole group engaged, an additional call is received which cannot be connected. Each separate group of junctions on a cordless "B" position is equipped with an electrically-operated peg count register, which operates each time one of the assignment keys in the junction group is depressed.

In a typical American Exchange, designed to provide service to about 6,000 subscribers, with a busy hour calling rate of 2.16 and 50 per cent. junction traffic, the number of peg count and overflow registers provided would be as follows :—

PEG COUNT REGISTERS.

For.	No. of Registers.
Special "A" positions	12
Junction groups at cordless "B" board	8
Line finders	89
Incoming junctions	42
Office selectors	3
Final selectors	56

OVERFLOW REGISTERS.

Line finders	22
Senders	8
Junctions on the district panel multiple	14
Junctions on the office panel multiple	15
Junctions on the incoming multiple	56

The provision of traffic registers on a very complete basis is simplified under a system which makes each group of circuits individual and distinct and not subject to the interconnecting which is so frequently practiced in connection with plants of the Strowger type. It is common knowledge that as a group of lines increases, the number of calls which each circuit in the group can carry also increases. The increased carrying capacity is. however, not proportional to the increase in the number of lines. The rate of increase in carrying capacity is large in the case of small groups, but comparatively small as the groups become larger. The panel system provides generally for the utilisation of groups which exceed in size those which are affected by a rapid increase in the carrying capacity, whereas the 10 terminal limitation experienced with plant of the Strowger type provides a much wider field for the utilisation of any device which offers some advantage from the increased line capacity point of view. There may be some cases in the panel system which justify a use of overlapping sections of a junction group, but it would be obvious that the study of traffic fluctuations in the system would be much more complex under such conditions and it is *doubtful* whether the effect that such a course would have on the provision of registers and the use of register readings would be justified.

METROPOLITAN TANDEM EXCHANGE

ARRANGEMENT OF KEYS AND ROUTING CHART

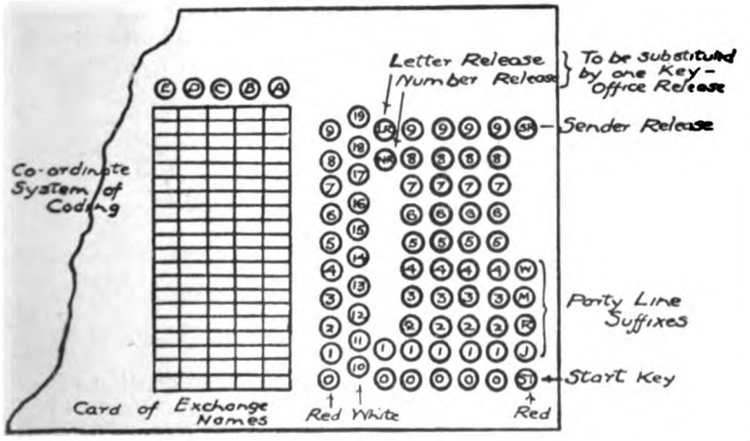

FIG. 16

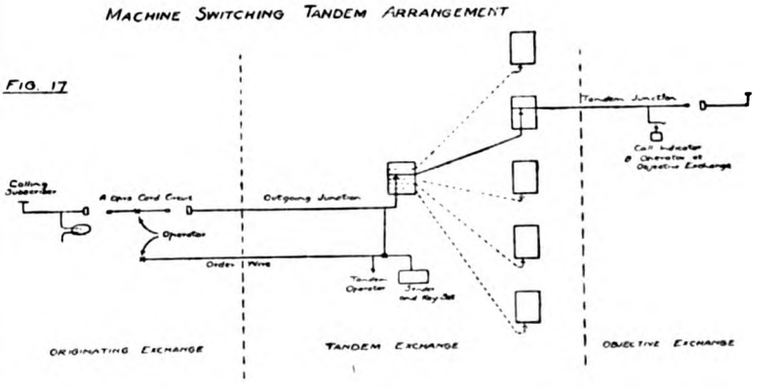

An interesting possibility arising out of the flexibility in junction routing with panel apparatus and translators is the utilisation of machine switching equipment for working through what is known as a "tandem" exchange. Under existing conditions in London a large number of small junction groups are in use—many of them working on the signalling basis, which involves a distinct drag on the time of the "A" operators. With a machine switching tandem exchange large groups, working on an order wire basis, can be established between each local exchange and the tandem exchange. In the case of a call to an exchange with which an "A" operator has no direct communication, she passes the exchange name and number of the objective subscriber on the tandem order wire. The tandem operator is provided with a key set which enables her to select automatically a junction to the objective exchange and to *pass on* the subscriber's number automatically to a call indicator operator at that exchange.

The diagram (Fig. 16) shows the arrangements of the key shelf at the tandem exchange. The names of the exchanges reached *via* the tandem operator appear on the card shown adjoining the keys. It will be seen that each name is associated vertically with a lettered key and horizontally with a numbered key. The operator has junction keys similar to those on a cordless "B" position. She allots a junction for each demand passed to her, and immediately presses, first the lettered and numbered keys co-ordinate to the name of the required exchange—thus selecting automatically a free junction to that exchange—then, the numerical keys corresponding to the called subscriber's number—and finally the start key.

Fig. 17 shows in a skeleton manner the inter-relationship between the calling and called exchanges. The order wire to the tandem centre, the position of the key set, the selection of the junction group required and the path taken to the call indicator at the objective exchange are all shown.

MACHINE SWITCHING TANDEM ARRANGEMENT

FIG. 17

The same panels and junctions can be used eventually for full mechanical calls in order to economise in the establishment of direct junction routes ; and during the transition period an exchange of this type should be of immense value to local manual exchanges. The details of an exchange of this type for London are now being worked out. A mechanical tandem exchange was brought into use in New York on April 17 last.

In conclusion, I would emphasise the fact that many matters must have special study if the development of automatic conditions is to be satisfactorily carried out in London. They include :—

The psychology of the subscriber.

The psychology of the operating and supervising staff.

The *adequate* education of engineering and traffic staffs.

An expert and well-informed publicity campaign.

The parallel development of plant, traffic design and service aspects of the new system, with the closest possible co-operation of distinct and clearly defined functions.

And may I urge that adequate provision be made by the Administration for the proper study of these matters, as the every-day work of well trained men who, so far as the detailed study officers are concerned, are free from the distraction of executive duties.

THE BAUDOT.—XVII.

By J. J. T.

FIGS. XLIX and L are diagrams of the impression or printing wheel V^1, the teeth of which are engaged by the cam Ca (Figs. XLVIII and LI). The details of this wheel and its appendages will be dealt with in another chapter. In the meantime, having taken a general view of the mechanical action which results in the engagement of Ca with V^1, action which finally results in the printing of any letter or sign signalled, it will be time and space well occupied if we study a little more closely the details of that portion of the mechnical movement which we examined last month. Figs. LI and LII, especially the former, will help us to do this. Fig. LII shows the retaining end of the click *C*, together with an upper spring Q, not shown in Fig. XLVIII, which spring firmly engages C with Ca until released by the action of the hammer-head H. Fig. LI gives the positions in which the propelling rod finds itself in the cycle of movement consequent on the printing of each letter.

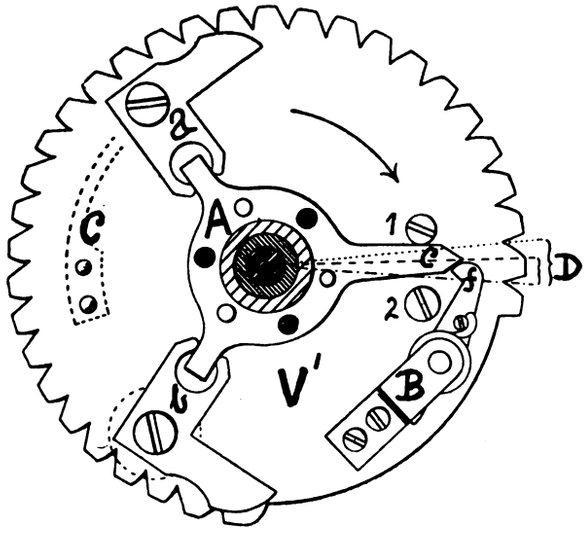

FIG. XLIX.

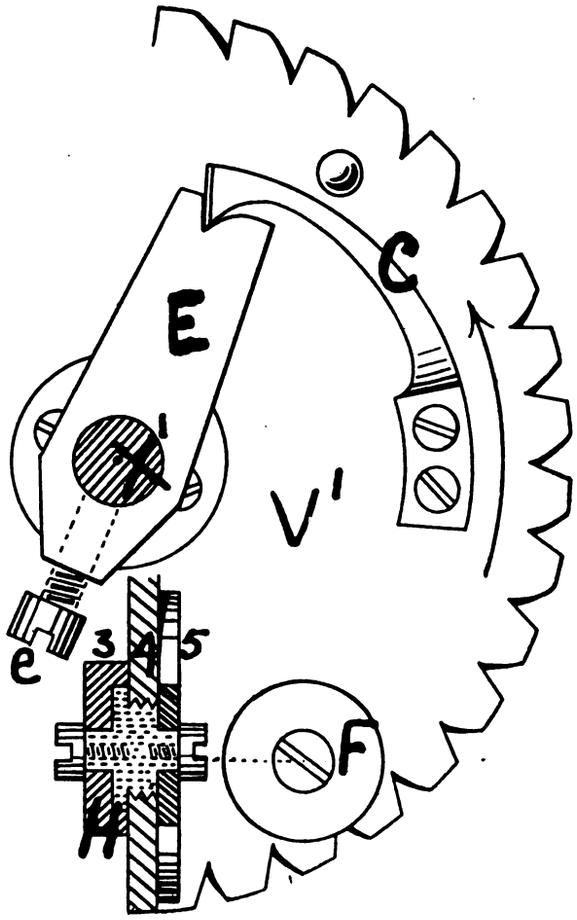

FIG. L.

We know that when any combination of signals is received the selector levers take up certain positions over the *rest* and

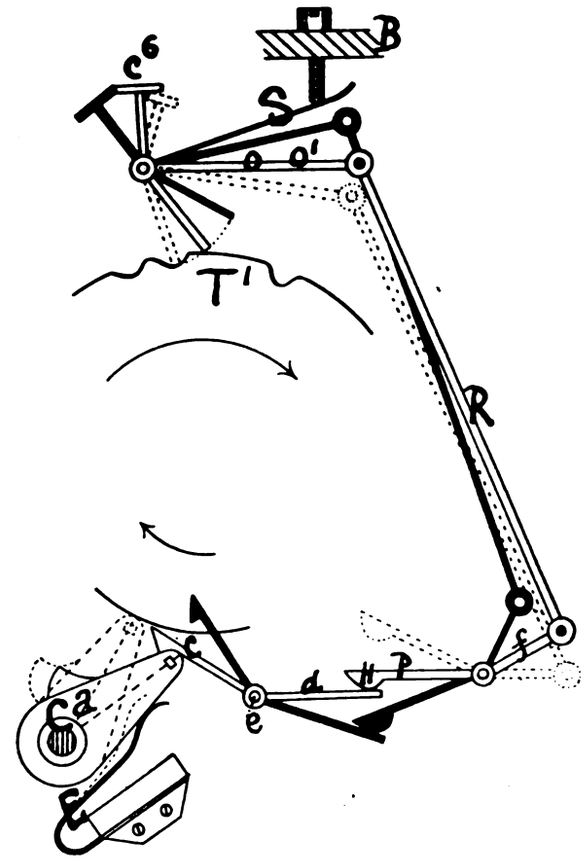

FIG. LI.

working tracks of the discs T and T^1 (Figs. XLIV, &c.), and that the pressure of the spring S (Figs. XLVIII and LI) acting upon the propulsion lever OO^1 and its appendage C^6 conveys that pressure to the selector levers C^1 to C^5, as all six (C^1 to C_5 plus C^6) from part of the same arc. This pressure is exerted in the direction from left to right, *i.e.*, viewing the Baudot receiver from the front.

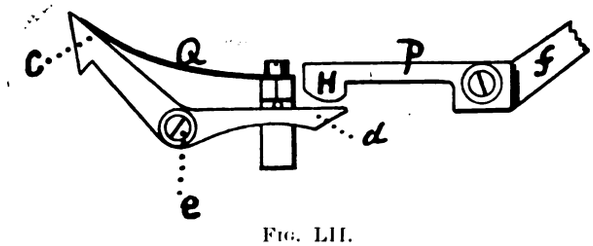

FIG. LII.

When the combiner wheel brings round the combination of slots and blanks which correspond with the letter to be printed, the pressure of the spring S acting upon C^6 forces he selector levers into their selected slots. This first impulse results in a slight movement of the pedal P as represented by the dotted lines (Fig. LI). The speed of rotation of the combiner wheel, however, immediately

Digitized by Google

throws the selector levers out of these slots, causing a rebounding action, which has the effect of changing the position of R in the reverse direction and of placing C^6, R, P, and the retaining click C in the positions shown by the blackened lines of our diagram. It will, therefore, also be noted that it is in this position that the release of the printing or impression cam Ca is effected, permitting the latter to engage with the teeth of V^1 underneath which it is located. The third, outlined and lettered positions of the propulsion lever, rod and pedal are of course the positions of these parts when no printing is taking place.

(To be continued.)

REVIEW.

"Telegraphy, Telephony, and Wireless." By J. Poole, A.M.I.E.E. Sir Isaac Pitman & Sons, 3s. net.—This little book is an admirable example of intelligent compression. In the compass of little more than a hundred pages, Mr. Poole contrives to give a clear outline of the technicalities of telegraphy, telephony, and wireless telegraphy and telephony. The explanations are especially suitable as a foundation for further study. In respect of wireless we are given a good account of the history of its development, bringing it down to the latest inventions, including the thermionic valve. It is not a technical text-book, but it is more than a hand-book for the general reader, in that it gives a sufficiently clear outline for the many of us in the service who need to know something of the technical side of the subject for our day-by-day work. It would be an obstinate reader who would master this book and not gain from it a desire for a fuller knowledge. We should say ourselves that in respect of radio-telephony, Mr. Poole is a little on the optimistic side. "Not only," he says, "is wireless telephony feasible under such circumstances, but it is much better in quality than any wire telephony could be if transmitted a long distance by cable, if that were practicable." To us that seems to be a little extreme, but of course there is no evidence to the contrary. However, we are not criticising the book on this ground. On the other hand, we welcome it as being particularly useful to the service at this moment.

LONDON TELEPHONE SERVICE NOTES.

Miss Ralph's Retirement.—A familiar figure in the telephone world passed out of it when Miss Ralph retired on Dec. 31. She had been connected with telephones since 1882, when she entered the service of the United Telephone Company. When that Company was absorbed by the National Telephone Company, Miss Ralph continued in the service of the latter, and in 1884 became the Clerk-in-Charge of Deptford.

In 1889 the first telephone training school was opened at London Wall, and Miss Ralph was appointed the school-mistress with two assistant teachers. It is quite true to say that she was the first telephone school-mistress, in the world. At the transfer of the National Telephone Company to the State, Miss Ralph retained her position as head of the London Wall School and remained there until a year ago. During her last year of service, Miss Ralph has supervised the three training schools and given special attention to the post training of learners in exchanges.

It was felt by those who had been associated with her for such a long period that some practical expression should be made of the esteem and respect in which she is held, and a very pleasant little ceremony took place on Jan. 13 in the great hall of the Sunday School Union, Old Bailey, E.C. Speeches were made by Mr. Stirling and Mr. Edmonds, Assistant Controllers, by Miss Newman, Supervisor of the Avenue Exchange, and by Miss Turner, Telephonist, all expressing the regard which Miss Ralph has won for herself in her long years of service. Mr. Preston, the Controller, in a very happy speech, recounted some of the incidents in Miss Ralph's career, and ended by presenting her with a War Loan Certificate for £178 10s., the gift of her many friends, both in the Service and out of it. Miss Ralph takes with her the good wishes of all who knew her in the Telephone Service for good health in which to enjoy her retirement.

To those who were unable to be present at the presentation, Miss Ralph sends the following message :—

Friends and Comrades.—On an occasion such as this, it is most difficult to find words adequately to express my appreciation of the great honour conferred on me this evening. That it is an honour, I am well aware, but I have but done my duty, and that could not have been carried out were it not for the help of a loyal staff—you all have helped—therefore the honour reflects on you and should be shared. In March next I should have been 39 years in the Telephone Servcie, having commenced with the United Telephone Co. in 1882. They have been happy years—in spite of difficulties—especially this last year when I have been able to visit all the London Exchanges and meet old friends whom I had not seen for some years, as well as seeing many who left me from the school little more than school girls and who are now taking responsible positions.

I began by stating how difficult it was to express oneself adequately. Will you look up yourselves the choicest words you can find and would have me to say—take and frame them together and accept them as the expression of my warmest heartfelt appreciation and thanks for your generous gift and the honour which you have conferred on me. May I take this opportunity to thank all who have written such kindly expressions of good will and comradeship, but to whom it would be impossible to write individually.

The London Telephonists' Society celebrated the opening of 1921 by a New Year's Dance, held at the Bishopsgate Institute on Saturday, Jan. 1. There was a keen demand for the tickets, every one of which was sold, and the room was filled without being packed. The Dance Committee were congratulated on all hands for the excellence of the arrangements; the refreshments, always a matter of consideration, being appetising in quality and abundant in quantity. The M.C.s, Mr. Guy Buckeridge and Mr. Beck, with their stewards, were assiduous in securing the comfort and convenience of all, whilst Mr. Skinner's orchestra, as ever, provided music that for anyone who might, could, would or should, at any time dance or contemplate dancing, was simply irresistible. One thing there was that marred the complete happiness of the gathering, and that was the entire absence of the "chiefs"—yet the heart cannot always be worn on the sleeve, and so those present hid their griefs, and it is doubtful if the visitor from without the magic circle of the L.T.S. ever realised the aching void left by these absences.

Miss Heap read her paper, recounting her holiday in Italy, before a large audience in the great hall of the Sunday School Union on Jan. 13. The enthusiasm of Miss Heap's explanations and descriptions of the pictures thrown on the screen told of the enjoyment of such a holiday. Miss Heap undoubtedly expressed the wish of her hearers when she hoped that they would have an opportunity of making the journey personally at some future date. It is unlikely, however, that such good fortune will come to many of the audience, and the rest are glad to have heard of Italy's charms on this occasion.

The next meeting takes place on Feb. 2, when the competition papers will be read.

The Langham Choral Society.—The next work to be presented is Mendelssohn's "Elijah." The performance will take place at the Queen's Hall at 7 p.m. on Friday, Feb. 18, and the previous successes are leading to a large demand for tickets. The following eminent vocalists have been engaged :—Mme. Elsa Stralia, Miss Lucy Nuttall, Mr. Ivor Walters and Mr. Robert Radford. Enquiries concerning tickets, &c., should be addressed to :—Miss W. M. Nurse, West District Traffic Office, L.T.S., 11 12, Norwich Street, E.C.4.

Headquarters.—The Cenotaph continues to be well supplied with wreaths and floral tributes. Prior to the Christmas festival the staff of the Controller Office purchased a fitting wreath, which was taken to the Cenotaph by representative ex-Service men and women as a tribute to those no longer with us.

Sympathy with the ex-Service men unemployed at the festive season was expressed in a practical manner by means of a collection at Headquarters, which secured £26 for the unemployment fund of the Discharged Soldiers' and Sailors' Federation.

The Trunk Exchange.—Caxton Hall, which has associations over long years with the movement for the advancement of women, was thronged on Monday, Jan. 10, by a host of enthusiasts of the gentler sex. Their enthusiasm was engendered by the anticipations of a social and dance, but it was fanned to a flame of white heat by their desire to do honour to one woman. That one was Miss Beaumont, and those enthusiasts were members of the Trunk Exchange staff, congregated to express to her, without the trammels of standard expressions or official parlance of any kind, their unbounded regard for her, their appreciation of all she had done for them, and their high hopes for her future happiness and advancement. All this they expressed at an interval in the proceedings when Mr. Kennedy on their behalf handed to Miss Beaumont as an outward and visible sign of their feelings a ring set with a large ruby in a cluster of diamonds. Hardly had the sound of Mr. Kennedy's voice ceased when Miss Chaplin, on behalf of the local representatives of the U.P.W., presented Miss Beaumont with a solid silver vase, this being followed again by Miss Temme, who gave a fountain pen as a memento from the Swimming Club, whereafter Miss James placed in Miss Beaumont's hands a bouquet of orchids, pink malmaisons and lilies of the valley. Is it any wonder that Miss Beaumont's voice trembled just a little as she acknowledged these gifts? Is it any wonder that the whole of those present burst into cheers, finally joining vigorously in an adaptation of that ancient melody of praise "For she's a jolly good fellow?" If it is a wonder to you, reader,

Digitized by Google

it is clear you know nothing of Miss Beaumont, and less of the Trunk Exchange. It was a fine tribute, well paid and richly deserved. The musical programme was of a high quality and the dances were things of life as dances should be. Of course the gathering had to break up, but then life is just like that, which is one reason why the Railway Companies always print the times of the last trains in heavy type.

Telephone and Telegraph Society.

A very interesting paper on the subject of "Wireless Communications" was read by Lt.-Col. C. G. G. Crawley, R.M.A., Deputy-Inspector of Wireless, at the January meeting of this Society. There was a large audience, but few members from the telephone side were present. We were glad to welcome Sir Andrew Ogilvie, who, in his remarks, expressed the purpose of many present—namely, to hear something of the work and progress of our colleagues in other branches of the Post Office. It will be news to many to learn that the staffs at the P.O. wireless stations have definite responsibilities in connexion with the safety of lives at sea. Although wireless telegraphy may be regarded as dating, from a commercial point of view, from 1896 or 1897, it is still, judging from some of the sallies which passed, far from that degree of efficiency towards which it is common knowledge that Officers of the P.O. aim. Col. Crawley was optimistic concerning the future of wireless telephony, which, having its birth during the war, is still a very small infant, yet it promises to rival its wireless brother (or is it sister) in certain respects. He explained that it is quicker than telegraphy, seeing that it requires no transscription of signals, and consequently it has the advantage of not requiring a skilled signaller. On the other hand, it cannot yet be made so secretive, nor has it so long a range for a given power. It is interesting to learn that communication by wireless telephony is in force between a point in California and a neighbouring island, a distance of about 30 miles.

From what we heard we may conclude that before many weeks are passed there will be a regular wireless telegraph service between this country and Germany, outwards from Stonehaven to Berlin, and inwards from Berlin to the Central Telegraph Office.

At the meeting to be held on Feb. 21, Mr. T. C. Cook, of the Accountant-General's Dept., will read a paper entitled "Studies in Whitleyism."

Telephone Repeater Demonstration.

Readers of the JOURNAL have no doubt seen the notes published from time to time regarding the progress made with telephone repeaters. These repeaters depend upon the principle of the "thermionic valve" and the use of "valves" will inevitably play as important a part in the development of wire telephony as it has in the development of "wireless"—both telegraphy and telephony. We watch with interest the progress of the various underground cable schemes, and hear of the completion of new "repeater" stations here and there for telephone purposes, as these are signs that we are keeping pace with the developments at which other progressive countries are also aiming—developments which may assist in forging the bonds of international understanding and unity.

But few of us have been fortunate enough so far to see these wonderful repeaters in operation. There is, therefore, great interest for every telephone enthusiast in the demonstration circuits and apparatus established by the Western Electric Company, at 62, Finsbury Pavement, and all who are able should arrange, by appointment with the Company, to see the repeaters in operation and hear from an expert the many wonders to be told of them.

Two circuits are installed, one a two-wire circuit with one repeater station, the other a four-wire circuit with two repeater stations. The latter circuit is of particular interest, as it involves such a complete departure from our previous conception of what a telephone circuit should be. The two circuits can be connected together to produce a circuit of which the standard cable equivalent is well over 100 miles. Without repeaters it is of course quite impracticable to speak over such a circuit, but with the repeaters in circuit the speech equivalent is brought down to a point well below 20 miles of standard cable.

We hope and expect the time is not far distant when repeaters will be established not only throughout the British Isles but also on main continental routes, which will bring Rome, Copenhagen, &c., into as easy reach of London telephonically as Manchester and Liverpool are to-day.

The "Telephone Ramp."

Newspapers placards announce "A Telephone Ramp."
Oh, startling confession!
Unheard of remorse!
Which each of our readers
Will gladly endorse.
The press, with a candour
Where truth sets its stamp,
Admit, they're conducting
A Telephone Ramp!
Ingenuous placards.
We know it too well,
(Though why you confess it
It's harder to tell).
Whether tardy regret,
Or a traitor in camp—
The *press are* conducting
A Telephone Ramp!

An Open Letter to :—

THE EDITOR,
Daily Telegraph.

You gave a wrong number, Mr. Editor, to millions of subscribers on New Year's day. In accordance with your index they were connected to page 10 for that most vital of all communications "Telephone Charges" only to find that the number was a wrong one. They heard no sympathetic "Sorry you have been troubled," and after searching through sixteen pages (it used to be many more), for which you have increased the charge 100% in spite of protests, the correct number was found to be 7. Apparently you had not turned over enough "new leaves." The error is not an isolated one. It was repeated on the 17th idem, when your contribution to the same subject appeared on page 9 instead of on page 12 as announced in the index. The British press is the most inefficient in the world! Why do you not learn from your American contemporaries how to run a newspaper efficiently?

Yours &c.

* * *

Regent Exchange.—On Saturday, Jan. 15, Regent entertained their protégés at Gifford House, Rochampton, to a special New Year's tea and concert. In addition to the truly royal spread provided at tea-time, each guest was presented with a useful gift. The concert which followed included interesting and talented items, which were so much appreciated by the men that they declared they "were not a bit sorry they had missed seeing Chelsea play" What greater tribute can a man give?

PERSONALIA.

LONDON TELEPHONE SERVICE.

Mr. J. A. RENWICK, Clerical Officer, attached to the Accounts Branch of the Controller's Office, has been promoted Second Class Clerk, Investigation Branch, Secretary's Office.

The following officers have resigned on account of marriage:—

Miss L. WHEATLEY, Asst. Supervisor Class II, of Paddington Exchange.
Miss A. L. BARRATT, Telephonist, of Avenue Exchange.
Miss A. A. BROWN, Telephonist, of East Exchange.
Miss M. MCMURCHY, Telephonist, of East Exchange.
Miss C. BUNCE, Telephonist, of Holborn Exchange.
Miss M. E. LOFTS, Telephonist, of Holborn Exchange.
Miss A. SOLLY, Telephonist, of Hornsey Exchange.
Miss E. BOTTOMS, Telephonist, of Museum Exchange.
Miss D. E. GREEN, Telephonist, of Trunk Exchange.
Miss B. M. SHONE, Telephonist, of Victoria Exchange.
Miss L. M. SMITH, Telephonist, of Victoria Exchange.
Miss D. F. GARDNER, Telephonist, Victoria Exchange.
Miss E. A. BANKS-FAY, Telephonist, of Victoria Exchange.

OBITUARY.

MR. ROBERT MCLEAN.

We greatly regret to record that Mr. Robert McLean, for 20 years Manager and Engineer of the Guernsey States Telephone Department, died suddenly, Dec. 30, 1920, at his residence, Hermes, Castel, Guernsey; Mr. McLean, who was exceedingly well known in Telephone circles, was born in 1869 at Musselburgh; apprenticed to the National Telephone Company, Edinburgh, 1885; Chief Inspector, Mutual Telephone Company, Manchester, 1890; Chief Inspector, New Telephone Company, London, 1892; Local Manager with National Telephone Company at Cardiff and elsewhere, 1894; appointed to Guernsey, 1900. Under his care the Guernsey Telephone System increased from 679 stations in 1900 to 2,700 at the end of 1920, and obtained a great reputation for good and economical service and administration. Mr. McLean, who leaves a widow and a wide circle of friends, was accorded a semi-public funeral at Castel Church, in recognition of his long and faithful service.

BIRMINGHAM.

The first annual dinner of the Telephone Cricket Club took place at the White Horse Hotel on Dec. 2. A capital dinner was served and an excellent musical programme rendered. The Toast list was as follows:—

The King, proposed by the Chairman.

The Telephone Cricket Club, proposed by Mr. C. W. Piggott and responded to by Mr. G. F. Findley (captain).

The Post Office Sports Club, proposed by Mr. Wiggins and responded to by Mr. H. Blackmore and Mr. R. Smith (secretary and assistant secretary respectively).

The Artists, proposed by Mr. Rhodes and acknowledged by Mr. Thomas.

The toast of the chairman was in the hands of Mr. Llewellyn.

A résumé of the Club's achievements during 1920 was presented by Mr. Price (secretary). Mr. H. Bristow presided, and the proceedings throughout were acclaimed by all to have been an unqualified success.

Printed by A. P. BLUNDELL, TAYLOR & CO., 171-173, Upper Thames Street, London, E.C.4, and published by the EDITING COMMITTEE (JOHN LEE, J. J. TYRRELL, W. A. VALENTINE and J. W. WISSENDEN, General Post Office North, London, E.C.1.

THE POST OFFICE AND THE TELEPHONES.

BY A P.O. OFFICIAL.

[Leading article in Sir Isaac Pitman & Son's monthly magazine *Business Organisation*. Reproduced by permission.]

THE remarkable press campaign which has followed the announcement that the Postmaster-General has adopted the revised scale of telephone charges recently agreed to by a Select Committee of the House of Commons is in striking contrast to the equanimity with which the report of the Department Committee, which framed these charges, was received on its publication in June of last year. Most newspapers then published a full announcement of the new rates proposed but the comments made were rather of an explanatory than an antagonistic nature. It is no secret that the administrators of the Post Office anticipated a good deal of public opposition to the proposals on their first announcement and are surprised that the storm has only burst, in unexampled fury, *after* these proposals have received the approval of a Parliamentary Committee appointed for the very purpose of assuring the public that the increased charges had not been arbitrarily imposed but had been carefully and reasonably framed to meet the financial needs of the situation.

THE ATTITUDE OF THE PRESS.

One cannot but sympathise with the harassed citizen who, after finding his expenses of all kinds soaring to the skies, looks upon the long deferred increase in the cost of his telephone as "the last straw." With the manner in which the subject has been treated by the Press one has less sympathy. It has been unreal, and it has been strongly swayed by ulterior motives. Plentiful space has been provided for the wildest exaggeration and the most obvious misrepresentation on the one side, while the few statements that have been made in defence of the Post Office have been very generally garbled or refused publication. It is easy to see that the supposed deficiencies of a Government Department, engaged in conducting a great national business, have been seized upon as a weapon by means of which the whole principle of the nationalisation of industry may be resisted. It is quite possible, however, to hold that support of a nationalised telephone system does not commit one to any general support of nationalisation as a theory. The telephone system naturally links itself with the other systems concerned in the transmission of intelligence—the telegraph system and the postal system. All three services have, in common, the feature that they must from their very nature be under a general co-ordinated control in order to reach maximum efficiency. They are natural, nation-wide, monopolies and, as such, they have a particular claim to be looked upon and conducted as a national property.

Discussion of the telephone charges has to a great extent centred itself around the question of the efficiency, or inefficiency, with which the Post Office is carrying on the business, but let us leave this important question aside for a moment, for the very cogent reason that even if it were proved that the telephone system requires complete re-organisation and can only be made efficient by handing it over to a commercial company it is manifestly impossible that such a company could carry out such a re-organisation and make it effective, at once. For the next few years, therefore, the service must either be carried on by means of a national subsidy or the necessary additional revenue must be raised by increasing the charges paid by its subscribers.

THE CASE FOR AN INCREASE IN RATES.

The policy of the Government is that the telephone system should be self-supporting; it should not be looked upon as a regular source of profit, contributing to the public revenue, neither should it be a financial burden upon the general tax-payer. Up to the time of the War it fulfilled these conditions. After meeting all charges, direct and indirect, and paying the standard rate of interest on the capital sunk in the undertaking, it contributed to the Exchequer a small annual balance, in the nature of a margin of safety. Revenue and expenditure were practically in equilibrium. It is obvious that this equilibrium has been rudely upset by the great increase in costs of all kinds that has followed the War, and it should be common ground that a substantial increase in the payment made for the service is necessary to restore the balance. Corresponding increases are being, or have been, made by telephone

Digitized by Google

administrations all over the world. In many cases the proportion of increase is much higher than has been found necessary in this country. In some other countries, such as America, where for various reasons the effective purchasing power of money has not depreciated to the same extent as in Great Britain, a smaller *proportionate* increase has sufficed.

METHOD OF REVISION.

The Postmaster-General, in agreement with the Government, deliberately abstained from proposing that an increase in telephone rates should closely follow the termination of hostilities. It was felt that those engaged in the reconstruction of business of all kinds had great financial difficulties to face and that, in the exceptional circumstances, the Exchequer might properly be called upon to bear some temporary loss in connexion with the public telephone service. The revision now announced has been the subject of investigation in great detail by a Departmental Committee of accounting, engineering, and commercial telephone experts, and, as already mentioned, the conclusions of this committee were concurred in, after careful consideration, by a Select Committee of the House of Commons, representing all political parties, and with full powers to call evidence from all quarters. On no previous occasion have proposals in connexion with telephone charges been submitted to the House of Commons or to any outside authority. The National Telephone Company and the other private companies in whose hands the telephone business of this country has at various times been placed, altered the rates at their pleasure. In many matters of much greater financial moment the public has to submit to the dictation of purely private interests. We are only too well accustomed to the idea that a few individuals may meet together in secret and settle, largely from the standpoint of their own personal profit, what the public shall pay for its wheat or its beef, or what industry shall pay for its steel or its copper, or cotton, or oil. Such operations are quietly approved in many quarters from which much bitter outcry on the subject of telephone rates is now proceeding. In view of the exceptional care which has, on this occasion, been taken to safeguard the telephone-using public from any arbitrary or irresponsible action, much of this outcry can only be classed as artificial or void of perspective.

AMOUNT OF AVERAGE INCREASE.

The new rates would bring in a revenue about 67 per cent. higher than that produced, *for the same amount of service*, by the existing rates, which already include an increase of about 8 per cent. made during the War. Compared with the strictly pre-war rates the total increase is therefore about 80 per cent. The Post Office anticipates that this increase will lead to a reduction of traffic, without appreciable inconvenience to subscribers, which will probably reduce the theoretical revenue to an actual figure about 57 per cent. in excess of the revenue at the old rates. These figures represent the *average* increases in the charges made to subscribers. Their accuracy can be demonstrated, and they are not invalidated by the production of selected cases in which the proportionate increase is much greater. The overall percentages compare favourably with the increases experienced generally in industry and business of all kinds since the War. The calculations on which they are based make full allowance for the fact that the pre-war portion of the telephone plant was built and installed at prices much lower than those now ruling. No attempt has been made to set up, at the cost of existing subscribers, a depreciation account which would be adequate to replace the pre-war plant at the present level of costs, when it becomes due for renewal, as it is hoped that present high prices will not be permanent.

ANOMALIES OF EXISTING TARIFFS.

The Post Office has *inherited* a system of tariffs which is full of inequalities and which, but for the War, it would have attempted to simplify and remodel at an earlier date. The existing diverse charges have been built up, largely as matters of expediency, during the chequered career of telephone services in this country, which has resulted from the want of a settled policy on the part of successive Governments. In the early days of telephony many private companies were licensed to carry on the business. Ultimately these fused into one company working under a licence limited as regards time, and interfered with, in its later years, by competing systems set up in various municipalities and in the Post Office itself. It was only two years before the War that the whole control was vested in the Post Office and the way was made clear for the shaping of a truly national system on uniform lines, a work which can only be carried out by several years of well planned and consistently directed effort. There is, therefore, great present disparity between the cost of providing the service and the charges made for it in different places and to different groups of subscribers. For example, some subscribers are making calls at a cost of less than $\frac{1}{8}$th of a penny each, while others are charged a penny per call; the cost, to the Post Office, of providing the service being exactly the same, per call, in each case. Similarly, there are many trunk circuits of only three or four miles in length, providing connexion between adjacent local areas set up in the days of the National Telephone Company, for which a charge of 5*d.* (4*d.* trunk, plus 1*d.* local) is now made, while in other cases communication over local junction circuits, twelve or fifteen miles in length within these areas, is provided at a cost of 1*d.* or 2*d.* per call. Such conditions call urgently for reform.

MAIN ALTERATIONS IN PRINCIPLE.

(1) *Abolition of the "flat rate."*—The flat rate is a single inclusive annual payment which covers the whole of the local telephone service required by a subscriber, *i.e.*, it includes the installation and maintenance of his telephone line and instrument, and the operating and connecting of all calls which he originates. Only about 20 per cent. of Post Office telephone subscribers are at present paying flat rates. This rate is a survival from the early days of telephony, when lines were few and calls infrequent. In its origin the flat rate was not a "tariff" at all. The mere survival of the word "subscriber" shows that it was regarded as a "subscription" for the possession of a privilege, in the same way as membership of a club, rather than as payment for the supply of service to a *consumer*. After telephones began to play an important part in business all telephone administrations wished to get rid of the flat rate, but many have been forced, by pressure of various kinds, to the alternative of juggling with it by trying to circumscribe its application and to adjust it to continuously higher averages of service. The history of such attempts is one long record of failure; it is obvious that no "subscription" system can stand permanently side by side with a "consumer" system. The apparent simplicity of the flat rate has made it fairly popular among business men who have not had occasion to study its results or to consider its equity. Its abolition is hotly opposed by certain subscribers who are large users of the system, and, in view of this, it is necessary to state emphatically that under present-day conditions the flat rate violates the first principles of commercial equity. The clientèle of the telephone system still includes great numbers of subscribers who do not use their telephones to anything like the maximum possible extent, and the extension of the service among such small users is one of the main objects of all telephone administrations. Under the flat rate the same payment is exacted from all users, independent of the amount of service rendered to them, with the inevitable result that the largest users obtain a great deal more service than they pay for, while the smaller users are charged for more service than they receive. Even among flat rate users themselves the amount of service taken varies enormously; the average for the whole country is 3,000 calls per annum, but some subscribers, who receive few incoming calls and whose places of business are open for many hours each day, are now making calls at the rate of 35,000 or more per line per annum. It is clearly impossible to establish a flat rate tariff to cover such cases as these, in which the cost to the Post Office, of giving the service, may exceed

Digitized by Google

£250 per line per annum. The movement against the flat rate, on the part of telephone administrations, has been world wide, and has been specially directed towards it abolition in large business communities; in this respect Great Britain has lagged behind the leading cities of America, where it was abolished several years ago. A great volume of testimony in support of the action now taken by the Post Office could be produced, and the false analogies frequently cited in support of the principle of the flat rate could easily be exposed, but it will be sufficient to quote here a recent summing-up of the subject by one of the leading telephone authorities in America who states that, "wherever and whenever the matter has been carefully and intelligently considered the flat rate has been condemned." Its abolition will produce an immediate and noticeable improvement in the service by reducing the troubles and delays due to overloaded lines.

(2) *Abolition of the "measured rate."*—The term "measured rate," as here used, means a fixed minimum charge for the provision of the telephone, together with the right to originate a specified number of calls, and the sale, in advance, of additional calls in blocks, at a rate decreasing as the number of calls contracted for increases. This type of tariff was originally devised to remedy the manifest inequalities of the flat rate, but its success, from that point of view, is only partial. The development of the technical art of telephony has introduced devices, and traffic handling methods, which make it possible to deal with all calls of similar character at a uniform speed, and in a uniform manner. It costs no more to handle an occasional call, from a small user, than it does to handle a call from a busy user whose line is heavily loaded with traffic. Actually the expense involved per call is liable to be greater in the case of the large user for two reasons, first, because the more continuous engagement of his line leads to a higher proportion of failures of incoming calls for his number, with consequent loss of revenue, and secondly, because large users are generally business men whose calls are concentrated in the business hours of the day and go to swell the "peak load" which is one of the main elements of expense in an exchange system. These considerations more than balance the slight economies in accounting, &c., introduced by dealing with large numbers of calls made by one subscriber.

Since, therefore, it costs just as much to deal with a call from a large user as from a small user, and since the charge per call is, in the Post Office system, the actual cost of the call, without any addition for profit, it follows that the usual business principle of making "a reduction on taking a quantity" is not applicable, and a sliding scale of message fees favouring large users would have no valid justification.

(3) *Adoption of the "message rate."*—By the term "message rate" is meant a uniform charge per originated call applying to all subscribers alike, and independent of any consideration of the total number of calls which each originates. It will have been gathered, from what has been said above, that this is considered to be the only system which can be equitably applied to the conditions in which the Post Office is carrying on the telephone business.

The main charges fall into three portions:—

(*a*) The "Installation Rental"—covering the provision and maintenance of a subscriber's line and apparatus. The sum charged annually is calculated to recoup the cost of supplying, maintaining, and when necessary, renewing the telephone instrument, the line to the exchange, and the small portion of the exchange equipment required for the connexion of the line. In order to lighten the cost as much as possible to the small user, whether in business premises or residences, the addition usually made in order to guarantee payment for a certain minimum number of calls, whether made or not, has been omitted. Payment of message fees (see under (*b*) will only be required in respect of calls actually made, however small their number may be.

(*b*) The "local message fee"—1½*d.* for each originated call. This covers the cost of operating, and the cost of providing and maintaining all the switching plant at the exchange and the junction circuits and equipment required for intercommunication with subscribers connected to other exchanges in the area covered by the local fee.

(*c*) "Trunk fees"—based upon mileage beyond the radius of local intercommunication. These fees cover the cost of the lines, exchanges, and operators, proper to the trunk system, and are charged additionally to the local fee for each call.

It shqld perhaps be mentioned that the shorter trunk circuits are operated in exactly the same manner as local area calls. It is only in the case of "long-distance" calls that a subscriber is requested, after making a call, to hang up his receiver and wait until the operator informs him that the trunk is at his disposal.

(4) *Mileage basis of charge.*—Before the year 1912, when the local telephone systems of the country were transferred from the National Telephone Company to the Post Office, it was necessary to have a system of local areas, within which the National Telephone Company operated, and to limit the function of the Post Office Trunk System to the provision of communication between exchanges in different areas. This, as already mentioned, necessarily led to considerable inequalities of charge, as many inter-area circuits, for which trunk fees were charged, were much shorter than some of the local junction circuits within the areas. The remedy of this anomaly was put in hand shortly after the transfer, but had to be suspended on account of the war. It has now been embodied in the new system of rates and all communications will be charged for on the simple mileage basis given in the schedule of charges. The local fee (1½*d.*) will cover all calls within a radius of 5 miles from the exchange, and in London the range of local fee communication will be further extended to give all exchanges, within 10 miles of the centre, local fee communication with the whole central area of the city. In Glasgow, Manchester, Liverpool and Birmingham a corresponding extension will be granted to all subscribers within 7 miles of the centre. For these extended facilities an additional charge is made of £1 per annum in London and 10*s.* per annum in the other cities mentioned.

COUNTING THE CALLS.

The favourite journalistic statement that a "horde of new officials" will be required to enumerate the calls made by former flat rate subscribers is based upon complete misapprehension. More than 80 per cent. of existing subscribers already pay in accordance with the number of calls they make. The electrical meters used for the purpose already exist on all the lines at large exchanges and as a matter of fact the calls made by flat rate subscribers are already counted in just the same way as the others. The operation, which consists in the mere pressing of a button at a certain stage in the connexion, is so simple that it is more economical to make the operator follow the same routine for all calls than to ask here to discriminate in the treatment of connexions asked for by different classes of subscribers. The cost of regularly reading the meters and rendering accounts on the basis of calls, to subscribers now on the flat rate, will be insignificant in comparison with the additional revenue derived from the equitable system of charging for the service given.

The statement that these subscribers will themselves be involved in great expense in making a counter check is also fallacious. Very few subscribers who now pay according to their calls take the trouble to do so. They trust in the accuracy of the record made at the exchange, and the Post Office is always ready to show them the details of the whole operation and to demonstrate the efficiency of its arrangements for enumeration. When one bears in mind the abundant opportunities which generally exist

Digitized by Google

for the use of a telephone outside the knowledge of the responsible subscriber, the number of complaints or disputes is remarkably small.

CONSIDERATION OF THE SMALL USER.

It is not easy to speak of the "encouragement of the small user" at a time when the costs of all kinds of services are at their present level, but it can at least be said that the Post Office fully realises that the future development of the Telephone Service is largely dependent upon the attraction of new subscribers whose initial use will be small, and that it has taken every possible step to reduce the payment by such subscribers to a minimum. The frequent statement that the Post Office has shown a callous disregard of the future of the telephones, by setting up a scale of charges prohibitive to small users, is quite devoid of foundation. The new tariff will help small users—

(1) by making the large user pay the fair charge for the service he obtains, thus enabling the small user to be served at cost price.

(2) By abolishing the minimum charge for calls, whether used or not. The Post Office is taking considerable business risk in this connexion but it trusts that sufficient calls will be made to cover the heavy cost of switching plant which has to be installed in readiness for service, and which the payments received as message fees have to cover.

(3) By the system of quarterly instead of annual advance payments, which will reduce the initial outlay and spread the charge more evenly over the year.

THE FALLACY OF EXTREME CASES.

The great anomalies in the existing rates make it particularly easy to make a public parade of selected cases in which the proportion of increase is far in excess of the averages already quoted. It is obvious from what has been said above, that the cases frequently cited to show increases of 300 or 400 per cent. are perfectly genuine. A subscriber who goes on making 30,000 calls per annum on one line will in future have to pay about £187 a year, which is more than 9 times the present London flat rate tariff of £20. But the meaning of this is simply that such an individual, after the first 2,000 calls, is now getting the whole of his service free, or, more correctly, he is getting it at the cost of his fellow subscribers and the general taxpayer.

Equally misleading and extravagant cases could be quoted on the other side. For example, a subscriber at Edgware at present pays 5*d*. to ring up Central London or even to ring up the adjacent localities of Harrow or Finchley, and *vice versa*; a subscriber in Glasgow pays 5*d*. to ring up Paisley, and a subscriber in Manchester pays 5*d*. to ring up Oldham or Ashton-under-Lyne. *All these charges will in future be* 1½*d*. The subscribers on no less than 30 exchanges outside the London County Council boundary, who now pay a fee of 2*d*. per call for all communications outside their own exchanges, will in future be charged only 1½*d*. for all calls to exchanges in Central London (10 miles diameter) as well as for calls to all exchanges within 5 miles of their own. It would be equally reasonable to attack the Post Office because, at a time when revenue is deficient, it is wasting money by making these reductions.

THE SUGGESTION OF AN EQUAL OVER-ALL INCREASE.

Large users are pressing upon the Postmaster-General the alternative of raising the necessary additional revenue by making a uniform percentage increase on all the present charges. Such a course would enable these large users to continue to receive service at the cost of other people who would pay more than their fair share. It will be recognised from what has already been said about the inequality of the present charges that such a course is impracticable. It would indeed be utterly unprincipled. It was perfectly obvious to the Post Office that, before the large additions necessary could be made to the rates, it was essential that their basis should first be made equitable, as between one part of its clientèle and another. Now that an equitable adjustment has been framed it will be easy and convenient to deal with future changes of tariff by a general percentage adjustment. Let us hope that the future trend of costs will permit such adjustments to be in the *downward* direction!

REDUCTION OF EXPENSE BY DEVELOPMENT.

An argument frequently encountered is that the Post Office should seek its additional revenue by development of the system and not by raising its charges. This argument is brought forward by business men who are applying the common principles of their own business to a business of quite a different character, the governing conditions of which they do not understand.

Development, which is of the nature of technical progress is, of course, a factor which has in the past operated powerfully in reducing the cost of telephone service and which will certainly continue to operate in the future. But the kind of development represented by mere increase in the number of subscribers does not reduce the cost per line or per call. It brings in certain economies which are always a feature of extended business and of mass production, but the savings introduced in this way are neutralised by the increased technical complexity of the switching plant and of the operating arrangements required to provide intercommunication among a large number of subscribers. The technical features of the service which bring about this result are too complex for description in a short general article, but the *fact* is demonstrated by the experience of all telephone administrations. For example, the accounts published by the late National Telephone Company show that the expense per telephone station remained practically constant through years which witnessed great expansion of the system. Another fact which the public can readily verify for itself is that in all countries telephone rates have hitherto been higher in large cities, where the number of subscribers is great, than those charged in less populous towns and rural areas where the amount of development is smaller.

THE INFERENCE OF INEFFICIENCY.

Space does not permit this question to be dealt with here. Much might be written to explain the task of the Post Office when a congested and largely obsolescent telephone system was placed in its hands in 1912; the steps taken to reconstruct and extend it; the inadequacy of the time between the transfer and the outbreak of war; the part taken by the Post Office staff in the war and its effect upon the telephone system; the extreme difficulties and delays associated with post-war reconstruction from which the Post Office, and the contractors upon whom it depends for the supply of relief plant, suffer in common with the general industry of the nation; the improvements effected since the early days of the Armistice; and the comprehensive and scientifically sound plans upon which the future development of the telephone system has been mapped out and is being energetically pressed forward. It could be shown that the proposed increases in rates compare favourably with those which other administrations abroad are being forced to adopt, and compare favourably with the great increase in expenses of all kinds which has fallen upon the telephone organisation. It can fairly be claimed that there is no evidence in all this of inefficiency and that on the contrary the Post Office staff represents an exceedingly efficient body of public servants who work much harder and more disinterestedly for the common good than do most of their critics and detractors. It may be that the mind of the public has been so far abused upon this subject that it can only be reassured by the appointment of a Royal Commission to investigate the whole conduct of the business. The Post Office telephone department would warmly welcome such an opportunity of submitting itself to fair and intelligent investigation, with the one reservation that much time and energy would thereby be deflected from its present and pressing labours in the work of reconstruction and progress.

THE BAUDOT—XVIII.

BY J. J. T.

UPON the end of the axle X^1, which projects from the receiver casing is fitted, friction tight, a metal sleeve S (Fig. LIII, see also Fig. XLIX), and on to this sleeve is *fixed* the impression wheel V^1 (Figs. XLIX and LIII, &c.). The periphery of this wheel is equidistantly grooved to the extent of 31/40 by, 31 slots, corresponding to the number of slots upon the combiner discs T, T^1 (Fig. XLIV, &c.). The remaining 9/40 of its circumference presents an uncut edge. At the *back* of V^1 upon the axle X^1 (Figs. L and LIII), is firmly fixed a powerful catch E, by means of a binding screw *e* and to the back of V^1 is fitted a powerful steel spring-clutch C which engages with the slot cut in the catch E (Fig. L). This forms the mechanical union between X^1 and V^1 and by means of which the latter rotates. Should an obstruction to the movement of V^1 and its auxiliary mechanism present itself, damage to the apparatus would be prevented by the shock of sudden stoppage being absorbed by the clutch which would release E permitting the latter and the axle X^1 to rotate free of V^1 and its appurtenances.

Fitting easily upon the sleeve S (Fig. LIII) is another sleeve, B. To the extremities of this sleeve are fitted (*a*) at the outer end the typewheel W and (*b*) at the inner end a "spider" form of lever, known as the inversion lever A (Figs. LXIX and LIII). Thirty-one fortieths of the typewheel W are occupied with engraved letters and figures or letters and signs alternately placed thus, A 1 E 2 Y 3, &c. Each figure or letter, therefore, only occupies 1/80 of the circumference. There are actually 29 letters, and 29 figures or signs, the remaining space being occupied by two blanks respectively used as letter or figure spaces or shift keys. As with the impression wheel so with the typewheel, the remaining portion of its circumference presents an uncut edge affording sufficient space for the clearance of certain moving parts when actual printing is not taking place.

The typewheel W (Fig. LIII) is fixed to the shoulder *a*, *a*, of the sleeve, B, B, by means of three screws, two *y*, *y*, of which only are shown. A fourth screw, Y serves, together with its washer to maintain V^1, W, &c., in their position on the axle X^1. Ovoidal apertures through the face of W permit certain minute adjustments of W upon the shoulder *a*, *a*, according to whether movement to the right or left is needed to give more or less accentuation to one side or the other of the characters to be printed. This position obtained the screws *y*, *y*, are firmly screwed home.

When the typewheel W, and the lever A are fixed upon the sleeve B (Fig. LIII) they complete what may be considered as the typewheel combination. This as one solid piece may now slide over the first sleeve S, and when pressed into position against the *front* of the impression wheel V^1 the "spider" A should take up its position on V^1 in the following relation to the inversion plates *a* and *b* which are fixed upon it. The two short prongs of A fit easily between the claw-like openings of respectively *a* and *b*. These plates are capable of movement on the axes of the counter-sunk screws which bind them to V^1. At the same time the longer prong *c* of A fits in between the limiting studs 1 and 2. The limiting angle of movement permitted to *c* by these studs is $4\frac{1}{2}°$. The prong *c* is sloped on both of its sides to a hardened steel point and by reason of a small lever *f* pivoted on B, aided by a spiral spring the entire lever A is thus held in position either against stud 1 or 2. The lever *f*, its spring and holder B are also permanently fixed to the front of V^1, and the inversion plates *a* and *b* are so arranged that a portion of either one or the other must intrude itself upon respectively the 14th or 31st slot of the impression wheel V^1, thus partly

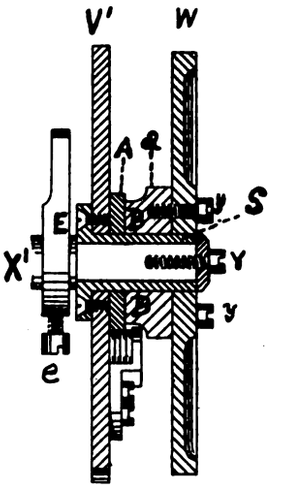

FIG. LIII.

closing the gap. If then the tooth of the impression cam be released in time to engage itself with the fourteenth slot—which should happen when the fourth electro-magnet of the receiver is energised—the inversion plate *a* would be thrust out of the tooth and given a twist in the direction of the arrow (Fig. XLIX) *c* being forced under *f* and thrown against stud 1. If the fifth electro-magnet were energised the impression cam would engage with the 31st slot when the inversion plate *b* would be forced back, the position of *c* reversed and the inversion plate *a* would again obstruct the 14th slot ready for the next letter-shift. The dotted lines at D show the angular movement of *c* which as already stated is $4\frac{1}{2}°$. This means that as the *typewheel* W *actually forms a solid part of the lever A*, both being fixed to the sleeve B, which slides *on to the sleeve S*, therefore when the angular displacement of the "spider" A by $4\frac{1}{2}°$ takes place the *typewheel* W itself has moved an equal distance in relation to the impression wheel V^1, *i.e.*, 1/80 of the periphery of the typewheel.

The wheel V^1 has, in turn, a definite and fixed position upon the axle of the receiver, which position having been determined by previous adjustment is finally fixed by means of the catch E and the binding screw *e*. The clutch C on the back of V^1 (Fig. L) continues the relationship and the engagement of the inversion-spider lever A (Fig. LXIX) carries on the mechanical harmony and conveys it to the impression wheel. The mechanical relationship desired and by this means attained is that Ca (Fig. LI) shall be released on the receipt of any given combination of signals, at just that particular fraction of a second of time at which the typewheel shall be in the correct position to print the equivalent letter or figure.

(*To be continued.*)

HOLIDAYS.

MR. J. W. FEWTRELL, of the Engineer-in-Chief's Office, is arranging a party to Switzerland, to leave London on June 3 and to arrive back on Sunday evening June 19. The cost from London to Meiringen and back, including hotel accommodation, will be £19 10*s*. Mr. Fewtrell will be happy to give further particulars.

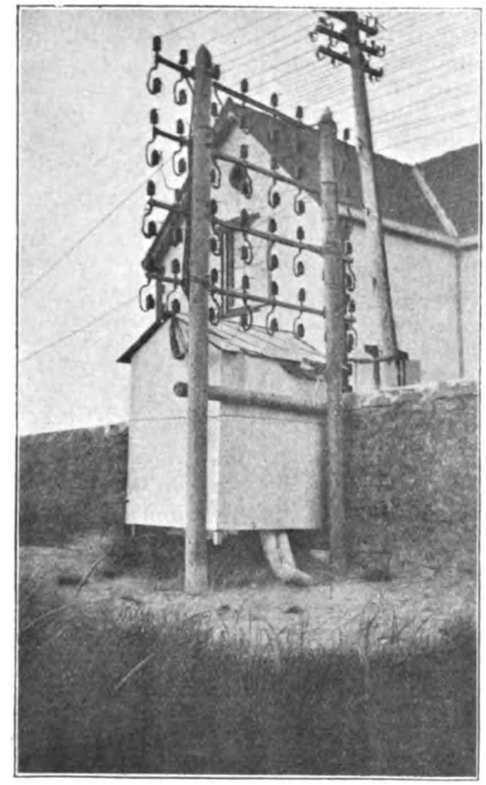
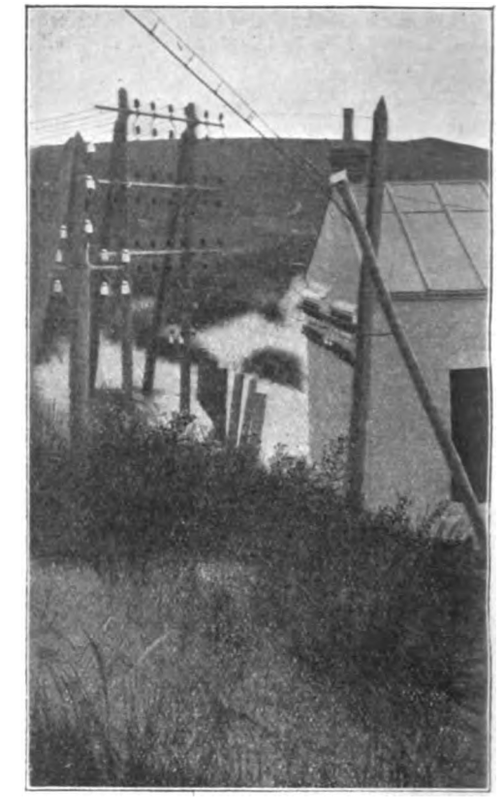
WHERE THE WIRES DIP INTO THE SEA.

THE place where the land lines step down from their poles to dip under the ocean must always excite the sentimental if not the technical attention of each one of us interested in the twin crafts of telegraphy and telephony, and especially those of us who are closely connected with long distance lines, including Anglo-Continental communications. To such it is thought the accompanying eight photographs will appeal, for here may be seen some typical submarine cable huts as erected (1 to 4), on the French coast, and (5 to 7) on the English coast.



Nos. 1 and 2 show back and front views of the Audresselles cable hut, of comparatively recent construction, one which in fact became active during the late war period. It is probably the last constructed landing place of an Anglo-French submarine telegraph cable as in contrast with Gris Nez (3 and 4) to which spot the very first English Channel cable was laid from Dover in 1851 under the supervision of the brothers J. W. and Jacob Brett. It is not maintained by the writer that the present hut is the identical building of 1851 !

A cursory glance would at first sight rather impress one with the comparative frailty of this type of French cable hut, but the proof of the pudding is evidently in the eating thereof, for both buildings, to the writer's knowledge, have effectively withstood scores and scores of storms with proved success even though the overhead wires have at times utterly failed.



The English cable huts, Birling Gap (No. 5), St. Margaret's, Dover (No. 6), and Dumpton Gap, near Broadstairs (No. 7) have a look of greater stability and permanence, which is a feature of most of these buildings around the

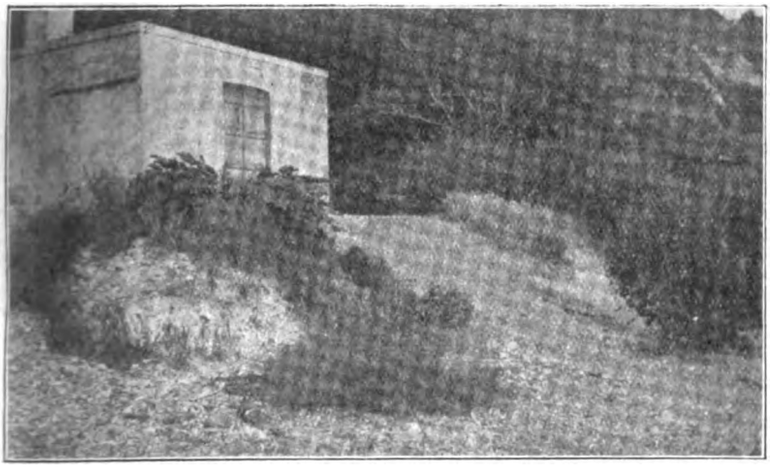
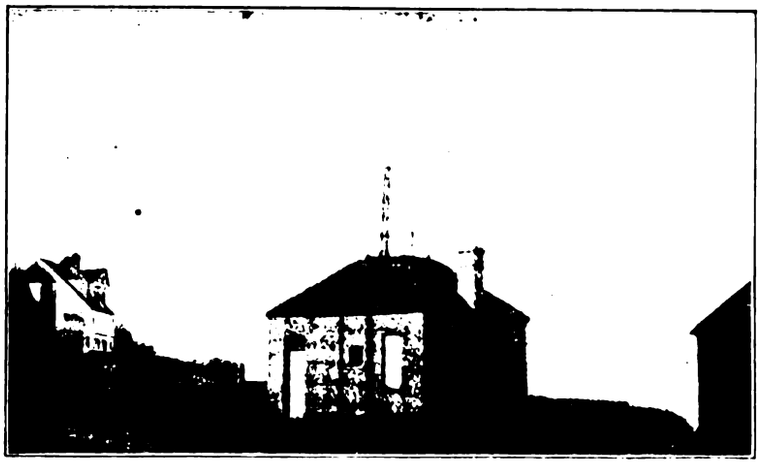
Digitized by Google



coast of the British Isles. The nature of the two coastlines, French and English, also offer pictures of contrasts, the sand dunes of the Audreselles district contrasting with the chalk of the Kent and Sussex cliffs.

All the land wires led into the St. Margaret's cable hut on the English side are on the underground system. Only the war prevented the complete extension of this method of construction to other routes and even in the latter cases post-war construction is gradually recovering ground. It is confidently hoped that before very long all Anglo-Continental land lines in England will be of underground construction, and that, in addition to the higher efficiency thus obtained and the comparative immunity from weather faults, the aesthetic eye of public critics will be less and less offended by the sight of poles and wires across the landscape!



During hostilities it became necessary to have a watcher on duty day and night at one of these huts. It speaks volumes for the endurance and capacity of the lower ranks of the Engineer-in-Chief's Department that a telegraphist-lineman carried out the necessary duties with faultless courage, on stormy nights the waves sometimes washing completely over the hut; at calmer times enemy air-craft dropping numerous spherical objects in the near neighbourhood.

REVIEW.

"*Sindri.*" (*Reykjavik, pp.* 48).—We have received the first number of an Icelandic magazine entitled *Sindri*, which we take to mean "Sparks." It is the organ of a technological society in Iceland, or rendered literally, work-knowledge-fellowship, and is edited by Otto B. Arnar, at one time editor of *Electron*, the Icelandic telegraph and telephone journal. Amongst the articles are a sketch of the life of Oersted, with an abridgement of his "*Experimenta circa effectum conflictus electrici in acum magneticum*," first published in 1820; a sketch of the history of Letters Patent from the Middle Ages to the present time, and papers on mining and gas lighting. The magazine is well got up and illustrated with photographs, and is altogether an enterprising and interesting production.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. MARCH, 1921. No. 72

NO CHARITY REQUIRED.

WE imagine that any unsophisticated person who turned over the newspaper files of the last few months would carry away the impression that a very real and widespread indignation existed in this country on the subject of the new telephone rates. Not only would it appear to him that the great London and provincial daily papers and the journals published weekly in the chief country towns were almost unanimous in condemning those rates, but he would find even such papers as the *Grocers' Journal*, the *Sunday Sportsman*, the *Shoe and Leather Record*, the *Furniture Record*, and papers unheard-of by the lay reader, taking up the cudgels on behalf of an oppressed public. He might be excusably ignorant of the precise meaning of the expression "Telephone Ramp," but such captions as the Telephone Iniquity, the Telephone Scandal and Telephone Tyranny would leave little doubt in his mind that something in the nature of an injustice was about to be perpetrated on the telephone-using public.

If, however, our unsophisticated newspaper reader could be enlightened as to the true inwardness of all this seemingly white-hot indignation, he would perhaps be undecided whether to wonder most at the power of the Press or the marvellous unanimity with which that power can be employed in the interests of a limited section of the public. He would learn with surprise that the flat rate subscriber represented only one-fifth of the telephone users, and that to maintain that rate, loudly proclaimed to be indispensable to the interests of the "business man," either the other telephone subscriber must be overcharged or the burden must fall on the taxpayers—with what propriety may be easily calculated when it is remembered that probably not more than one-tenth of their number are telephone subscribers. He would learn also that the clamorous flat rate subscriber does not include in his numbers some of the largest users, who pay at the private branch exchange rate. But what we think would astonish him most would be the knowledge that the indignation of the small user was being successfully fomented to combat his own interests. This to our mind is where the disingenuousness of the Press campaign is most gross and palpable. It is obvious that telephone rates must be raised to cover the enormously increased cost of providing the service, which have resulted from the war and its sequelæ, and to do this the fair and logical principle has been adopted of making each subscriber pay strictly according to use. The small user will pay on the average about 50 per cent. above the present rate—an increase infinitely less than that he pays for almost every service or commodity with which he is supplied by private enterprise. And yet the champions of the flat rate subscriber in the Press have almost persuaded him to make common cause with them, and have contrived to stimulate in him an indignation at "monstrous charges" which as a reasonable man he would never have felt had he considered the increased rates purely on their merits. It is an ironic fact that the small user's interests are entirely unrepresented, except by an iniquitous Department. All those bodies which provide the mouthpieces of criticism, the Press, the Municipalities, the Chambers of Commerce and suchlike, are composed mainly of "large users." Those constituents who bring most pressure to bear on their Members of Parliament are again of the same class; even (or, should we say, of course) the "Middle Class Union" lends its aid to the same interest, although it is obvious that if the taxpayer is not to bear the burden of providing flat rate service below cost price—the small telephone user must do so.

At a representative meeting of the City Corporation on Feb. 14 it was said with acclamation that no charity was asked. Yet if the present rates were doubled and the business man was allowed to retain the inequitable flat rate on those terms, he would still be subsidised to the extent of something like £800,000 a year by the small user or by the taxpayer. He does not ask for charity, but he is not above accepting it. Cicero says somewhere: "*Caritate benevolentiaque sublata omnis est e vita sublata jucunditas*," which we may translate: "When charity and benevolence are removed all the delights of the large-user's life disappear." For there is no third course.

HIC ET UBIQUE.

PARLIAMENT has promised to appoint a Select Committee "to enquire into the organisation and administration of the telephone service." To this was added, at Sir F. Banbury's suggestion: "and the method of making charges." On behalf of the Government, the Attorney-General agreed to this suggestion, which, he said, was implicit in the terms of the proposed reference. Some of the newspapers indulge in unusually chastened jubilation at what they term the "climb down" of the Government. They regard the offer of a Select Committee with suspicion, for while its recommendations are uncertain and unknown, the disappearance of the flat rate on April 1 is a certainty.

THE number of telephones in the United Kingdom at the end of 1920 reached a total of 985,600, *i.e.*, 970,093 on the Post Office system and about 13,000 and 2,500 on the municipal systems

Digitized by Google

of Hull and Guernsey respectively. Last year the total was 911,909. London had 339,804 (as compared with 311,350 in 1919); Glasgow 43,212; Manchester 41,746; Liverpool 40,791; Birmingham 26,188; Edinburgh 18,809; Sheffield 14,063; Leeds, Bradford and Newcastle-on-Tyne each over 13,800; Dublin over 12,000, and Bristol, Belfast and Nottingham each over 10,000. The last 3 are new accessions to the rank of towns with over 10,000 telephones, which now, including Hull, number 15.

THE *Saturday Review*, which moves in a narrow and select compartment of the great world, has the following paragraph :—

The telephone operators have squeezed out of the Government four and a quarter millions for war bonuses for the year 1920-21. Result, four millions sterling loss on the year's working. In order to prevent this loss falling on the general body of taxpayers the Government proposes to raise the telephone charges. Who are the wasters, the Government or the rapacious and inefficient telephonists ? Stop the war bonuses and this particular waste will stop. War bonuses of four and a quarter millions are the cause of the telephone ramp. Civil servants and miners are determined not to bear their fair share of the cost of the war.

Why only miners of all the industrial world are associated with civil servants we are left wondering. Of course "telephonists" includes assistant secretaries, engineers, surveyors, and everybody else in the Service in the catholic mind of our contemporary. We refrain from comment; a lively political excursus on post-war economics is out of our province.

THE financial press has been turning its attention to the German Telephone Service and the sorrows of the German business man. We learn that an additional charge of 80 marks (nominally £4) per subscriber has been made. We are without further official information on the subject than that which we published in our December issue, but it rather looks as though instead of a proper revision of the rates as there foreshadowed an all-round increase of 80 marks had been levied. This is the kind of remedy so many of our critics have advocated for the British deficit—and yet the German subscriber is not pleased. He is making an outcry against the new extortion. Of course all his ills are ascribed to the "Socialised" service—nothing is said of post-war troubles and 2,000 per cent. increases in the price of materials. The correspondent of the *Financial News* tells us that telegraphic rates have been increased a hundredfold! We find it difficult to believe that a 6*d*. telegram costs £2 10*s*. in Germany. But perhaps a "hundredfold" in the financial world only means 100 per cent.

"WHEN Rowland Hill introduced penny postage into England," says the same oracle, "forthwith the Post Office receipts (not number of letters carried, mark, but the receipts) increased in stupendous proportions." We do not know how to express "forthwith" in terms of years, but as a matter of fact the first year actually involved a loss of revenue of over a million, and it took the receipts nearly 12 years to recover. Thus is history—of a kind—pressed into the service, and an instructive moral shyly pointed from an imaginative tale.

WHEN rates are high in Sweden, the lot of the newspaper telephone critic is to be commiserated. The *Star*, however, still lives in a pre-war world and talks of a £2 15*s*. rate. The case of the *Express* is harder. They sent a representative to the Swedish Chamber of Commerce who, it is reported, informed him that you could get unlimited calls for £7 in Stockholm. As a matter of fact the £7 1*s*. rate applies to private houses only, and includes a limited number of calls. The lowest rate for business premises (with a limited number of calls again) is £10 9*s*.

BUT, in the agitated mind of the newspaper world, the whole of Europe is devastated by telephone "ramps." The picture which we reproduce from the Viennese comic journal *Kikeriki* is accompanied by the legend: "The colossal increase in rates will make one section of the public happy." That section, of course, is the telephonists who, it will be seen, are reading, sipping coffee and jazzing. Yet, although according to comic journalists, telephonists were ever thus, the *Yorkshire Evening News* deduces from the picture that "Austria is also in the grip of a 'phone ramp."

The shortness of the young ladies' skirts in the picture seems to have some graphic relation to the lowness of the calling rate. Strangely enough, *London Opinion* has a picture to exactly the same effect as *Kikeriki*.

IT is evidently difficult to gauge the telephonic development of the new European states. Before the war there were about 45,000 telephones in Russian Poland, 50,000 in German Poland, and 6,000 in Austrian Poland, say 100,000 in all. Yet the official figure of the present development of Poland is 36,000. On the other hand the Czecho-Slovak provinces of Austria had about one-third of the pre-war total number of telephones in Austria, plus a few thousand in Hungary—about 60,000 at most. An estimate on these lines, slightly reduced to 54,000 to allow for war conditions, was given in the article which we published last month. Official figures are, however, now to hand which give the total number of telephones in Czecho-Slovakia as 138,843!

THE following letter received by an Irish District Manager of Telephones has something in it of fluid as well as fluency. We refuse to commit ourselves to a characterisation of it as "typically Irish" :—

Dear Sir,—A friend of mine is Mr. ——, who is one of the largest merchants in W., and belongs to one of the oldest families. Having made not much money in business, he has made up his mind to go back to the land, that is, he has bought a farm at a place called Bally— —, with a castle attached, if you please, and he is now working a farm of 250 acres. In addition to this he has also a coal yard, corn stores, and general business here in town. His life is spent not so much in making money as spending it, and he cannot conveniently do this without having the two places, but occasionally it would be very handy for him to remain in Bally— — on Mondays after the week end, although, strictly speaking, he is a teetotaller. In order to do this he cannot carry on without the telephone, and I am sure you will have a telephone installed in his house at Bally— —, which is only three hundred yards from the wire running to K. He is, of course, prepared to pay the cost, which could not be very much. When you kindly put in the telephone and ring up Bally— on your visits down here, you will not be hungry, thirsty or without a bed, or anything you want, for the hospitality is the same as that of the Monks of Cappoquin, only it costs you nothing, and you need not pray, though we hardly ever do anything here except pray for poor Cork, and also that W. will never be as bad.—Yours truly,

Digitized by Google

WIRELESS COMMUNICATIONS.*

BY LIEUT.-COLONEL C. G. G. CRAWLEY, R.M.A., M.I.E.E.
(Deputy Inspector of Wireless Telegraphy.)

WIRELESS communications may be placed in two divisions: mobile and fixed. Mobile communications are those with ships and aircraft, fixed communications are those between fixed stations. It is fairly obvious that mobile communications are by far the more important so far as wireless is concerned, for as soon as the mobile craft is out of visual touch there is no other means of communication, whereas between fixed points there may be land lines or cables.

Communication with ships is governed internationally by a Convention dating from 1912. This Convention is naturally much out of date, and its revision has been considered provisionally during the last few months by an Inter-Allied Conference in Washington. The next Convention will probably be held this year. Ships' communications may be divided into those of the Navy and of the Mercantile Marine.

Naval.—In the Navy the chief point which requires consideration is Selectivity. The vital importance of this will have been noticed in the reports recently published of the Battle of Jutland, where, owing to the jamming of one particular signal the whole course of the battle was materially altered. Besides the elimination of jamming from enemy ships, special selectivity is required to prevent jamming from one's own ships; for instance, a battle fleet in close formation must be in wireless touch simultaneously with coast stations, cruisers, destroyers, submarines and aircraft, so that selectivity in the reception of messages from these various sources becomes absolutely essential. In the *Queen Elizabeth* at the present moment there are 10 complete wireless installations and 60 operators. This fact alone shows how necessary it is to have great selectivity in the design of naval sets. As a matter of interest it might be mentioned that submarines when just submerged can intercommunicate by wireless up to distances of about 10 miles, and if submerged 10 feet, up to distances of about 3 miles. On the surface of course the distance is largely increased up to, say 50 or 100 miles. The navy has at present 17 coast stations abroad for the purpose of communicating with Naval Ships and to a certain extent with ships of the Mercantile Marine. Of these stations, only two, those at Malta and Gibraltar, were in being before the War, and if the other 15 which are distributed over the Empire had been working at the commencement of the War, there is little doubt that many millions of pounds would have been saved by the speedy rounding up of German raiders. The naval stations at Ascension and Falkland Islands are 100 K.W. and 150 K.W. in power respectively; nearly all of the others are exactly similar to our station at Stonehaven, viz., 30 K.W. spark and 25 K.W. arc.

Mercantile Marine.—In the Mercantile Marine, selectivity is not of such great importance because of the arrangements made for receiving the Distress Signal. This signal is always sent on the 600 metres wave, so that all ships are compelled to keep watch normally on that particular wave, thus making the conditions quite different from those governing naval communications. Recently another wave-length has been arranged for clearing passenger traffic, and the Post Office has erected a station at Devizes for communicating with ships on this particular wave. The range between ships and Devizes is about 1,200 miles, and between ships similarly fitted the range is about 1,000 miles. The ranges obtained by ships on their nornal sets are a few hundred miles, with coast stations, according to the installation fitted. In this Country every passenger ship and every ship of 1,600 tons gross and upwards must now be fitted with wireless telegraphy, which means that at present about 3,200 British ships are fitted. These regulations apply equally to the foreign ships which visit British ports. The installations on ships are inspected by the Post Office. At present only 10 Inspectors are available, but it is hoped that this number will be shortly increased The cost of a ship's set is about £400 or £750 with £30 per annum maintenance, according to the set. There are now a certain number of ships—about 20—fitted with Direction-Finding apparatus and the number so fitted will no doubt be largely increased as soon as the advantage of having such a set is realised generally. Under good conditions the error of direction obtained by this apparatus fitted in a ship should not be greater than 2 degrees. Duplex is not fitted in ships, as it is not yet a practical proposition to do so. High speed apparatus is not fitted because the traffic at present does not call for it, but there is no reason that such apparatus should not be fitted in ships just as at fixed stations. Wireless telephony is not yet fitted in any merchant ships, but is being fitted in both the United States and the Japanese Navy. Our own Admiralty is not at all inclined at present to fit wireless telephony generally in naval ships.

Mercantile Operators.—All operators for merchant ships are examined and given certificates of proficiency by the Post Office. At the present moment there are about 5,000 such operators employed. Last year we examined about 3,500, half of whom passed the examination. Altogether there are about 12,000 on our books. These operators are trained at 40 private schools scattered throughout the United Kingdom, and our examining staff consists of 5 Assistant Superintendents and 2 Overseers with two additional Assistant Superintendents at Headquarters. These latter two deal also with "Complaints." These "Compaints," of which we receive about 120 a month, are sent in by ships and shore stations on the matter of irregular working. It will be understood that any irregular operating in wireless telegraphy is far more serious than in line working because the unnecessary interference and waste of time caused by such irregularities are very great owing to the fact that nearly all signalling is carried out on the same wave-length In addition to operators we examine about 120 watchers a week and there are now about 600 on the books. The watcher is quite a new institution resulting from the Merchant Shipping Act of 1919. The Rules in connection with this Act laid down that First Class ships (200 persons or more) must carry 3 operators; Second Class ships (50 persons or more) must carry 1 operator who keeps watch at scheduled times and 2 watchers; Third Class ships must carry 1 operator, who keeps watch at scheduled times. The watcher is only required to be able to recognise the distress and the safety signals when received through interference, and to know when the receiving apparatus is functioning. Any member of the crew may, if qualified, carry out the duties of a watcher. As soon as automatic apparatus for registering the distress signal is invented, and approved by the Post Office and the Board of Trade, the necessity for carrying watchers will lapse. These new regulations for watch-keeping on board ship are an admission of the principle of the 8-hours day, as previously ships with 2 operators only carried out a continuous watch.

Coast Stations.—There are 12 coast stations distributed around the British Isles. These stations are Post Office stations used solely for communication with ships. In addition the Post Office has four point-to-point stations, namely, Stonehaven, Caister, Oxford and Northolt, the last two being under construction. There are also six emergency Post Office stations not normally manned, but used when cable breakdowns occur; and in addition the Engineer-in-Chief has three purely experimental stations. The coast station traffic is at present about 2½ million words a year, two million being at the full rate and the remainder at a reduced rate. In addition, ships communicate their position, course, speed, &c., to the nearest coast station and this information is passed on to Lloyds'. The coast stations also broadcast warnings of mines, derelicts, ice and gales—about half a million words a year, which would bring in a revenue of about £15,000 if charged for at usual rates. In the last six months the full rate words were 1,000,000 compared with 700,000 in the previous six months, so that the coast station traffic is certainly increasing rapidly and in fact the service is now nearly paying its way, although no increase in charges has been made. There are elaborate arrangements at the coast stations for reporting to all proper authorities in the quickest possible time any distress signals received, and there has never been any serious complaint at the action, or want of action, of a coast station in this most important matter of dealing with distress signals.

At present if you want to send a message to a ship, you must state the coast station through which the message is to be sent. If you do not know the coast station and if the Counter Clerk does not wish to be helpful, the matter may probably end there. This is certainly unsatisfactory, and it is to be hoped that some day the public will be able to hand in a message for a ship at any Post Office in the United Kingdom without knowing or caring through what coast station the message will be sent. All this, of course, would saddle the Department instead of the public with the responsibility, but the resulting increased traffic should disarm any criticism from this point of view. The charges for messages are at the rate normally of 11*d.* a word, *i.e.*, 6*d.* for the station, 4*d.* for the ship and 1*d.* for the inland telegraph. The staff at a coast station consists of 1 overseer, 8 or 9 operators and 1 labourer. There are thus always 2 operators on watch, 1 on the wireless and 1 on the land line, &c. The cost of a station's staff at present rates is about £3,500 a year. The operators employed on this work must be expert wireless operators as the signals are nearly always jammed to a greater or less extent, and the senior operator on watch is in charge of the whole station and controls the traffic in the absence of the officer-in-charge. At present the Post Office wireless operators are recruited from the Department's land line staff. They are attached as probationers for 2 years to a coast station, after which if they pass in technology, French and German, they are accepted on the staff and are considered capable of taking charge of a station in the absence of the officer-in-charge. The capital cost for an average coast station is difficult to estimate at the present time, but as £3,500 might be taken as a pre-war figure, £10,000 might perhaps be given as an estimate at present costs.

Direction Finding Stations.—There are at present 9 D.F. stations in the British Isles, all under naval control. The number may very likely be reduced in the near future and it is possible that the Navy may wish to transfer the control of these stations to some other Department. The United States have about 50 of these stations working and 30 being erected. France has 16, 9 being on the North Coast and Germany has 4 on the North Sea. We are, therefore, rather behindhand in the number of D.F. stations in this Country, but we are well to the fore in charging 5*s.* for each bearing, whereas none of the other countries make any charge.

Aircraft.—There are only about 12 commercial aeroplanes at present fitted with wireless telegraphy and these are fitted with wireless telephony also. The ideal of course is for aircraft to communicate by wireless telephony with a land station where they can be directly connected to the telephone service of the country, and some fairly successful tests in this direction have already been carried out. All aircraft installations and operators are licensed by the Post Office on the recommendation of the Air Ministry.

WIRELESS TELEPHONY.

The advantages of wireless telephony are that the operator requires no knowledge of telegraphy and that much greater speed is attainable in communi-

* Summary of an Address given before the Telephone and Telegraph Society of London, Jan. 17, 1921.

cation. In wireless telephony there is no distortion similar to that which occurs on land lines, a most important fact for long-distance working. These advantages, however, are at the moment outweighed by the disadvantages. The great disadvantage is non-selectivity; that is to say, that wireless telephony is more open to jamming and being jammed than wireless telegraphy. Also the power to obtain a certain range in wireless telephony is about twice as great as the power required to obtain the same range in wireless telegraphy. At present, also, simplex wireless telephony only is in use owing to technical difficulties in arranging for listening-in as in the case of line telephony. This last trouble is no doubt a temporary one, and the United States Navy is already fitting some sort of duplex wireless telephony in their ships.

As regards point to point telephony, the first long distance test of note was carried out in 1908 between Brant Rock in the United States and Machrihanish in Scotland. No great advances, however, were made in wireless telephony until the introduction of the thermionic tube as a transmitter in 1913. In 1915 Arlington station near Washington communicated by wireless telephony with Eiffel Tower, 2,300 miles, and the messages from Arlington were heard at times as far away as Honolulu, 4,000 miles. Many tests over long and short distances with wireless telephony have been carried out since then, but at the present moment there is no commercial wireless telephony system in operation, with the exception of a system recently installed between Avalon and California, a distance of about 30 miles. It is important to notice that wireless telephony is not restricted for work across oceans compared with wireless telegraphy as is the case with submarine telephony as compared with telegraphy, and this is a point which must be carefully borne in mind when considering the future possibilities of long-distance wireless telephony.

Point to Point.—The Post Office point to point stations are Stonehaven for medium range Continental communications, Caister for short range Continental, Northolt for long range Continental, and Oxford for working to Egypt. In addition, at the moment, Devizes is being used for a six hours daily service to Rome. Tests are just being commenced between Stonehaven and Berlin, the messages from Berlin are to be received on an aerial at the Central Telegraph Office and a signalling key at the Central Telegraph Office is to work the sending instruments at Stonehaven for the transmission of messages. By this means duplex working will be carried out. At Oxford, duplex working is being arranged for by having the operating station at Banbury and the power station at Leafield. As regards high-speed working, wireless signals can, of course, be received on a relay system (Wheatstone or Creed) or a dictaphone; the former is naturally preferable when practicable, but the advantage of the latter is that the signals can be read by ear off the dictaphone through a certain amount of interference, whereas with a relay system no use can be made of the great selective quality of the human ear for differentiating between notes of different pitch. In 1913 the Marconi Company carried out fairly satisfactory tests up to 140 words a minute on the dictaphone system, and up to the present they have used that system almost entirely. Recently the Army have opened a military service between Aldershot and Cologne at about 100 words a minute on a relay system. In the Berlin service the dictaphone will be used as a start at this end of the line, but it seems pretty certain that before long the dictaphone will give way everywhere to the relay. The Marconi Company have two high-power stations, Carnarvon and Clifden, both these work normally across the Atlantic at hand-speed duplex, and are often able to use high speed. In Germany, the Government have started a network of wireless stations, working at about 60 words a minute to supplement the telegraph system, and at the moment about 15 of these stations are working.

Wireless v. *Cables.*—As regards the relative cost of wireless and cables, there is no doubt that for short distances, up to say 500 miles, a wireless service is cheaper than a cable service when the latter does not require more than one wire. As the wires in the cable increase, however, so does the relative advantage of wireless decrease. Wireless for short distances is certainly very suitable for reduced services, as an overflow for cables, and for emergencies, but at present a great network of wireless stations in this country, working say to the Continent, corresponding to the present cable communication is not a practical proposition. For long distances, wireless certainly has the advantage, as in long-distance cables only one wire is used and the cable has also as a rule to cover a much greater distance than the crow-fly distance between the two points which it connects. For long distances the capital cost for cables is somewhere about four times as much, and the annual cost is slightly more than for wireless, so that it seems fair to contemplate that wireless rates for long distances will be less, say one-third less, than the present cable rates. In making any comparison it must be of course remembered that wireless, at present, cannot provide a service up to anything like the standard provided by cables.

Imperial Chain.—The Imperial Wireless Telegraphy Committee which reported last June, suggested that the Empire should be linked together by wireless stations placed at distances apart of about 2,000 miles. A route Oxford-Cairo-Nairobi-Windhuk, and a route England-Cairo-Poona-Singapore-Hong Kong-Port Darwin or Perth were proposed, as well as a connexion between England and Canada. It was suggested that thermionic tube transmission should be used at all stations except those now being constructed at Oxford and Cairo, that the stations should be planned by a small Commission, and that the erection should be carried out by the Post Office and corresponding Authorities in India and the Dominions. The initial annual loss on the scheme was estimated to be £100,000, of which £63,000 would fall on the Imperial Government, and it was thought that this loss would decrease until a profit was shown in 10 years' time. This assumption is in line with what has occurred on the Pacific Cable, which now pays well, but which was run at a big loss for the first 10 years. The capital cost of the scheme was estimated at about 1¼ million pounds and the annual cost about half a million. The Imperial Government would pay rather less than one million as capital cost and rather more than a quarter of a million in annual charges. This does not include the England-Canada link, which would cost about quarter of a million pounds with annual charges of about £90,000, and which would no doubt be a most valuable adjunct to the Imperial cable.

High-Power Stations.—The following is a list of the principal high-power stations in Europe:—

British Isles	...	Carnarvon.
		Clifden.
		Oxford (under construction).
France...	...	Bordeaux.
		Lyons.
		Nantes.
		Eiffel Tower.
		Sainte Assise (construction commenced last week).
Italy ...	...	Rome.
		Coltano.
Germany	...	Nauen.
		Hanover.
		Königs Wusterhausen.
Norway	...	Stavanger.
		Falkenberg (projected).
Russia	...	Petrograd.
		Moscow.
Holland	...	Kootwijk (under construction).
Serbia ...	...	Belgrade (projected).
Poland	...	Warsaw.

In the United States there are about a dozen high-power stations, and in Canada two. In China four are projected, and in Japan there are two, one of which was opened the day before yesterday.

At the present moment, considering our needs, we are distinctly behindhand with regard to high-power stations in the Empire, but it is not the first time that we have been a slow starter in a competition where we eventually took a prominent part, and we must just hope that history will do what is expected of it, and do that quickly.

TELEGRAPHIC MEMORABILIA.

"2,000 years' leave owing!" That was the announcement which caught the eye upon opening the pages of a South African Post Office Service periodical. The brief sentence was not invented by the fertile brain of an editor out for copy. It appeared as part of the finding of a Commission on the South African Post Office and which issued its report in December last. It was a well studied report by a Commission which sat for 200 days and examined 948 witnesses. One of its findings was that concentrated in the above four words, and relates to the accumulated leave due to the S.A. P.O. staff of all grades owing to the war.

Reference was last month made to the excellent contribution to the Benenden Games Fund by members of the C.T.O. The same staff have since subscribed the sum of £46 to the Civil Service National Lifeboat cause.

The word "Benenden" reminds one of the many thousands of men and women of the Post Office Service who have not yet become members of the "Sanatorium." As an insurance alone the tiny subscription offers unexampled advantages, and as an aid for less fortunate colleagues who may fall by the wayside it offers a facile way for anonymous helpfulness which cannot easily be denied.

On Jan 17 Mr. Louis Desous retired from active Telegraph Service in the Cable Room, C.T.O., on the completion of 40 years' connexion with telegraphy. Of French nationality, naturalised many years ago, he yielded to no man in his loyalty to British interests and had secured a particularly warm corner in the heart of the staff and supervision. Bright, cheerful and with a ready wit all his own, he quitted the floor of the T.S. Foreign amid the heartiest good wishes of all.

Before me stands a photographic group of four old T.S.-ites, three of whom have recently retired and whose modesty will not permit the mention of their names. The fourth is that of Mr. Alfred A. Parish, now superintendent of the W/T of the River Plate, Pacific and European Telegraph Co., who was recently home on furlough, but will have sailed for duty again by the time these lines are set up in type. Mr. Parish, it may be remembered, severed his connexion with T.S. somewhere towards the end of the eighties.

Writing of retirements one is struck by the frequent lingering thoughts backward in the direction of the retired one's former vocation. It is sometimes stated that once away from the telegraph office, all thoughts anent the sphere of the retired one's late occupation are banned and banished. Personal experience of the many of those who have left the Service does not coincide with that view. The writer rather finds an echo to the sentiment, expressed in a recent number of the *Bookman's Journal*, which drew upon Kipling for full expression of that power which lures men back to

"The things at which they used to earn their living
"Even when they were free."

Digitized by Google

Just as the sea-captain when—

> . . . "finished with the sea
> Still likes to feel it's there to use,
> If he should need it, as it used to be."

So also the telegrapher—deny it as we will. The pensioners, who came back to the Service during the war, themselves personified and proved this very principle.

Yes, love of the craft is still a fact, and you and I, gentle reader, have only to wait the time of our retirement to prove that :—

> "We've only one dear love to lose
> And when that's lost, it's there our hearts will be."

Mention of Mr. Garrood's retirement from the C.T.O. into the elysium of pensioned service was unfortunately crowded out together with several other items last issue. It is hoped that it is not too late to wish our well known friend a lengthy, happy enjoyment of his well-earned repose.

On Jan. 21 the London Office was placed in direct telegraphic communication with the town of Hanover, as a temporary expedient owing to breakdowns beyond that point. A very satisfactory service was given by the office just mentioned, an acknowledgment of which is readily placed on record in these columns.

The possibility of Baudot automatic transmission reliable information states, has become more and more promising, and it would be surprising to the writer if before long the system did not become an established fact. The French administration contemplates making a trial with an improvement on the old "Carpentier" *automatique* very shortly between Paris Bourse office and the London C.T.O. The new Baudot distributor, connexion box and pin-connexions which was sighted recently appears to be the last word in compact design.

It is mooted in quarters where information rarely fails to prove a true prophet that plans have been outlined for the production and publication of an Annual C.T.O. Magazine entirely produced by C.T.O. talent, both as regards its literary and artistic features. The obviously rich store upon which the organisers should be able to draw for the production of so desirable a work will at one and the same time make the task an easy and a difficult one. The price suggested is somewhere about 2*s.* 6*d.*, while provision is likely to be made for any accruing profits to be devoted to the C.T.O. or some kindred benevolent fund.

By the way, certain Russian authorities in this country who have made full use of cable facilities offered by the British Government, with a kindly feeling and thought for followers of our craft recently presented the sum of £30 for the benefit of the C.T.O. staff. This sum has accordingly been handed over to one or two of the many useful organisations for the alleviation of special distress or need associated either with the C.T.O. itself or with the Post Office Service generally.

Some of our readers have been surprised that Wheatstone transmission and reception should be possible with wireless telegraphy. There is, however, nothing very remarkable in this possibility as whether hand or machine be used the principle of the signals remains unchanged. As can be well imagined by those conversant with some of the developments of "wireless" the Creed printing system can easily be adapted in place of Wheatstone reception. Hughes has been proved practicable and there does not appear to be any serious obstacle to many types of high-speed telegraphy being employed. Indeed, Siemens automatic transmission by means of wireless is already a *fait accompli* between Berlin and Leipzig. The Baudot, Murray, and Western Electric systems should therefore lend themselves equally well to the new medium. "Atmospherics" and "jamming" have of course not yet been overcome but undoubtedly notable advances are being rapidly made. The clear-cut and well defined nature of the signals between Cologne and our own metropolitan centre, which signals the writer has had the opportunity of closely examining, gives every promise of excellent results if applied to machine telegraphy printing systems. The absence of capacity effects produces a practically distortionless tape during periods when "atmospherics" are at or near zero power. It would need no great shrewdness to guess that a Creed trial between London and the Rhine district will prove a natural sequel. It may be interesting to note that one of the first if not *the* first to adapt Wheatstone apparatus to wireless needs was the honoured name of Creed, under patent 19,125 Creed F.G., and Creed, Bille & Co., Aug. 22, 1913. In this provisional patent, specifications 1061/02, 5490/05, 23,834/08 and 3853/13 are also referred to. For this latter information together with certain sketches of the fluid-pressure motor utilised myself and our readers are once more indebted to one of our many younger men who are whole-heartedly interested in the most modern phase of our craft. Wheatstone slip of the most perfect type was recently received, practically at the door of the C.T.O. London, by means of "wireless" from one of the Rhine cities direct at a rate, during the most favourable atmospheric period of the twenty-four, of no less than 150 words per minute. Readers will be interested to know that Post Office civil telegraphists were at each terminal office. It is hoped that shortly, if not in the present number, then later in these pages, some interesting details may be published of these epoch-making experiments. One item it is not possible to keep back. The Wheatstone receiver used at the German end was one which was recovered by the British Military from the waters of the Rhine after a month or two of immersion!

The experiment reminds one of the words of Sir William Slingo at a meeting held in the hall of the Electrical Engineers' Institute when speaking of modern machine telegraphy, he said: "Morse will always be needed in telegraphy."

The developments in connexion with wireless become more and more amazing and yet there seems no need for the closing down of underground and submarine cable factories up to the present.

It is at present difficult to obtain reliable particulars of the capital costs and upkeep charges of long-distance wireless installations. Maybe one day the Accountant-General's Department will be able to reveal to us, when time and experience have supplied sufficient data, the capital cost, the maintenance charges and the relative life of wireless installations for a given distance as compared with submarine and underground cables, working over the same or similar distances. This, together with other interesting matter covering the reliability at all seasons and at all times of the day of the two systems should determine the relative suitability of one or the other for point to point communication *unlimited* in number. In this connexion *selectivity* may well be expected to play an important part as regards telegraphy without wires.

It was a matter of very earnest discussion at the International Conference for the Amelioration of postal, railway, telegraphic and telephonic communications in July last at Paris that Radio-telegraphy could not be maintained absolutely as secret as that by means of wires especially as modern developments had rendered it possible for anyone with the necessary knowledge to receive with antennae, signals transmitted by stations as far away as 8 to 10,000 kilometres. High-speed telegraphy having become an accomplished fact in connexion with "wireless," fears on this point may be promptly dismissed for ordinary commercial purposes. For naval and military aims the increased sensitiveness of modern receiving apparatus, to a degree at one time inconceivable has added a serious disadvantage as a counterbalance to the undoubted utility of this form of communication. The whole matter opens up a field of the most debatable and interesting ground for enquiry, investigation, the most careful research and the most ingenious of inventions.

Lieut.-Colonel C. G. G. Crawley's paper read before the T. and T. Society of London fortunately appears in the present number of our JOURNAL and gives some specially interesting views, information and side-lights on wireless developments. The Belgrade installation mentioned is now actually functioning and daily assists the London office with a certain amount of traffic destined for Serbia and Yugo-Slavia. So far as Belgrade is concerned, it only provides for Anglo-Serbian traffic during a very small portion of the twenty-four hours, the Serbian capital and the British high-power station both being occupied with traffic in other and various European directions during the remaining hours of the day. This arrangement is an awkward one and presents objectionable elements as regards availability.

J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

Engineering Faults.—When the present district was formed immediately after the Transfer, a fault scheme was designed and introduced, providing for a daily record of engineering faults to be kept at the exchanges. Under this scheme separate totals for faults at exchanges, subscribers' stations, and on the lines, are submitted weekly to the Superintending Engineer's office, where they are carefully scrutinised and tabulated.

A monthly summary of the figures for the exchanges in each of the sections is prepared, and circulated to the members of the staff responsible for the maintenance. By publishing comparative results in this way an effective stimulus is produced towards improved results. The following figures for the past nine years show the steady progress which has been made in the direction of higher efficiency :—

Year.	Faults per station per annum.	Remarks.
1912	3.52	
1913	3.52	
1914	2.31	
1915	1.77	
1916	1.81	Great snowstorm March 1916.
1917	1.55	
1918	1.39	Stagnation in trade.
1919	1.54	
1920	1.51	

The improvement during the last nine years continues, and it is hoped that before very long the ideal standard of an average of one fault per station per annum will have been reached throughout the district. At several exchanges this high-water mark has already been reached.

Institution Meeting: Thermionic Valves for Wireless Purposes.—A few years ago a writer in a technical journal was lamenting the absence of literary skill on the part of inventors and investigators who attempted to put into writing the results of their work. There can be no doubt that with certain exceptions the criticism was justified, and it is a matter for regret that such should be the case, since few things in life are so full of romance as the discovery of natural laws and their application to the needs of man.

Digitized by Google

There is no doubt that many patient and skilful investigators have spent their whole lives in endeavouring to solve some of the problems that have baffled mankind, but have passed away without leaving on record the result of their discoveries. Probably they had no taste or aptitude for literary work, and considered the preparation of a scientific paper or treatise a task quite beyond their powers. Others have made the attempt but have been so singularly unsuccessful in describing their discoveries that their work has passed almost unnoticed.

In some cases a man with journalistic talents and some scientific knowledge has unearthed a paper which otherwise would have been condemned to obscurity and, by writing upon the subject, has drawn attention to the importance of the inventor's work.

It is refreshing, therefore, to record that at a meeting of the I.P.O.E.E. at the Society of Arts on Feb. 14, a paper of high literary merit was read by Mr. F. W. Davey, the subject being "The History of the Development of Thermionic Valves for Wireless Purposes." To those who were not present the title may not sound very alluring, but all those who were privileged to be present will testify that they have rarely listened to a paper on any subject which more engrossed the attention of an audience.

So much has been written on the subject of Thermionic Valves and the tremendous revolution wrought by them in the realms of Telegraphy and Telephony that the need for another paper may not have been widely felt. Mr. Davey, however, invested the subject with a new interest as he traced the path from the first accidental discovery to the present highly developed application of the valve to wireless working.

The use of the electric light bulb for illuminating purposes is now so common that the ordinary user looks upon it as nothing but a convenient means of obtaining light. To the scientist, however, this bulb has great potentialities. The investigation of what takes place in the apparently empty space between the hot filament and the bulb has led to discoveries which have widely extended the scope of wireless working and has made it possible to speak over great lengths of small gauge underground wire.

By suitable modifications this electric light bulb, which looks so innocent and commonplace, can be used as a generating unit for heterodyne working. It provides the easiest and most efficient method of continuous wave reception ; it can be made to serve as a magnifying and rectifying device, and it has made fast speed wireless communication possible.

Mr. Davey prophesied that by the use of this device it would be possible in the near future to have a commercial trans-Atlantic telephone service and that type-printing telegraphs will, at no distant date, be operated by wireless signals. He pointed out, however, that there are very real difficulties yet to be overcome, but, as the history of past achievements was unfolded, no one could doubt that there was every warrant for the speaker's optimism.

A responsive note was struck in the breasts of all present when Mr. Davey pleaded in his closing sentences that a greater measure of recognition should be given to the value of the pure research and experimental work carried out in the Department. As we have an enthusiastic Engineer-in-Chief and a sympathetic Secretary, it is confidently expected that the recognition will be accorded and the fullest facilities provided for carrying on this important work.

An interesting feature of the discussion which followed was the reading by the secretary of a letter from Professor Fleming who had been invited to be present, but who was unable to do so owing to a previous engagement. Prof. Fleming's main criticism of Mr. Davey's paper was that sufficient credit had not been given to the research work carried out by himself on the Edison effect, from 1884 onwards, or to his investigations which resulted in the invention of the two and three electrode valves.

Other speakers, however, realised the difficulty of compressing a history of so many years of work into the compass of a short paper and paid a well-deserved tribute to the author's clear summary he had given of the thermionic valve. Among those who took part in the discussion were Mr. E. H. Shaughnessy, O.B.E., of the Wireless Section, Engineer-in-Chief's Office, Mr. J. E. Taylor, Superintending Engineer, South Midland District and Mr. Burrows, of the Wireless Traffic Section of the Secretary's Office. The latter hoped it would be possible to supply copies of Mr. Davey's valuable paper to every wireless station in the country, where they would be of considerable utility.

Memories.—The Office of Works has in hand an extension of the North Telephone Exchange premises. The enlargement is not being made to enable the switchboard to be extended, but to provide much needed additional accommodation for the staff. It is interesting to recall that this building was once a meeting place of a religious sect known as the Sandemanians and that Faraday, who was an elder of the Church, used at times to preach there. This fact is recorded on a tablet affixed to the switchboard wall. The tablet was unveiled on Nov. 24, 1906 by Lord Kelvin. Lord Kelvin's interest in the telephone began in 1876 when he was present at a demonstration given by Graham Bell of apparatus enabling the transmission of spoken words by electric currents, through a telegraph wire. Lord Kelvin prophesied at the time that "with some more advanced plans and more powerful apparatus we may confidently expect that Mr. Bell will give us the means of making voice and spoken words audible through the electric wire to an ear hundreds of miles distant." Both Mr. Bell and Lord Kelvin lived to see the fulfilment of this prophesy. Members of the ex-N.T. Company will always treasure the memory of having been present at a staff dinner in 1906 at which Lord Kelvin as a guest made a vigorous speech.

Perhaps the most widely quoted saying of the great scientist and the one which appeals most to engineers is the following :—

> "I often say that when you can measure what you are speaking about, and express it in numbers, you know something about it, but when you cannot measure it, when you cannot express it in numbers, your knowledge is of a meagre and unsatisfactory kind."

Exchange Extensions.—The extension of the Hornsey and Victoria Exchanges which were forecasted in the January issue have been completed. and in addition extensions at Barnet, East Ham and Avenue have been carried out. Extensions and alterations are in progress at Ealing, East, Enfield, Finchley, Gerrard, Hampstead, Hop, Kensington, Lee Green, New Cross, North, Park, Streatham, Tottenham, Walthamstow, Willesden, and Wanstead. The new exchange at Harrow is very near completion and will, it is hoped, be handed over for working by the time this issue is in the readers' hands. The first of the relief exchanges to be opened—Langham—will also be ready for opening early in March. The other relief exchanges—Chancery, Minories, and Grosvenor—are well advanced, as are also the new exchanges in course of construction at Clerkenwell and Toll.

A contract has been let for a new exchange at Barnet, but, owing to the large amount of work in the hands of the Contractors, operations are not likely to be commenced for some months.

The new buildings for the accommodation of exchanges at Stratford, Monument and Holborn are proceeding apace.

The preliminary arrangements in connexion with the Panel Automatic Exchange at Blackfriars are making good progress, and much midnight oil is being burned by some of the engineers closely concerned.

Wireless Installations.—The amount of interest taken in wireless communications nowaday is very considerable, as is evidenced by the number of applications received by the Postmaster-General for licences, both for reception and transmission.

The present number of licences in the London District is close on 1,000, and applications are being received at the rate of about 15 per week. The installation and use of wireless apparatus without a licence is prohibited under the terms of the Wireless Telegraphy Act of 1904. The possession of wireless apparatus without a licence is prohibited under Section 22 of the Defence of the Realm Regulations. This section is still operative.

The majority of licences issued are in respect of receiving stations. Apart from personal guarantees the conditions are that the extreme height of the aerial above ground shall not exceed 100 ft., and the total length of wire including the lead in shall not exceed 100 ft., for a single wire aerial or 140 ft. of wire where two or more wires are used, *e.g.*, total length for a two-wire aerial would be 70 ft. A receiving licence costs 10*s.* per annum. A thermionic valve may not be used without the written authority of the Post Office authorities. Transmitting licences, which cost 20*s.* per annum, are only issued to persons who can give definite proof of research work of commercial public or scientific utility. Before a licence is granted the names of not more than 5 persons with receiving stations, willing to co-operate with the would-be sender must be submitted with evidence of their consent. The power of sending stations is limited to 10 watts, or less, and the period of use is restricted.

The specified wave lengths are generally 180 metres for spark transmission, and 1,000 metres for fixed transmission. Permits from the Postmaster-General are necessary for the sale of wireless telegraph apparatus under the Defence of the Realm Regulations, and sales may only be effected with persons in possession of an operation licence.

The present instruction is that every wireless station is to be inspected once per annum and this work, with certain exceptions, falls upon the District Engineering Staff. In order that the officers selected for this duty shall not be at a disadvantage when making inspections arrangements are being made to give them a course of instruction at the District Apparatus School, at Denman Street, which will shortly include a wireless section. An aerial is being erected for reception. Transmission will be limited to practice with frame aerials within the schools.

Quite a number of officers of the department are already enthusiastic amateurs, and some have joined one of the numerous wireless societies which exist for the purpose of fostering interest in this subject.

Classes in Wireless Telegraphy are now held at most of the Polytechnics and Technical Colleges.

Abbreviations.—The tendency of the time is to make use of abbreviations both in speech and writing. Under certain circumstances abbreviations are permissible and advantageous, for example, the use of F.O.K. to indicate briefly that a circuit is found to be free from fault, represents a considerable saving in human effort when the enormous number of times it has to be employed is taken into account.

The clipping of words in conversation however, is indefensible. Such as expression as—under the circs—is an offence to the ear. It is regrettable that it is becoming a habit with the public to shorten the word telephone to 'phone. It is still more regrettable that some who are engaged in the telephone business are addicted to this vice. It is to be hoped that now attention has been drawn to the matter the offenders will mend their ways and set a good example to the public at large.

Special Constabulary.—A Bohemian concert, organised by the Southern (Engineering) Group of the Post Office Special Constabulary, was held at St. Matthew's Hall, Brixton, on Tuesday, Jan. 25.

A splendid programme was presented to a large and appreciative audience and the entertainment committee has to be congratulated on its success.

Digitized by Google

Among the artistes were ladies of the London Telephone Service and members of the Engineering Department. The "turns" included songs at the piano, an exhibition of ventriloquism, concertina duets, and also the usual ballad and humorous songs, all of the items being well applauded and proving very enjoyable.

At the interval, during which refreshments were provided, the Commandant of the Post Office Division, who was present, made a short speech dealing with the growth of the Post Office Special Constabulary.

It was afterwards announced that it is the intention to hold a series of social functions during the winter season, the next event will probably take the form of a whist drive and dance.

Denman Chess Club.—On Jan. 9, Mr. J. Kniager, of the Woolwich Chess Club, gave a simultaneous display against 12 members. Playing brilliant chess he won all 12 games in less than two hours. It is hoped to arrange a second visit.

A return match with the London Telephone Service was played on Feb. 9 and resulted in a win for the Club by 7 games to 4.

LONDON TELEPHONE SERVICE NOTES.

THE Annual General Meeting in connexion with the Telephone Staff Hospital Collections took place at G.P.O. South on Wednesday, Feb. 2. The meeting was well attended, and Mr. Preston, the Chairman of the Committee, presided.

The report for the year 1920 was a very satisfactory one, the collections amounting to £1,451 4*s.* 2*d.*, which is £228 in excess of the previous year. The staffs of the Controller's Office, the Exchanges, the Contract Branch, the Engineering Department, and the Electrophone Department, all contributed towards this result. 841 benefits by way of letters were issued to members of the staff during the year.

Mr. Preston in proposing the adoption of the report, complimented the staff on their efforts in aid of the Hospitals, and expressed the hope that during the ensuing year it might be possible for the collections to reach the sum of £2,000. Miss Heap and Mr. Stirling were amongst the speakers, also Mr. Inman, the Secretary of the Hospital Saturday Fund, who spoke of the urgent need of our hospitals, and the good work done by the Telephone Staff.

Mr. Preston was unanimously re-elected Chairman for the ensuing year. Mr. J. Leslie was re-elected Hon. Treasurer, and the Misses A. Reekie and H. Wormald, Hon. Secretaries.

* * * *

We hear that Mr. G. W. J. Praat who was Exchange Manager, Croydon, from 1910 to 1913 has been appointed Assistant Postmaster-General, Ceylon. After leaving the London Telephone Service he went to the Provinces as an Assistant Traffic Superintendent and in 1916 accepted the post of Superintendent of Telephones and Telegraphs in Ceylon. He has the congratulations of his former colleagues.

* * * *

Unfortunately, the compliments received by the Telephone Service do not achieve such prominence as the complaints. Here is a recent one, however :—

The Controller,
London Telephone Service.

Sir,—I enclose 10*s.* as a deposit for Trunk Calls. At the same time I desire to pay a very warm tribute to the Supervisors and operators of the ————Exchange for the excellent service they are rendering. There is certainly a vast improvement in the service, and as we are only too ready to grumble when the service is bad it is only right to appreciate when the service is good.

Please convey my thanks to the Exchange staff.

Yours faithfully,

* * * *

London Telephonists' Society.—The sixth meeting of this Society this session was held on Wednesday, Feb. 2, when two of the successful competition papers were read.

The subject of this year's competition was "Suggestions towards the improvement of the service." Some express the view that an invitation to compete should have been extended to newspaper "experts." Strangely enough, the comments of those experts found no place in the competitors' papers and there is no reason to believe that the newspapers would have secured a prize.

The Papers' Committee found the task of singling out one paper as the best beyond their power and they judged three to be of equal merit, viz., those submitted by Miss D. M. H. Bott of Park Exchange, Miss J. R. Dalley of Western Exchange, and Miss J. M. McMillan of the Headquarters' Traffic Branch.

Miss Bott and Miss McMillan read their papers at this meeting to the evident enjoyment of those present.

Miss Bott's paper was full of suggestions on points of detail gleaned during some years of experience in telephone switchrooms and was delivered in a refreshing and vigorous style.

Miss McMillan's paper was an excellent foil to the paper that went before and dealt with the subject on the broader lines of principle. The writer's lyrical touch was once more enjoyed.

The last meeting of the session will be held on March 2 at the usual venue. Miss Dalley's paper will be read and an Elocution Competition will be decided.

* * * *

City Exchange.—A peep into the stately Hall of the Stationers' Company on the evening of Feb. 12 would have revealed a scene brim full of colour and sparkling with the delight and enthusiasm of the City staff and their friends as they revelled in the dance. A more enjoyable evening of the kind they have not held and so pressing have been the requests for a repetition that arrangements are in hand to hold a "flannel" dance on April 23.

Clerkenwell Exchange.—On Feb. 12, 120 children from Wenlock Street School were entertained at the Leysian Mission Hall by the staff of the Clerkenwell Exchange. While tea was in progress Mr. Delahaye gave an impersonation of one of the children's favourite film actors "Charlie Chaplin," which caused a great deal of fun, and later in the evening a few little friends of the Misses Bloodworth and Dawkins delighted the children with songs and dances. This was followed by the old-fashioned but very popular item, a Punch and Judy show. The singing of choruses and the playing of games occupied the remainder of the evening and finally on leaving each child received two parcels and two oranges.

In these days when adverse criticism is so prominent, it is gratifying to hear a remark passed by the Headmaster of the school to the effect that he had been told by one of his colleagues that *anything undertaken by the Telephone staff was sure to be a success.* The children's happy faces certainly justified the remark on this occasion.

East Ham Exchange.—The staff entertained 200 children of the unemployed of the district to tea on Saturday, Feb. 12. The tea was followed by an entertainment which included Bert Mino's Marionettes, for which item thanks are due to "Broadway." Competitions were arranged and prizes given; the sweet tooth was not forgotten and fruit and cakes formed a parting gift. The evident enjoyment of the youngsters was abundant satisfaction for all who contributed to the success of the occasion.

Finchley Exchange.—The annual tea party given by the Traffic and Engineering Staffs of the Finchley Exchange to the children of the Wright-Kingsford Home, Finchley, was held on Saturday, Jan. 22. After tea a Christmas tree afforded great delight to each small recipient of a gift, which included sweets and bon-bons. The remainder of the evening was spent in games and competitions enjoyed by both the entertainers and the entertained.

Gerrard Exchange.—On Jan. 29, the staff entertained once again the soldiers at the Queen's Hospital, Sidcup, to a tea, whist-drive and dance. Great appreciation was shown by the patients and members of the Hospital staff who thanked the Committee again and again for organising entertainments on such a generous scale. During 1920 the Gerrard staff contributed over £100 towards these functions, and it is the general opinion that the money could not have been put to a better object.

Kensington Exchange.—From the proceeds of a dance held on Jan. 14, the staff of the Kensington Exchange have sent a donation of £10 to the St. Dunstan's Blinded Soldiers and Sailors' Fund.

Stratford Exchange evidently has a very energetic though comparatively small staff. They set out to raise a sum for the War Seals Foundation by means of a concert and the result was that the receipts totalled £54 10*s.* 0*d.* or an average exceeding £2 per head of the staff. The comment "highly successful" is hardly adequate.

Streatham Exchange.—A very pleasant and jolly evening was spent by the staff at a dance which was held at Madeira Hall, Streatham, on Jan. 27. The function was well attended by members of the staff and their friends. Popular music rendered by the orchestra added greatly to the full enjoyment of the evening. It is a great satisfaction to the staff to know that there is a balance of over £10 from the sale of tickets, which it has been decided to forward to St. Dunstan's Home.

Paddington Exchange.—On Feb. 12 a very successful entertainment and tea was provided for over 300 poor children at the L.C.C. School, Cosway

Digitized by Google

Street, Paddington, by the staff of the Paddington Exchange. The tables presented a very animated appearance when the children sat down. Each child had a bon-bon and on every plate was a small jelly. After Grace, the children fell to and soon the air was resounding with the cracking of bon-bons. Caps of bright hues were soon in evidence on the children's heads, and with startling rapidity bread and butter, cakes and jellies disappeared. The hall was cleared for the entertainment and strains of music preceded the arrival of ten pretty Pierrettes, who danced on to the stage singing their opening chorus. For the next hour and a half the fun was fast and furious, the children joining heartily in singing the choruses. As the little heads began to nod the entertainment was brought to a close, but the children were not too tired to give three rousing cheers for their entertainers. On passing out each was given a bag of fruit and a bright penny. Several letters were received subsequently from the children saying how much they had enjoyed the party.

Our very best thanks are due to all who assisted in any way to make the afternoon such a complete success, for as the Headmistress says in her letter, "it will be a bright spot in their lives for a long time to come." This is our reward.

Photo by Messrs. Barratt's Photo Press, Ltd.

HOLBORN EXCHANGE NOTES.

A real live Father Christmas ! The spirit of Christmas found a material form on Jan. 26 when one hundred and fifty of the poorest children in the vicinity of King's Cross were invited by the Staff of the Holborn Telephone Exchange to a Tea and Christmas Party. The first thing they saw as they gave up their tickets and entered the beautifully decorated schoolroom was Father Christmas himself, who welcomed them with a handshake. You should have seen the faces of those little urchins as they beheld him ! When they had done justice to their palates and pockets with the good things which had been provided, Father Christmas told them that all the people who worked in the Holborn Telephone Exchange had given or collected over £70 in order to give expression to their Christmas sentiments of goodwill and charity to some poor children and that they were the lucky children. Conjuring, Punch and Judy and a Fairies'Concert Party were the principal items of the programme which followed the tea. Mr. Marks also directed the children in singing some well-known songs in which they justified their little "King's Cross Linnets." As they took their departure each one was given a suitable present, an article of clothing and an orange. The Minister of the Church, who very kindly lent the schoolroom, proposed a vote of thanks to the Holborn Telephone Exchange for giving his " terribles " such a treat, and Mr. Ballard suitably responded.

Among the changes in the London Telephone Service, in the first eek of the New Year, the transfer of Miss Butler to London Wall Exchange was an event of significance, not only to Miss Butler herself, but to the staff at Holborn where she has been stationed since 1914. The esteem in which she was held by all the staff, and an appreciation of the manner in which she has filled the rôle of Chief Supervisor of an important Exchange during the difficult years of the War were expressed by Mr. Ballard when, on behalf of the Supervisors and Staff, he presented her with a diamond ring. Miss Butler had, he said, attached herself to all the staff, and he was sure that the regret which he knew she felt at parting was shared by all with whom she had been associated. They one and all wished her equally happy associations and even greater prosperity in her future spheres. Miss Butler suitably responded.

DISCIPLINE: IS IT NECESSARY ?

BY AN ASSISTANT SUPERVISOR.

DISCIPLINE—awful word—how we all kick against it ! Yet someone has said that we are only really happy when disciplined. Apparently a contradiction, for we all desire happiness.

Apart from the question of law and order, which must always be, there are some interesting points which could have more light. Discipline makes independence. There is no doubt of that, and, if we always act according to instructions, we naturally get a free and happy independence—an independence that no one can touch.

I often remind telephonists with whom I work that if they carry out instructions, they make themselves almost independent of supervisors We should then all be happy, and, of course, there would be less work to do. What a pleasing prospect ! Moreover, independence is the spirit of the age, so we should be quite up to date in that way.

Again, in working according to authority—a law of nature—no one is dependent on individual caprice. I shall not attempt to calculate the number of instructions that have been issued, but we know and understand all the governing principles. Both in our own world and in the world outside, the disciplined individual is easily recognised; in fact, he or she is the only comfortable person with whom to work or live. Undisciplined people usually claim to be temperamental—poor dears !

Consider an actress; she says the same words day after day as we do, and her success depends on the impression she creates by her manner of delivery. Our work is alive—it is teeming with interest, and we must " act " and " act " with our voices. A film actress is seen but not heard; a telephonist is heard but not seen.

We are expected to convey by " expression " all that subscribers must understand, and they do understand. How often we hear: " It was not what he said, but how he said it." Speech is only right and pleasing when distinct, and this depends on the mobility of the lips or the flexibility of the muscles of the lips. If this were given full play we should not hear of voice strain so often. In fact, to speak expressively, which is most fascinating, all the muscles of the face up to the eyes should be in play.

Now consider the daily effect on the London public of 5,000 well-produced and modulated voices helping to smooth the general friction of the work-a-day world. The modern girl can be congratulated on keeping all their prickles out of sight; in fact, there are not many left in these days.

It is not so long ago that we were very prone to take personally everything those around did or said. This is indeed a much more sensible age, in spite of all that has been said of the modern girl. During the day all sorts of things crop up, and we should take each as it comes as part of our work, without going off the deep end !

We have realised our mistakes and learned that life is impossible unless we give and take, or carry out team work all the time. This surely is the *esprit de corps*, not that kind of brotherhood business which consists mainly of shaking hands in an enervating atmosphere.

Humour is another quality—it is the great antiseptic, so we smile when we feel inclined. It may sound unbusinesslike—I don't know—but we smile if it feels right. It is not always necessary to have the capable business woman written all over one to be successful, and that just proves in another way that our work developes our personality.

It is all so interesting dealing with human beings like ourselves. Fancy living only among books and papers !

Stevenson says something to the effect that books are anaemic things compared with real life. The subscribers we talk with are the same as those remarkable people we read of in novels. We all have crises at some period of our life, which would sound thrilling in a book, only in a book the uneventful years are left out.

We need imagination; we should always endeavour to see things from the subscribers' point of view, and then lead on to our own: where the two meet is the correct stopping place. And we must meet even if we have to build a bridge. If we are right, and we always are, take things easily; some people are in too much of a hurry to be right.

We must not get discouraged when it is thought that there is no progress. Anything worth doing is not as a rule done quickly. Conditions are improving, but it appears, oh ! so slowly, at times. The country parson once said of his Church, " we do not jerry-build, neither do we seek to deceive by building the back parts shabbily."

When in doubt as to any course of action, we should do what we think to be right (everything is either right or wrong), but at any rate we do something —we act. So that the accusation of being wanting in initiative cannot be charged against us.

All the training or discipline we receive in the Service is an asset which should last our lifetime. I think a good telephonist is a charming person to meet; she has my sincerest admiration. And I think I am right in saying

Digitized by Google

that she is popular everywhere. I know this is true of those who went to France.

I wonder if we all realise how much our first years in the Service mean to us. It is then our reputation is made, and once made it always sticks. We all love a reputation, whether it is that of Ellen Terry or Beecham's pills! And in the world of telephones the telephonist must take the lead—it is her work; the public will follow.

It has been contended that a woman's reasoning powers are sometimes missing. This, of course, is pure heresy, but perhaps the difference is just this—a man thinks step by step 2+2+2=6 and it is so. A woman sees that 2+2+2 looks like 6, and she also is right, but if she be wise she will prove it before saying so.

I would recommend telephone operating to the pessimist. We get a complaint full of the most serious accusations; we investigate, invariably to find that nothing is as bad as it is painted, which proves that pessimists, who mostly judge by appearances, are wrong.

The enforcement of punctuality is a pet grievance with many of us. Yet we must admit that this is necessary when we relieve or are relieved by others. And we never have to suffer at the other end of the day. We are free to make our arrangements undisturbed, and we have thus freedom because the rules of punctuality are so strictly enforced. Discipline again!

In these ways and in many others, we help to make the new world by the effects of our work. Is it a good one? It must be; there is no excuse for indifference in these exciting times.

"Every day a fresh beginning,
Every morn is the world made new."

E. PYNE.

PRESENTATION TO MR. C. L. PARSONS.

An enjoyable New Year Social gathering of the Brighton Telephone staff at the Pavilion Creamery, on Thursday evening, was the occasion of an interesting presentation to Mr. C. L. Parsons, Chief Clerk of Telephones, who has just retired after 33 years' service. The Staff's gift was a gold watch suitably inscribed, together with an umbrella for Mrs. Parsons.

Mr. P F. Currall, District Manager, in making the presentation on behalf of the staff, spoke in appreciative terms of Mr. Parsons' long and efficient service. The whole of Mr. Parsons' Telephone career had been spent in the Brighton District, and during his association with the service it had grown from exceedingly small proportions until the telephones in the District now numbered over 12,000. He desired to record his appreciation of Mr. Parsons' business ability, tact and geniality in dealing with the general conduct of the Telephone Service, and he took this opportunity of thanking him officially for the loyal support and untiring work which he had always placed at the disposal of the Department. He was sure he was voicing the feelings of the staff when he said that it would not be possible to find a more loyal, kindly and considerate chief, and in bidding Mr. Parsons an official farewell he hoped that both he and his wife would be spared for many years to enjoy their well earned retirement.

Mr. Currall's remarks, which were cordially endorsed by Mr. F. W. George, Contract Manager, and Mr. A. Lumsden, Traffic Superintendent, were received with acclamation by the staff.

Mr. Parsons, who spoke with considerable feeling, said he was unable to sufficiently thank Mr. Currall and the staff for their kindly appreciation in presenting him with such a handsome memento of a long and happy association with the Telephone Service. He had always endeavoured to carry out his duties by combining business efficiency with consideration for the welfare of the staff, holding the view that a contented staff was usually an efficient one. He was proud to know that on his retirement he was taking with him the kindliest thoughts and best wishes of the whole of the staff.

LLANDUDNO AND DISTRICT TELEPHONE STAFF SOCIAL.

The engineers and telephonists of the above district held a very successful social evening on Jan. 12 at Payne's Café, Llandudno.

The Postmaster, supervising officers and staff of the Head Post Office were the guests of the evening, and members of the staff and friends attended from Colwyn Bay, Conway, Old Colwyn, Deganny, Llanrwst, Penmaenmawr and Bangor.

Mr. J. A. Robinson, Inspector, occupied the chair, and in a few well chosen words welcomed the guests, the Postmaster, Mr. W. W. Young, responding suitably.

Mr. J. Parsons (Engineers) and Miss Kennerley (Travelling Supervisor) acted as host and hostess, while the M.C.'s were Miss Rich (Telephones) and Mr. E. Williams (Engineers), assisted by Miss Gwen Jones (Telephones) and Mr. Willett (Engineers).

An attractive programme of games, competitions and musical items had been arranged and the fun was fast and furious from 7.30 p.m. until after midnight. Full justice was done to the excellent supper provided and all agreed that a most enjoyable evening had been spent.

CORRESPONDENCE.

CAUSE AND EFFECT.

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

SIR,—In your article under this heading in your current issue, you say "The cost of its goods to the public is artificially inflated by the newspaper ramp." This is a misconception, as a matter of fact, the cost of goods is reduced by using the Press as a medium for advertising. Sales costs have always been a heavy addition to the manufacturing costs as travellers and travelling expenses must be paid, and the manufacturer is naturally obliged to take this into consideration before arriving at the price to be charged to the wholesale trade, and the wholesale traders are equally obliged to do the same before fixing their price to the retail trade.

The public appealed to direct and made acquainted with the merits of the article through Press advertisements, now ask the retailers for the goods advertised. The saving in selling costs brought about by Press advertising is enormous, as I will endeavour to show in this letter.

I do not know the evening paper which charged the price of £1,200 for one insertion of an advertisement, certainly no evening paper has such a rate on its published scale, but that is by the way.

No article can be sold without publicity in one form or another. The primary method is by travellers calling upon retailers, and the salesman in the retail establishment recommending to calling customers. The secondary method is by circularising the possible consumers. The third method is to inform the public by means of advertisements in the Press (bill-posting is merely auxiliary).

May I set forth the comparative costs of these methods, in the reverse order in which they are given above.

PRESS ADVERTISING.

A full page advertisement in a daily paper, say the *Daily Mail*, with a circulation of *over* a million. The current scale rate for front page is £1,000, or an average cost per thousand of £1. (You may take it there are many readers of the paper who are not the original purchaser, but that is all to the good).

CIRCULARISING.	£	s.	d.
One million stamps at ½d.	2,083	0	0
Printing one million circulars at 10s. ...	500	0	0
*Envelopes, one million at 5s.	250	0	0
*Addressing at 5s.	250	0	0
	£3,083	0	0

* These are below present prices.

PERSONAL CALLS BY CANVASSERS.

To visit one million in one day, say at the outside 50 calls per man, would demand an army of 20,000 men. These at the lowest estimated cost for wages and travelling expenses could not be less than 15s. per man for the day. Total £15,000. We do not think any reasonable man would advocate a reversion to the old-fashioned method of personal canvas after comparing these figures.

SELLS, LTD.

[We think Messrs. Sells takes our contributor's quip rather seriously. We fully appreciate the valuable publicity of newspaper advertisement and agree with Messrs. Sells that it is probably a very cheap and effective form of canvassing, but we think they miss our contributor's point, viz., that the Press which is attacking the new telephone rates so vigorously and so unanimously, raise their own charges far more promptly and in a far greater ratio. The consumer does in fact pay the extra cost of advertising, although he may gain from newspaper publicity when that method of bringing goods to the public notice is adopted in place of a more expensive method. The telephone tariff was designed on the commercial plan of asking the consumer to pay for the quantity he consumes, just as he would pay more for the whole front page of the *Daily Mail* than for an inch of it.—ED., "*T. & T.J.*"]

NORWICH TELEPHONE DISTRICT NOTES.

The second annual dinner of the District Manager's staff was held at the Royal Hotel, Norwich, on Jan. 6, 1921. The chair was taken by Mr. C. F. Ashby, District Manager, and the visitors present were Mr. F. C. Luke, Surveyor of the Eastern District, Col. Treble, C.M.G., Postmaster of Norwich, and Mr. T. Lakey, Sectional Engineer, Norwich. The dinner was followed by a concert and the whole of the proceedings were of an exceedingly pleasant nature.

On Thursday evening, Dec. 30, the District Staff, Post Office Telephones, Norwich, met to pay tribute to the memory of Lieut. W. H. Parish, one of their colleagues who fell in the Great War. The memorial took the form of an enlarged portrait suitably inscribed and was unveiled by Mr. C. F. Ashby, the District Manager. The dedication service was conducted by the Rev. A. R. Barnes, who in a few well chosen words, emphasised the great spirit of brotherhood and self-sacrifice.

TELEGRAPH SUPERVISING OFFICERS' CONFERENCE.

THE third annual Conference of Telegraph Supervising Officers was held at the Secretary's Office, G.P.O. North, from Feb. 22 to Feb. 25, inclusive. The chair was occupied by Mr. R. A. Dalzell, C.B.E., Chief Inspector of Telegraph and Telephone Traffic, and the following Telegraph Supervising Officers attended:—

Misses J. Blackwood (Glasgow); L. Hartje (Liverpool); E. Hill (Birmingham); E Makin (Manchester); and H. Wallis (C.T.O.). Messrs. T. Barratt (Nottingham); G. Brown (Leeds); Mansfield Brown (Newcastle-on-Tyne); L. Burford (L.P.S.); B. Cadman (Liverpool); E. Fisher (Edinburgh); J. Gaiter (Aberdeen); G. Gibbs (Southampton); J. Hopgood (C.T.O.); G. Hutchinson (C.T.O.); J. Kermode (Dublin); J. J. Mansell (C.T.O.); C. Mansell (Plymouth); J. McKeown (Belfast); D. Miller (Glasgow); T. B. Morrall (Sheffield); R. Osborne (Birmingham); F. Riley (Bradford); D. Ross (Leicester); C. Sanderson (C.T.O.); G. Smith (Bristol); R. Stubbs (Hull); E. Tildesley (Cardiff); J. Wadsworth (Manchester); and R. Wright (Brighton).

At several of the sessions Mr. John Lee, Controller, and Mr. A. W. Edwards, Deputy Controller, Central Telegraph Office, were present and took part in the discussion. Members of the Traffic Section also attended.

Sir Evelyn Murray, K.C.B., Secretary to the Post Office, who was accompanied by Mr. F. J. Brown, C.B.E., Assistant Secretary (Telegraph Branch), in opening the Conference said that the usefulness and value of these Conferences did not begin and end in that room. They wanted to bring together for the common good the experience and knowledge of the traffic experts at Headquarters and the officers in charge of provincial telegraph offices. The quality of the telegraph service was now as good as, if not better than, in pre-war days. The number of complaints from the public was extraordinarily small and the British public had no false modesty about making complaints. If there was one qualification that could be made it was a doubt as to the efficient and economical organisation of the delivery service. The cost of the delivery service was about £1,600,000 a year, or about 5*d.* a telegram. On the question of economy, which was one of the burning questions of the day, one fact which was striking and disturbing might be mentioned. In the estimates for next year it was reckoned that the operating costs of the telegraph service would alone exceed by 1½ millions the telegraph revenue, that was to say, the revenue of the telegraph service would not be sufficient even to meet operating costs, let alone charges for depreciation, engineering costs, etc., and there was no prospect of a material increase of revenue to meet these charges. Any possibility of reducing or bringing that deficiency within measurable limits depended on economies that could be made. He proposed to revise establishments during the coming year and to bring them as far as possible into closer agreement with actual traffic requirements. He extended a cordial welcome to the representatives from provincial offices and expressed the hope that the Conference would be eminently successful.

The agenda was then proceeded with. Papers were read and discussed in the following order:—

"The method of supervision likely to promote the most efficient internal management of telegraph traffic. The desirability of specialisation on testing duties.

Test Records.

The treatment of telegrams at the enveloping stage, and the delivery of telegrams.

Telegraph Breakdown Organisation.

The extension of quadruplex 'simplex' working.

Telegraph Concentration."

Discussion throughout was animated and instructive. On completion of the agenda, the general consensus of opinion on the subjects discussed was presented in a series of conclusions, which were adopted unanimously.

The proceedings of a most successful and inspiriting Conference terminated with a cordial vote of thanks to the Chairman.

On the evening preceding the opening of the Conference a dinner was held at the Holborn Restaurant at which the provincial representatives were met by members of the Headquarters Traffic Section and many Supervising Officers of the Central Telegraph Office. A pleasing feature was the number of female Supervising Officers from the Central Telegraph Office present.

IMPRESSIONS OF THE 1921 TELEGRAPH SUPERVISING OFFICERS' CONFERENCE.

BY A PROVINCIAL REPRESENTATIVE.

After one's experience at the Telegraph Supervising Officers' Conference it is easier to understand why conferences are so prominent a feature in the life of every important organisation. From the very beginning of the Conference the elements without and the "powers" within vied with each other in making the day bright and pleasant for the delegates, and a most agreeable atmosphere was created in which unity of purpose and earnestness of spirit were to have free scope.

We were started happily on our deliberations by the Secretary, Sir Evelyn Murray, who welcomed us to Headquarters, and indicated some of the problems which were to have our attention; and towards the conclusion of the Conference we had some felicitous words from the Assistant Secretary, Mr. F. J. Brown, who told us also a little of the history of the Imperial Cable in the setting up of which, by the way, it is understood, he himself has played no inconspicuous part.

If before our meeting there was a feeling that the personnel of the conference fell into two distinct groupings—the Traffic Section and the delegates—the idea was dispelled early in the proceedings, as we all came under the genial and kindly influence of the Chief of the Traffic Section and his staff.

The blending process was initiated by "the welcoming handgrip and smile" given at the Conference Dinner to each and every visitor by Mr. Dalzell

Digitized by Google

and his officers, and the intervals for informal conversation brought the delegates to know each other more and more intimately, so that by the time the several courses had disappeared and the attractive musical programme had been disposed of any misgivings or anxieties as to the nature of the reception we should obtain at the Conference Room next day, vanished into the "Never has been."

A striking, and in the writer's opinion, a not unwelcome feature of the Conference was the large number of "set" speeches made by the delegates. No doubt this was a necessary consequence of the desire to express not merely one's own personal opinion on any subject but also the opinions held by other responsible local officers. Even if there is a certain amount of repetition involved, as offices of more or less the same standing have their similar local practices and customs described, it is probable that greater accuracy and clearer judgments are likely to be presented by prepared speeches on the main questions. Furthermore, as the discussion develops and new viewpoints present themselves notes can be most profitably made in the appropriate portion of the set paper. A query here or there may be answered before it has been asked and then of course it need not be put, or, as "iron sharpeneth iron" fresh queries may be suggested and can be readily inserted at will in a set speech.

The main papers—most of them written by the Traffic staff—first presented to our minds the Unity of Purpose which was a specially marked impression received from the Conference, and it was a happy direction of the Chairman that the several papers, although typed and circulated previously should be read by the gentlemen who prepared them. The respective personalities of the writers, their evident grip of the subjects, and their earnestness of manner gave added interest to the papers, and with the pervading spirit of brotherliness, already clearly apparent, produced on us the further impression that the Traffic Section was "built as a city that is at unity in itself."

"For thither the tribes go up——"

The tribes in this case being the Provincial representatives, and although I say it myself who am one of them, I think they would altogether be hard to beat for a gathering of delegates—eager and earnest and at the same time unpretentious: serious and thoughtful, and at the same time enjoying a laugh when as happened frequently a spark of wit flung out vibrations to excite our risibilities. From Aberdeen to Plymouth, from Dublin to Hull, from the north, east, west and south they came, each to bring his individual experience to the common meeting-place to have misunderstandings put right and to catch something of the spirit of progress in methods and manners.

The lady delegates, contrary to supposed traditions, left most of the talking to the mere males, but we felt at the same time that we owed no little part of the homeliness and pleasantness of the surroundings to their presence amongst us.

Finally, we were impressed with the recital of the many subjects which Mr. Dalzell told us were occupying the serious attention of the Traffic Section, and we all came away feeling that wherever our "daily round" took us our common task would never again appear mean, because we had been made to realise that in our lesser struggles with local problems we were to have, with those who handle the wider problems at Headquarters, one common air—the maintenance of the British Post Office Telegraph Service as the most efficient in the world.

A brief words of special thanks before we stop. First of all to the Chairman (Mr. Dalzell) who very thoughtfully arranged to release the delegates early on one of the afternoons in order that they might have an opportunity of seeing the several items of telegraphic interest in the Efficiency Exhibition at Olympia. Secondly, to the Controller for the pleasure of the visit to the Central Telegraph Office and for the provision of the several very patient and painstaking guides, and thirdly, to our Conference Secretary, Mr. A. P. Ogilvie and his enthusiastic colleagues for their untiring friendliness and helpfulness to the "Provincials."

If back again amid the old worries and duties we try to gather into a few words the broad lesson to be learnt from our experiences in Conference week, the following concluding lines may not be wholly inappropriate.

"With work, good cheer and kindliness and laughter up the sleeve,
This queer old world's not half so bad as some folk make believe."

PORTABLE TELEPHONES.

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

DEAR SIR,—I enclose a cutting from one of your brilliant and up-to-date contemporaries. (Our correspondent encloses a picture of a portable telephone described as a "Berlin invention" which enables subscribers to fix the instrument in any apartment they choose by means of sockets on the walls). It depicts and describes a piece of apparatus, the principle of which has been in use in this country ever since telephones have.

The fact that it is called an "innovation" is a delightful commentary on the knowledge of the subject described, and throws a light upon the methods of the critics who will even go to Germany for a 40 year old "novelty" as evidence of the superiority of other telephone systems over ours.

A. W. ROBINSON.

BAUDOT MANIPULATION IN ENGLAND AND FRANCE.

IMPORTANT CHANGES IN BRITISH OPERATING PRACTICE FORESHADOWED.

NEARLY all of the inland Baudot circuits of the United Kingdom, which now number 30, have been installed since the outbreak of the great war; therefore, the conditions as regards the staff available for training were in most cases abnormal. Excellent results were obtained, especially with the staff temporarily obtained for working the system, but with the return of staff from war service it was felt that with the restoration of the pre-war staff conditions certain operating problems would have to be considered. At the Telegraph Supervising Officer's conference of Jan. 1919, various questions relating to the Baudot system and the experiences at the different offices were discussed.

In a paper read before the London Telegraph and Telephone Society on Nov. 25, 1919, dealing with the Paris Telegraphs, Mr. H. Booker mentioned the method of manipulation observed while in the Central Telegraph Office there, pointing out that while the signalling looked laborious, the French operators remained at sending points regularly for four successive hours, and that the question of the difference of the British and French methods was worthy of a closer investigation.

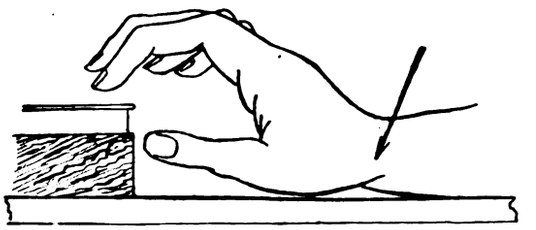

FIG. 1.—FIRST POSITION: THE WRIST IS THE PIVOT OF THE MOTION.

At the second Telegraph Supervisors' Conference it was recommended that something should be done in the direction of regularising the Baudot training which had been determined largely by local circumstances.

A conference was appointed to consider the matter under the presidency of Mr. John Lee, the Controller of the London Central Telegraph Office.

The Conference visited certain provincial towns and observed that each of them had a general style peculiar to its own office, and that not one of them quite agreed with the methods adopted in the other offices.

Moreover, it was very evident that few, if any, were altogether free from objection, and in general the Baudot signalling showed decided tendencies towards styles which were cramped and restricted.

Much useful information was obtained from Baudot operators, from learners, dirigeurs and instructors, and valuable assistance was rendered by U.P.W. representatives.

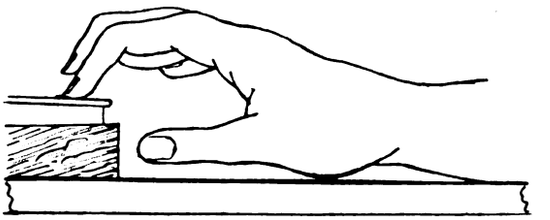

FIG. 2.—SECOND POSITION: THE WHOLE WEIGHT OF THE HAND SHOULD ACTUATE THE KEYS.

The inquiries tended to show that in some cases operators have been passed as qualified for handling traffic at too early a stage and had drifted into questionable practices both as regards posture and manipulation—not infrequently these could be traced to the learner having imitated a style practised by an expert operator whose style was open to serious objections.

The conference deliberated upon the collected evidence and it was realised that a freer style of manipulation was essential. Also, that while such a system of Baudot manipulation would promote efficiency, the interests of the staff would be advanced by the adoption of a method of sending which would ensure greater freedom in posture and in signalling inasmuch as it would prevent the appearance of such disabilities as have been very difficult to remedy in the case of Morse telegraphy.

Digitized by Google

It seemed desirable that the conclusions at which the Conference had arrived should be correlated with the opinions held by the French Administration with its longer experience of the Baudot System.

Accordingly it was arranged that Messrs. A. B. H. Brown and H. W. Pendry should visit Paris and discuss the various questions with the experts there.

In the absence of M. Broin, Directeur, at Washington, U.S.A., M. Marignac, the sous-Directeur, very cordially arranged for every facility to be given to the visitors. M. Goerens, chef du Poste Central, arranged for M. Dubreuil, a

FIG. 4.—POSITION OF BAUDOT OPERATOR SHOWING THE PLACE OF KEYBOARD.

member of the technical staff, and a colleague to give them personal attention. These gentlemen spared no pains to impart information and make the visit eminently successful, and it is also pleasing to record that the delegates were able to reciprocate by answering many questions relating to the British practice.

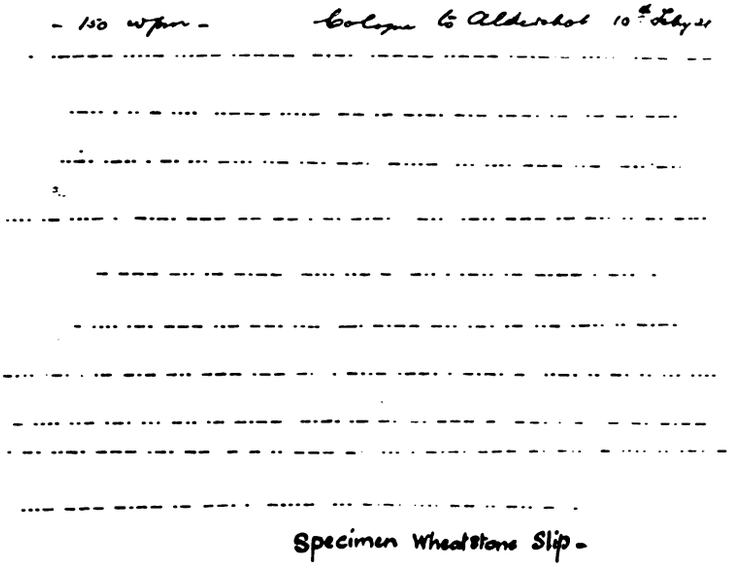
A long interview with M. Mercy, the well-known Baudot expert and author, was exceptionally valuable, as he explained very fully the present operating and teaching methods and the reasons for their adoption.

FIG. 3.—POSITION OF BAUDOT OPERATOR (FRONT).

Visits to the instrument rooms and school showed that the style of manipulation practiced by the Paris operators, while not altogether uniform was, almost without exception one of great freedom. Generally speaking the keyboard was placed well back from the edge of the table, the forearm rested lightly on the table and the elbows were maintained away from the sides of the body. Most of the French experts expressed preference for the separate movements of the hands for each signal. It was observed that the operators touched the keys near their extremes, thus taking full advantage of the leverage. Almost all of them depressed the keys with the tips of their curved fingers and the whole of the hand was moved from the wrist, while none of the fingers rested at any time on the woodwork of the keyboard (see Figs. 1 and 2.)

It was confirmed that all of the operators send continuously for four hours as an ordinary duty, and frequently for longer periods. The officer who was good enough to sit for the photographs (Figs. 3 and 4) obtained the first prize at the Turin Tournament of 1911 for Baudot manipulation, and he used regularly to send for seven and eight consecutive hours. He emphasised the need for an operator to assume a comfortable position on the chair and preferred a position of the chair quite close to the table. His keyboard was found to be 11½ inches from the table edge. The arms were rested easily upon the table and made contact therewith from the elbow up to a point near the wrist, from which point onwards both hands were quite free.

The report of the delegates confirmed the views already held by the Conference and certain rules for the Baudot keyboard manipulation will no doubt be issued very shortly (perhaps before this article appears).



Some idea of the new principles may, however, be formed from the points mentioned in the foregoing article and its illustrations.

H. W. P.

WIRELESS WHEATSTONE TRIALS.—ALDERSHOT—COLOGNE.

"Very considerable improvement will be made now (February 1921) in the telegraphic system and record wireless messages will be sent and received."—vide *Old Moore's Almanack.*

That high-speed wireless working has made and continues to make great strides, is an accepted fact, and anyone who may have had doubts regarding the utility of Wheatstone for such transmission of telegrams would have been rudely awakened could he have been present at either Cologne or Aldershot Military Wireless Stations a week or two back. For in order to test the accuracy of Wireless Wheatstone working it was arranged for Wheatstone staffs from the Central Telegraph Office to proceed respectively to Cologne and to Aldershot and to work between those places with telegrams prepared in advance. And here it should perhaps be remarked that such an arrangement was not made in order to justify the prognostications of "Old Moore," whoever he may be.

To enable the number and percentage of fundamental, as distinct from, operating, errors, to be ascertained, it was arranged that the operators at both ends should transcribe the signals as received, and obtain the necessary corrections, showing both upon the relative message forms. By this method it was sought to show the total number of errors, and thus to gauge the practicability of the system in actual working. Copies of the telegrams sent from Aldershot were conveyed to Cologne and *vice versa*.

The Military Wireless Station at Cologne is situated at Riehl some three miles distant from the Rhine Army G.H.Q. Signals Office in Deichmannhaus (facing the Cathedral) by which it has connexion by wire. Wheatstone apparatus is installed there, and signals were relayed thither from the Wireless Station at Riehl a special Trigger valve being employed. At the Wireless Station a 1½ kilowatt Valve Transmitter is used, and signals on a 1,600 metres wave-length were received and transmitted. The trials took place over a

Digitized by Google

period of three days, in the morning and afternoon on two of these, and in the late evening hours on the remaining day, atmospherics being known to be more prevalent during evening and night working. Fifteen minute period of transmission and reception were arranged for, with fifteen minute intervals, to allow of necessary repetitions being obtained. Some difficulty was at first experienced, but conditions improved vastly later, when perfect signals at 100 words per minute were obtained. Indeed, so successful was the working at this rate of speed that trials at 150 words per minute were made with complete success, and a succession of messages were received at Aldershot without a single repetition being required.

It speaks volumes when it is stated that of the 575 telegrams transmitted to, and 478 received from, Aldershot, a total of 1,053, only seven per cent. did not altogether correspond with the typed copies of the original telegrams, the remaining 93 per cent. being correctly received. Of the 150 messages requiring correction, 9 per cent. of the errors were attributed to atmospherics, 6.5 per cent. to operating errors and the balance to valve troubles, apparatus faults, etc., So perfect were the signals that had Creed apparatus been installed Creed working could have been successfully achieved.

A facsimile of the Morse signals as received at 150 words per minute is given.

The trials demonstrated the possibilities of Wireless Wheatstone working between London and Cologne, and the utility of such as an auxiliary to the existing Cable and land-line service in times of pressure and interruption. Wireless Wheatstone would also have the added advantage that without the installation of Wheatstone apparatus it would not be possible to "listen-in" as is the case with key working.

A. W. EDWARDS.

THE BAUDOT.—XIX.

AT the left hand bottom corner of the front of the receiver and in close proximity to the impression wheel V^1 (Fig. LV), and its companion the typewheel, is fixed a rectangular brass plate P. This plate is screwed to the casing P^1, see Fig. LIV, which gives a sectional view of the parts about to be described. A short, shouldered axle (Figs. LIV and LVI A", and LV S) is screwed firmly on to the plate P. Fitting easily upon this axle is a metal sleeve *l* (Figs. LIV to LVI). Upon the inner side of *l* and at right angles to it is a steel prolongation known as the impression arm *b* (Figs. LIV, LVI), tapering to a rounded end. Just behind this arm is a triangular cam piece H (Figs. LIV to LVI) maintained in position on *b* by three countersunken screws 1, 2 and 3 (Fig. LVI). H is provided with a heel piece *t* and a triangular spur *a*, and itself terminates in a pointed edge *f*. The latter is capable of engagement with the teeth of the impression wheel. When at rest the edge *f* of H remains in position close to the rotating *impression* wheel, which regularly presents its notched periphery before it.

Upon the sleeve *l* is lightly fitted a small steel drum *l'* which carries a ratchet wheel G round its inner edge (Figs. LIV to LVI). Firmly fixed over the drum *l'* is another sleeve *l"* with two roughened channels cut round the outer edges of its circumference. The drum *l'* and the sleeve *l"* are together known as the *impulse* cylinder.

Another cylinder, the *compression* cylinder, is shown *z* (Fig. LV). It is centred at *x* on to an axle fitted with a spiral spring and screw R, which retains *z* against the impulse cylinder. A small handle *h* moved in the direction of the arrow permits the raising of *z* from the impulse cylinder and the insertion of the paper tape necessary for printing.

The threading of the tape is shown in Fig. LV by means of heavy lines round the paper-guide T^1 the pin-guide T, then round the *impression* cylinder, and in between the *impulse* cylinder and the *compression* cylinder, and then, as indicated by the arrow, out in the direction of the paper-shoot N.

When mounted upon *l* the ratchet wheel of *l'* is engaged by the flat spring and click K, K, fixed on the upper part of the impression arm *b* (Fig. LVI) and known as the *impulse* click and by a second click and spring K^1K^1 (Fig. LV) which in their case are fitted to the support of the powerful U-spring E. K^1K^1 bear the name of the *retaining* click and spring.

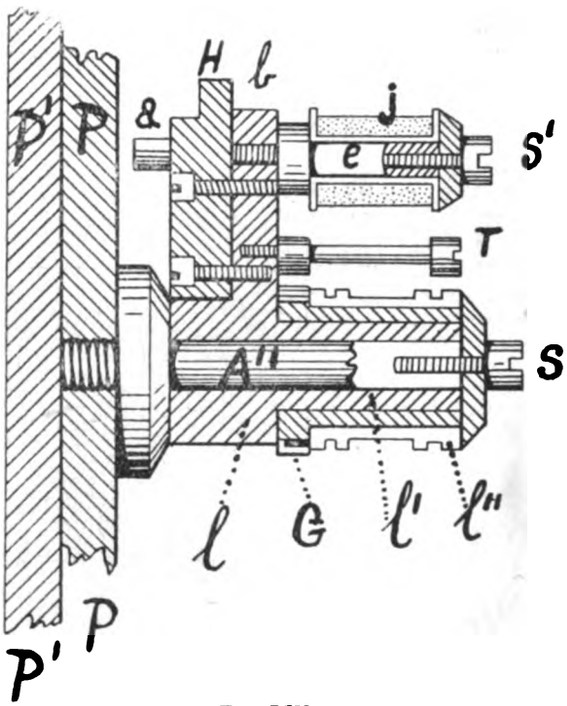


FIG. LIV.

At the extreme end of the impression arm *b* (Fig. LVI) is a smaller axle *e* upon which, capable of free rotation is a troughed cylinder called the *impression* cylinder *j*, which is filled in with gutta percha, paper, or similar resilient material (Figs. LIV to LVI). T, is the pin guide already mentioned. A grooved metal wheel, into which is fitted a removable circular pad of inked felt, rotates over the periphery of the typewheel under the pressure of a spiral spring, and thus inks the embossed letters ready to come in contact with the paper band. S, S^1 are screws which retain the cylinders upon their respective axles.

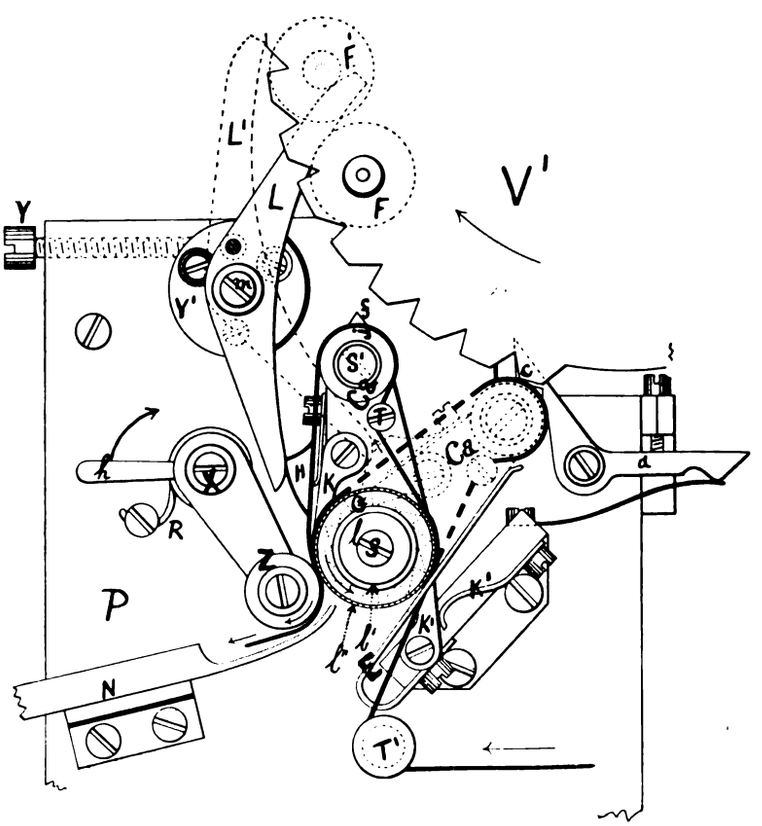

FIG. LV.

Digitized by Google

We are now in a position to study the sequence of movement following on the release of Ca (Figs. LI, LV), by the click *c* moved by the action of the pedal and other levers already described.

As soon as the retaining click *c* of the lever *d* is jerked backwards it releases hold of the spur *a* (Figs. LIV, LVI) fixed to H which forms a solid part of the entire impression movement Ca. The latter impelled by the U-spring E is thrown to the left upon its axle A″ (see also S, Fig. LV), and in the same direction as that of the rotating impression wheel V^1. The release of Ca is so timed as to permit the engagement of the portion *f* of the cam H (Figs. LIV to LVI) between two of the impression wheel teeth and the impression wheel V^1 in its rotation therefore carries the arm Ca with it to a position, indicated in heavy lines in Fig. LV, free of V^1. As the

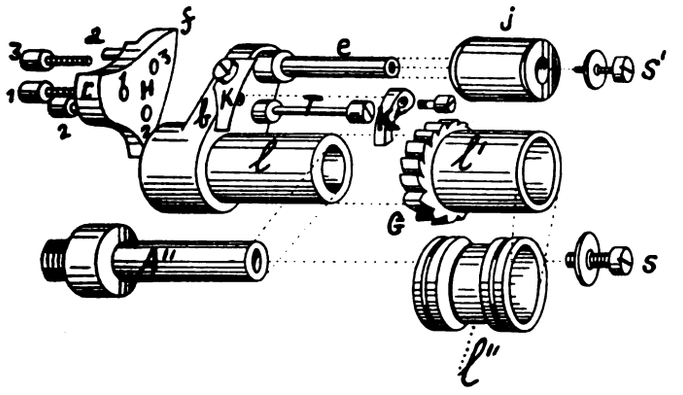

FIG. LVI.

typewheel and V^1, the impression wheel, rotate together the movement of Ca immediately in front of the lettered periphery of the former permits of a rolling movement of *j*, the impression cylinder (Figs. LIV to LVI) against it thus printing the desired letter. This done Ca remains in the indicated position free of V^1 until the unlettered 9/40 of V^1 comes round when at that very instant a roller F (Figs. L and LV) mounted on the back of the impression wheel V^1 meets the upper portion of an oscillating replacing lever L and throws the latter back on its axis *m* into the position F^1 L^1. This action causes the lower portion of L to strike forward against the heel-piece *t* of H (Figs. LV, LVI) thus pressing back the entire impression movement Ca and again locking the spur *a* of H with the retaining click *c* of the lever *d*.

The axis *m* of the lever L is mounted on a circular platform Y^1 (Fig. LV) which latter is screwed to the brass plate P, by three screws and slotted openings. By means of the latter and a long screw Y, which passes through the thickness of the Plate P itself, the position of the platform Y^1 and the lever L may be adjusted as regards the exact striking distance of L and the heel of the cam H.

(To be continued.)

REVIEWS.

"*Plain Economics.*" *By John Lee, M.A.* 110 *pp. Sir Isaac Pitman & Sons.* 3*s.* 6*d. net.*—Mr. Lee's work has for sub-title "An examination of essential issues," and it proceeds in simple and straightforward terms "to make some complicated issues plain." Economics the author describes in short as the science of making our living; that is, he explains, not my living but our livings mutually. It is strange, therefore, that a science which touches all men so nearly is so little studied. Indeed, to many, economics appears a formidable subject not lightly to be grappled with, or one touched on sparingly in the higher stages of education and soon forgotten. In a series of instructive chapters, this short book deals with theories of exchange and value, and describes the chief factors in production, explains Spending and Consumption, Currency, Credit, Competition, Guild Socialism, and the Economics of the State, and touches helpfully on all those burning questions with which the subject bristles.

Mr. Lee makes a plea in his last chapter for a fusion of theories. After showing how Individualism has had its day and how Bureaucracy, Socialism, and Communism do not provide altogether acceptable economic remedies, he comes to the conclusion that a new science of management with closer regulation of profits, and a closer interest of the State in methods of ownership and obtaining capital indicate the next lines of development. Co-operative effort and pride in our craft will lead us not to undervalue our work and to spend our leisure more worthily, for after all, as he says, man does not live by economics alone. In the chapter on "The State and Benevolence" he says very happily "Alms as a system brought the best impulses forth with the worst results," and in reference to Society accepting the heavier burden in support of the weaker, which makes heavy demands on those who have more means: "If the toss of a coin to a mendicant establishes some sort of claim to the Kingdom of Heaven, we shall be able to say in our day that the prompt payment of a demand for taxes makes a similar claim. It is less picturesque." In another place we note that Mr. Lee says that legislators all the world over are not at all certain that it is desirable to arrest the influence of the "combine." We venture to suggest that this may be because constituent members of combines are largely members of legislatures "all the world over."

"*Elementary Telegraphy.*" *Second Edition Revised. By H. W. Pendry, author of the "Baudot Printing Telegraph System."* 7*s.* 6*d. net.*—This book contains over 200 pages of clearly printed matter, with nearly the same number of illustrations, and can be well recommended for the use of the elementary student.

A valuable account of accumulators, construction of aerial lines, manufacture and description of air-space cables, and an elaborate explanation of central battery circuits, now so widely used, are included in this handy technical volume.

A somewhat unusual feature is the inclusion of a number of questions at the end of each chapter, dealing with its contents. This should enable the student to commence his training for the examination from the beginning of his studies. The appendix contains questions set at the City and Guilds of London Institute Examinations, Grade I, from 1908 to 1920 inclusive.

The whole of the elementary ground is covered in a masterly and readable manner with a thoroughness in keeping with this well-known teacher, and writer of the "Baudot Telegraph System."

A perusal of this book by Service members other than students, should prove of value in the acquisition of valuable hints and information not generally contained in text books.

"*Wireless Telegraphy and Telephony.*" *An outline for electrical engineers and others. By L. B. Turner, M.A., M.I.E.E. Published by the Cambridge University Press.* 195 *pages. Price* 20*s. net.* The object of this book, as stated in the preface, is to provide persons who are neither wireless operators nor specialist wireless engineers, but who occupy an intermediate position between these classes, such, for example, as electrical engineers who have never studied this particular branch of their general subject, with a brief account of the present position of wireless telegraphy and telephony.

The whole ground of modern wireless telegraphy and telephony is covered, although owing to the limits of space only an outline sketch of the subject has been possible. After an introductory chapter, in which the general principles of the subject are explained, there follow chapters dealing with electromagnetic radiation, oscillatory circuits, the production and the detection of high frequency alternating currents, the thermionic tube, the use of the triode as amplifier, rectifier, and oscillation generator, retroactive amplification and rectification, and wireless telephony. The

Digitized by Google

concluding chapter deals with several important miscellaneous points which could not conveniently be dealt with in the preceding sections.

The book is characterised throughout by the extremely clear-cut presentation of the subject to which those who have read any of the author's previous contributions to the literature of wireless telegraphy will be accustomed. Although the book cannot be called a mathematical treatise, the author has not hesitated to introduce mathematical reasoning where this serves to facilitate the explanation of any point. The mathematics are, however, in no case beyond the scope of an engineer with an ordinary mathematical training.

The book is well arranged, the printing and paper are good, and the diagrams and plates are extremely clear. Most persons have experienced at one time or another, when reading a portion of a book which necessitated frequent reference to a diagram, the annoyance of having continually to turn to and fro between the diagram and the text, owing to one being on a different page from the other. The diagram illustrating the action of the Poulsen arc has a considerable amount of text referring to it, and to avoid the difficulty mentioned, it has been printed twice, on successive pages, so as always to be in view while the text referring to it is being read. This is a very good point in the get-up of the book, and we wish it were more often adopted by publishers.

For a first edition the number of printer's errors which we have noticed is very few.

In discussing the relative advantages of signalling on a Poulsen arc installation by the use of a back-shunt or of a spacing wave, the author says that the use of a spacing wave is objectionable because power is being consumed just as much during spacing as during marking. This would lead the reader to infer that with the back-shunt power is not being consumed during spacing, which, of course, is not the case.

In the discussion of the triode as oscillation generator, the argument in the third paragraph on page 130 is not clear. It would seem that some words have been omitted by the printer from this paragraph.

In connexion with the design of a wireless telephone system with which two correspondents can converse with the same ease as with an ordinary telephone, the listener being able to break in and interrupt the speaker when necessary, the author uses the description "duplex" wireless telephony" for such a system. In a footnote he says: "A 'simplex' connexion is one along which communication can pass in only one direction at a time. A 'duplex' connexion carries communication in both directions simultaneously. *The ordinary line telephone provides a duplex connexion.*" (The italics are ours.) We are afraid that a sending and a receiving clerk at each end of an ordinary line telephone, endeavouring to carry on communication in both directions simultaneously, would not succeed in passing much traffic!

On page 171 certain percentages for antenna efficiencies are given as 12 per cent. and 25 per cent. respectively. These should apparently be 14 per cent. and 33 per cent. respectively.

The foregoing are the sole adverse criticisms we have to offer. The book is a really excellent outline of the subject, and we have read it with great pleasure. We are certain that, if Mr. Turner could find time among his multifarious duties to produce a larger treatise on the same lines, but going more fully into the subject, it would meet with a warm welcome.

"Introduction à la théorie des Courants téléphoniques et de la Radiotélégraphie. By J. B. Pomey, Ingénieur en chef des télégraphes. With a preface by A Blondel, membre de l'Institut. Published by Gauthier-Villars et Cie, Paris. XIV. + 509 pages.

This volume constitutes an advanced course on the physics of telephone transmission and wireless telegraphy.

The author makes free use of vector calculus, but as many telegraph engineers are not familiar with this powerful branch of higher mathematics the first chapter of the book is devoted to a very useful, though necessarily brief, sketch of its principles. The whole field of the fundamental theory upon which modern ideas of telephonic transmission and wireless telegraphy are based is then covered, the various problems involved being dealt with in a remarkably thorough and logical manner. One chapter is devoted to a discussion of the theory of the catenary and of the other mechanical points involved in the construction of wireless aerials and their supports.

We are disappointed to see that the author has not touched upon the thermionic valve. Possibly in a later edition a chapter will be added dealing with this important subject.

Otherwise the book is remarkably complete, and we are sure that it will be found of great use to wireless and telephone engineers and others interested in the higher branches of the subject.

TELEGRAPHIC MEMORABILIA.

THE Annual Report of the Post Office Relief Fund published towards the end of February and giving the certified balance sheet for the year ended Aug. 31, 1920, is an interesting and gratifying document, in that it shows a decrease on the liabilities of the fund as compared with the preceding year of over £500, *i.e.*, £22,073 as against £22,627. This result is more satisfactory even than the figures would appear to declare, as under the Committee's scheme for the Secondary Education of orphans there is a steady increase in the number of children benefiting owing to the number of dependent children coming within full educational benefits due to the efflux of time. The nominal value of investments held in August last, alone reaches the remarkable figure of £314,735.

Somehow or other the appointment of Lt.-Col. A. F. H. S. Simpson, C.M.G., R.E., late Director of Wireless to the Indian Telegraphs, to a seat on the Boards of the Marconi Companies has been overlooked. The connexion of the Lt.-Colonel with wireless interests is of no recent date. As far back as 1905-6 he could have been seen in his Alipore headquarters near Calcutta, well alive to the future of this branch of telegraphy. He will, doubtless, recall how in those earlier days one of their high teak masts was suddenly swept away in a hurricane, snapped off like a carrot close to the ground, the stays being torn out of the earth, and the whole being carried out to sea, lost for ever to sight and knowledge.

So significant an event as direct wireless working between London and Berlin by means of Creed apparatus could not indeed be passed over without something more than the mere recitation of the fact. It marks a noteworthy milestone along the road. The communication is of course an expensive one, as it entails the up-keep of the Stonehaven wireless station practically as a "repeater" office, and the utilisation of a wire between London and Stonehaven as a speaking circuit. That there are interruptions is of course natural—Moscow bumping in now and again, for example—but then interruptions are by no means unknown on the older system of utilising metallic conductors. It is understood that the London end of the—what shall we write in place of "wire?"—will shortly terminate in the Cable Room, an allocation proper to Anglo-Continental circuits.

I find that very few of my acquaintances have read the particularly lucid articles on "The Wonders of Directional Wireless" by W. H. Eccles, a scientific expert of no mean repute, which appeared in the *Daily Telegraph* of Feb. 11. The article had special reference to Directional during the late war. The chain of directional wireless stations established by Capt. H. J. Round, of the Marconi Company, and others, and extending along the East Coast of England, enabled the British, and as also, let it be placed on record, a similar chain of stations established by German engineers in Belgium and North-West Germany, enabled the Germans to locate the position of hostile air-craft, sea-craft, &c. It was not, be it understood, so much that the messages themselves invariably conveyed the desired information, but that the strength of those signals as reported by three or more observing stations were utilised by a process of triangulation to determine the exact locality of the origin of those signals at the *observed* stations. The locality of German submarines and German air-craft was repeatedly obtained by this means. With regard to air-craft, Mr. Eccles remarks that the work of British observing stations, "was more successful with Zeppelins than with aeroplanes, probably on account of the fact that the antennæ used by aeroplanes in transmitting messages are greatly inclined from the vertical."

The German method of determining the position of their own aeroplanes or Zeps, consisted, continues the writer "in the aircraft sending signals so that two or more German land stations might determine its bearings; these stations compared their measurements (*using land lines*), and then telegraphed the result back to the plane or airship. The Allies, on the other hand, worked by other means. Certain land stations or wireless beacons transmitted signals, which were picked up by a loop antennæ on the aircraft, and the observer, by plotting the bearings of these known stations on a map, was able to

Digitized by Google

determine his own position. The advantage of this method was that the aircraft remained perfectly silent, and therefore did not give its position away to the enemy.

"An interesting story is told of the German method of position finding. It occurred in the Mediterranean, where two of our anti-submarine watching stations, *not connected by cable*, were forced to exchange observations by wireless, thus disclosing their existence to the Austrian submarines. On one occasion an Austrian submarine came to the surface, asked our watching stations to determine her position, sent a string of signals for them to observe, waited for them to deduce and telegraph the reply, thanked our watching stations, and disappeared!"

The necessity for the co-operation of *wire* telegraphy in these defensive measures will be quickly understood by certain "T. & T. J." readers who, either in a civil or military capacity during the late stressful years were in close association with the various arms of the Services concerned. To these the special stress of my italicisation of the above three and four words respectively, will not be necessary.

This altogether engrossing account concludes with references to the peace-time applications of this entrancing phase of wireless, some of which have already been more or less skeletonised in these columns from time to time. The contemplated *radio-phares* of the French, for example, by means of which vessels properly equipped may determine their own positions, warnings upon approaching dangerous coasts during foggy weather, &c.

His final paragraph treats in a few words of the possibilities of duplex wireless over long distances which many readers may not know is arranged as follows:—Each terminal is equipped as a transmitting and receiving station as is the case, let us say, in a duplex sounder circuit, but in the case of long distance duplex wireless, from these islands to America for instance, the transmitting and receiving stations would be separated a considerable number of miles, probably 40 to 50, the receiving and sending stations being connected by a couple of wires or one line duplexed so that the necessary RQS, &c., could be exchanged.

The use of *directional* wireless in duplex working is essential for, "the receiving station has a loop antennæ, and is therefore directional; this is arranged so that it is broadside on to its transmitting station and edge-on to the distant station to which it is listening. When this principle is applied at both ends it is possible for the operators to read the signals from a great distance, while the relatively near-by transmitting station is simultaneously sending messages; each receiving station, in fact, turns a deaf ear to its transmitting partner."

The difference between the duplex use of *directional* and the war and peace time uses of the same phase of wireless is simply that in the latter the loop antennæ is stationary, only having one definite station for its correspondent.

The following excerpt from that staid but always interesting weekly, *The Observer*, strikes in a pleasantly humorous manner the psychology of the telephone and the public, or the public and the telephone, whichever may be the correct order of seniority.

"Even in the average circumstances of speaking through the wire or attempting speech, the drawbacks are marked and irksome by comparison with other inventions. If you get the wrong train or miss it, that is your own fault except in the rarest cases. But in ringing up it is not your fault if the number is engaged or you are given a wrong one. Then, unlike all the other devices, the telephone can hit back. You are not safe. No locomotive engine with railway carriages ever paid you an unexpected and unwelcome visit. That liability would be a contingent nightmare in every street. It is entirely in your choice and discretion as part of your proper business to catch a train; but upon the initiative of all and sundry the telephone may catch you whether you like it or not; and it may be on their business to the prejudice of yours and the bootless loss of your time. Useless letters you can throw into the fire or the basket. Telegrams can be read in a moment. Human nature at its most eccentric rarely sends wholly irrelevant or intrusive telegrams. But on the telephone you may find yourself the prey, and even the protracted prey, of bores whom you do not know; or otherwise the victim of unseasonable interruption. Human civility forbids you to cut off the futile call with abruptness as you can throw away the useless letter or telegram."

There will be subject matter for another leaderette when the general public have the automatic system at their elbow, and when, therefore, there will be no one but the caller to blame for "wrong number" or "wrong exchange!"

There is another invention which has reached a practical stage and which may be attached to any subscriber's telephone. It was, I believe, invented by a German—before the war—and is now either on or about to be placed on the market. It answers to some such horrid name as "Telegraphone," and is a combination of (1) a telephone, (2) a dictaphone, and (3) a gramophone. If the subscriber wishes to leave his office he simply switches the apparatus on and hurries off. Should the subscriber be called during his absence, No. 3 replies, "I am Victoria 4762, Mr. Cuthberton-Smith is out. If you wish to leave a message for him, please speak." Then there is a gurgling noise and the dictaphone comes in circuit. We will not be rude enough to intrude into the secrets of the dictaphone cylinder as to the nature of the reply, nor will we utilise our imaginations in so hopeful a sphere!

Our contemporary, *Truth*, in an apparently honest endeavour to give some measure of credit to government organisation recently printed the following paragraph in its columns:—

"Nowadays, when it is the fashion to tilt at everything run under Government control, it is refreshing to hear of an instance where the Post Office offers a service cheaper and quicker than a private commercial concern. A correspondent wishing to communicate with a ship sixteen hours out from Marseilles applied to the Marconi Company, who informed him that owing to delays on land lines, it was unlikely that the message would reach Marseilles before the ship, the reason being that messages are sent over the ordinary cables to the wireless station nearest the addressee and thence wirelessed. The charge was to be 10½*d.* per word. He then inquired of the Post Office as to the chances of speedy delivery of a telegram to the ship on arrival. He was informed that the message would get there in good time and the charge would be 2½*d.* per word, the reason being that *the Post Office uses wireless from London to Marseilles, while the wireless company uses the land cables.* What the reason may be for this paradoxical situation is altogether beyond me."

The italics are mine, together with the writer's sympathy for the paragraphist of the well-known weekly. It would be interesting to hear the explanations of the counter-men of both the Marconi and the Post Office who are alleged to have given the above "information"

No attempt will be made to dis-entangle this maze of thread, but it may be here and now stated most definitely for the benefit of both the Marconi and Post Office officials that the reason for the more expeditious treatment in the case of this particular 2½*d.* route is the fact that there exists a direct telegraph *wire*, open day and night, between London and the port of Marseilles.

A personal apology is due to my personal friend, Mr. Murray, for a slip of the pen in the March number of the T. & T. JOURNAL, wherein mention was made of "The new Baudot distributor, connexion box and pin connexions." Of course, except for the fact that it has a Baudot type of distributor, the apparatus to which my remarks referred was the Murray Multiplex now being installed on the Belfast circuit. As a matter of actual fact my attention was specially taken up with the neat pin connexions and general compactness of the *altogether* of it, as the French would say, and I did not pay quite the attention, &c., &c., but there, I am confident Mr. Murray will understand.

All members, past or present, of the late Submarine Telegraph Co., the old "F.G." and the newer Cable Room, C.T.O., will regret to hear of the death of Mr. W. G. Clark, known to many as "Werter," at the East Sussex Hospital, Hastings, on the 7th of last month, from pneumonia.

He had been pensioned nearly ten years, having retired from the Service on June 5, 1911. Mr. Clark served his apprenticeship in telegraphy with the late Submarine Co., commencing duty with them in October, 1868. Of a stolid, plodding, yet genial nature, he had an individuality singularly his own.

J. J. T.

TELEPHONE DEVELOPMENT OF SOUTH AND CENTRAL AMERICA.

Dr. Victor M. Berthold, the chief Foreign Statistician of the American Telephone & Telegraph Co., who has for the last seven years devoted himself exclusively to the study of telephonic and telegraphic development in South and Central America, has kindly forwarded to me some recent statistics relative to the American Republics. The figures given in my recent article (page 70) were admittedly based on pre-war figures, as, except in the case of Buenos Aires and Monte Video, later information was not obtainable. The following are the statistics for Jan. 1, 1919:—

South America.

	No. of stations.
Argentine	105,205
Bolivia	2,650
Brazil	67,366
British Guiana	1,214
Chile	23,670
Columbia	5,263
Dutch Guiana	436
Ecuador	3,626
French Guiana	173
Paraguay	190
Peru	7,148
Uruguay	19,486
Venezuela	7,437
	243,864

Dr. Berthold estimates a present population of over 63 millions, which means that there is 1 telephone to every 259 inhabitants of South America. Buenos Aires had 54,676 stations, Rio de Janeiro 23,510, Monte Video 11,216, and Santiago (Chile) 6,554.

Central America and West Indies.

Mexico had 40, 211 telephones (with 19,491 in Mexico City), Cuba 27,765 (with 20,057 in Havana), Panama 4,734, and Salvador 2,404. Costa Rica, Guatemala, Honduras and the Dominion Republic had each over 1,000 telephones. The figures for Central America in my paper should be increased to 11,648, and for the West Indies to about 30,000. W. H. G.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.1. The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. APRIL, 1921. No. 73

TELEGRAPH AND TELEPHONE SOCIETIES.

Now that the season of the London Telegraph and Telephone Society is coming to an end it is opportune to draw attention to the valuable services which this Society has rendered in the discussion of questions affecting telegraph and telephone procedure and organisation. All the more it is a great pity that similar societies which have been established in the provinces have not been as successful as might have been wished. There is a wide range of subjects open for discussion and many points of view from which they can be discussed. It might be possible to arrange for papers which have been read by one society to be read at another in order that further discussion might be encouraged. We should be glad, also, to find room in this JOURNAL for papers which are read at provincial Societies equally with those which are read by the London Societies. There are many reasons why practice and experience must differ in different towns. As regards telegraphs there are local differences in respect of the incidence of traffic which might open up discussion of comparative procedure. We can quite believe that the cotton traffic in Liverpool, the fish traffic at Aberdeen or Grimsby, the Stock Exchange traffic at all large towns, and Football Zone and Cricket Zone systems all offer scope for enlightenment from the provincial point of view. Similarly in respect of telephones we imagine that Leeds might have special contributions to offer from its experience with automatics, that the Liverpool-Manchester and Glasgow-Edinburgh routes which have each special characteristics might also be a valuable basis for the discussion of rapid telephonic service. In fact it might be possible to have the same questions discussed at different societies, and by the change in the point of view to elucidate them far more thoroughly than has yet been accomplished.

Apart from this practical result each discussion itself is of enormous value. It gives us an objective vision of our own service; it widens the purview; it enables officers who have given special study to particular aspects of telegraph and telephone procedure to give us the benefit of that study. In a word it raises the whole worth of our calling. We can imagine for instance a number of provincial telegraph and telephone societies being anxious to hear Mr. Avery's paper on the Imperial Cable Service, for that service is of immense importance not only to London but to the country at large. If any of our provincial brethren are interested in the organisation of Telegraph and Telephone Societies, we are perfectly certain that the Secretary of the London Society, Mr. Stuart Jones, will be ready to afford all information, and we understand that if it is decided that particular papers already delivered to the Society in London would be of help to Societies in the provinces arrangements can easily be made for them to be delivered to these Societies.

THE WONDERS OF WIRELESS.

READERS will have noticed during the last few months that an increasing part of our space has been occupied by information about the developments of wireless telegraphy. In the present number, Mr. A. W. Edwards tells us how old Moore's prophecy has been realised, and our old friend J. J. T. gives himself over to an eulogy of telegraphy without wires to the extent of half of "Telegraphic Memorabilia."

This child of tender years indeed shows exceeding great promise. The developments during the war have been great, but the scientific dreamers of dreams to whom civilisation owes its greatest triumphs have visions of applications of Hertzian waves which are almost alarming in their possibilities. If even a few of the dreams are translated into actual fact, the development of the child to puberty and manhood will be one of the triumphs of the present century. But a few years ago, "wireless" was regarded more as a scientific toy; but, with the passing years and the development of thermionic valves, improved methods of detecting, and magnifying, both transmission and reception are now commercial facts, hindered as they may be by difficulties of direction and by interference from jamming and atmospherics.

One school of thought has already cast doubt upon the electron theory and even on the very existence of the æther, by means of which the Hertzian waves are said to be disseminated, while another claims to have succeeded in weighing and measuring what has hitherto been regarded as without size or weight. We shall no doubt each follow to the limit of his understanding these great scientists in their lofty flights into the realms of the unknown, and endeavour to arrive at some mental picture of the results.

To the student whose early teaching is overthrown by the later theories of science, the new terms, the infinitesimal measurements and the new functions of familiar objects are confusing, and we are, therefore, glad to announce that we have secured for early publication a series of fully illustrated articles on modern wireless telegraphy and telephony by Mr. F. Addey, B.Sc., M.I.E.E., Fellow I.R.E., whose name is familiar to many of our readers. These articles will probably commence with our May number.

HIC ET UBIQUE.

THE following are the members of the new Select Committee "to enquire into the organisation and administration of the Telephone Service and the method of making charges":—Rt. Hon. Evelyn Cecil (E. Herts, C.U.), Chairman; Evan Hayward (S. E. Durham, Liberal), Solicitor; Rt. Hon. John Hodge (Gorton, Lab.), President, Iron and Steel Trades' Confederation; G. F. Hohler, K.C. (Gillingham, Unionist); J. Stanley Holmes (N.E. Derby, Liberal), Chartered Accountant; General Sir Archibald Hunter (Lancaster, C.U.); Sir Evan Davies Jones (Pembroke, C.L.), Public Works Contractor; R. J. Lynn (Woodvale, Belfast, Unionist), Editor, *Northern Whig*; Lane Mitchell (Streatham, C.U.), twice Mayor of Camberwell; Captain A. H. Moreing (Buckrose, C.L.), Mining Engineer; W. G. Perring (N. Paddington, C.U.), Retail Business; Alex Richardson (Gravesend, C.U.), editorial staff of *Engineering*; A. K. Rodger (Rutherglen, C.L.), Provost of Rutherglen; W. S. Royce (Holland-with-Boston, Labour); and A. E. Waterson (Kettering, Labour).

HAVING obtained their Select Committee, our critics are not altogether satisfied if we may judge by one of the most flamboyant, the *Sunday Express*, which thus disburdens itself:—

> Although the telephone fiasco is saddening and maddening, it is also droll, for it reveals the innocent impotence of the entire business world in the coils of the bureaucratic boa-constrictor. All the meetings, speeches, protests, deputations, and whirlwinds of public anger were wasted. The permanent officials who hide behind Mr. Illingworth laughed at the agitation and neatly side-stepped its body punches and knock-out blows. The debate was a roaring farce, and public opinion was impudently and cynically tricked out of its prey. The bureaucrats knew that they could rely upon the timid lethargy of a tame House of Commons which is so utterly out of touch with its constituents that it did not even go to a division. The telephone ramp has now gone through, and the select committee, after solemnly sitting for months, will only add another futile report to those that are mouldering in the pigone-holes of bureaucracy.

And yet the whirlwinds were well stage-managed!

THE *Daily Mail*, turning aside awhile from its scrutiny of the meals consumed by the German delegates when in London, returned to the telephone question on March 11 with the headline: "Telephone users must wake up." "The forthcoming enquiry will be the 'Battle of the Marne' of the telephone business of Great Britain," it says. "It will decide whether the vested interests and dull prejudices of our autocratic bureaucracy shall prevail against business sense, freedom and progress." Eliminate the words "of our autocratic bureaucracy," and we agree. The position could not be more succinctly stated.

THE Ministry of Posts and Telegraphs for Jugo-Slavia has decided that the rates for telegrams shall be increased from 10 (about 2*d*.) to 20 paras per word. The minimum charge is fixed at 2 dinars (1 dinar=a franc or about 9½*d*., normal exchange).

Subscriptions for telephones at Belgrade, Sarajevo, Zagreb, Ljubljana, and other cities, from July 1, 1920, are:—(*a*) For hotels, cafes, industrial plants, factories, commercial firms, commercial agencies, law offices, stores, and all places serving for public re-unions, 500 dinars per year (£19 17*s*.). (*b*) For newspaper editorial rooms, private apartments, state and official offices, 300 dinars per year (£11 18*s*.). (*c*) For telephones installed in residences of public functionaries, 200 dinars per year (£7 19*s*.)

ACCORDING to the *Morning Post*, a bill will shortly be introduced in the French Chamber sanctioning the abolition of the flat rate charge for telephone service in Paris and other large cities, and the introduction of new rates. The charge for areas with over 10,000 lines will be 550 francs (£21 16*s*.) including 1,000 free calls.

THIS portends, of course, another Telephone Ramp—to use the language of most of our contemporaries. From Liverpool to Ljubljana, from Vienna to Vexjo, from Paris to Potsdam, from Rotterdam to Ramsbottom, it is the same story, and the same moral might be pointed in each case. And then, as we write this, we learn from the *Daily Telegraph* that by the increase of the rates by 28 per cent. from April 1, "considerable disgust has been aroused in New York!"

A SAPIENT correspondent of a Newcastle journal says:—"The National Telephone Co.'s staff in 1905, 19,050; Post Office telephone staff in 1920, 44,500. Think of it! It takes 44,500 Post Office clerks to do the work that 19,050 National clerks did, and did better." There were 427,000 subscribers' stations in 1905, and 990,000 in 1920. Does the writer of the letter really think that to serve 427,000 involves only the same work as to serve 990,000? The proportion of staff to stations is almost exactly the same in the two periods.

WE learn from the *Telegraph and Telephone Age* there are twenty-one telegraph companies operating in the United States with a total pole line of 241,012 miles and 1,888,793 miles of wire. More than 155,000,000 messages are transmitted a year. For the convenience of customers 28,965 offices are scattered over the country. A total of 39,600 employees receive salaries amounting to nearly $40,000,000 annually.

We learn from the *Electrical Review* that the Dominion of Canada acquired at the beginning of this year the telegraphic systems of the Great North Western, the Grand Trunk, Grand Trunk Pacific, Canadian Northern, Inter-Colonial Railway and Commercial Companies, in addition to a certain number of smaller companies. These form a State telegraphic system which will be one of the largest in existence. The United States probably remains the only country with a large telegraphic development where the system is under private control.

SIR ANDREW OGILVIE, the late Second Secretary, gave a lecture on March 4 to the Society of Civil Servants on "The Administration of State Telephones." The Postmaster-General took the chair, and we noticed a representative gathering of the chief officials of the Post Office amongst the audience.

Probably no greater authority on the subject than Sir Andrew, with his long administrative experience of State Telephones, could have been selected. He explained the difficulties the Post Office had had to contend with, its achievements during the War, and its redoubled energies since. He was easily able to demonstrate that the rise in telephone charges was due to the enormous increase in costs.

CORRESPONDENCE.

WIRELESS TELEPHONY.

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

SIR,—I note that in the review on Mr. J. Poole's new work on Telegraphy, Telephony and Wireless, the reviewer casts doubt on the quantity of speech transmitted by the radio-telephonic apparatus. Has the reviewer heard the speech transmitted by the apparatus in use at Chelmsford?

Some few months since information was received at Preston, Lancs., that on a certain Sunday at 11 a.m. speech would be commenced from Chelmsford to a station in Sweden. We got our apparatus in order and tested everything thoroughly in readiness for the event. Ship stations could be heard well on 300 metre wave lengths. These were varied for different stations of known length. Liverpool came in with a bark resembling that of a retriever dog and then we waited until we got the well-known "Hullo." It may not have been a correct expression but there could be no doubt of the volume and distinctness. As a telephone man with over 25 years' experience of trunk working I say that I have never heard a message over a trunk circuit 200 miles in length more clearly defined than on that occasion. We were working with an aerial under the scheduled length and with a change-over switch, bringing in as an alternative an inside aerial of 100 yards of ordinary bell wire wound loosely on a tripod suspended from the ceiling about 10 feet from the floor and heard with very little deterioration when compared with the outside aerial.

The apparatus was almost entirely, home-made, with the exception of the valves and receivers. The results with such crude equipment led me to conclude that there was a future for this method and I am anxiously awaiting the results of experiments with the introduction of those thermionic valves into the existing trunk circuits which I understand is in progress. From my experience of these valves I am led to expect much improvement in the trunk service of the Department at very little increased cost.

S. J. PHARO,
Late Chairman Wireless Section Preston Scientific Society.
Preston, Feb. 21, 1921.

STUDIES IN WHITLEYISM.*

BY F. C. COOK (*Accountant General's Department*).

BEFORE we enter seriously upon our studies this evening, will you bear with me while I make a few preliminary observations. We must, I think, seek to build up some kind of background if we are to see more fully, at a later stage, the central features of the picture. We are dealing with an institution, an organisation having, by successive decrees of Parliament, a larger scope, and necessarily greater complexity, than individual enterprises; the statutes are the work chiefly of trained lawyers. The British Civil Service has been silent; its very silence and power have evoked the interest of foreign Governments. Doubtless the public services of other countries have influenced the frame-work of our own, but the Civil Service Commissioners are alone able to disclose the changes made as the result of external investigations. We will take note of the principle of nomination which so long obtained before it was succeeded by the "open door." "Gentlemen" must henceforth reveal that they possessed the intellectual qualifications scheduled by the Commissioners, and would use them in the best interests of public business. Possibly for a time some gentlemen continued to begin the real work of the day when they left their offices; a change was, however, inevitable. The name of Charles Lamb is beloved; but we cannot place his name on a level with Roosevelt as a public official (taking an American example to avoid difficulty).

The principle of the "open door" of competition (though Ruskin deplored the method) carried with it the germ of division of labour. Adam Smith's utilitarian ideas may or may not have seized the minds of those whose statesmanship was unfolded in expansive Civil Service schemes, but gradually there emerged the plan of Administrative Grades (and ratios of appointments), grades whose intellectual inspiration was almost entirely derived from Oxford, Cambridge, or St. Andrews, and whose spiritual leader was Jowett of Balliol. Departmental grades for specialised appointments, and "Treasury" grades, for duties more or less common to the whole Service. I hope no one will imagine I speak ungraciously of the older Universities: those homes of learning have touched one's deepest feelings, and though some criticise freely, one can always mention Cecil Rhodes as a great lover of Oxford. To return to our review—each group had an environment, a life of its own. The Civil Service was one, but after men met in the halls of examination they appeared to drift apart, and, as individuals, to lose their identity in the immensity of their departments. The Commissioners removed their names from the successful lists; not until long years had elapsed did the names of any individuals appear in the Press—even the Civil Service Press—unless an Officer was placed in the front rank of public servants at the outset of his career.

While the majority of public departments developed on normal lines, Post Office administration rapidly spread in all directions; its staff was chiefly departmental; it had groups scattered throughout the United Kingdom and some districts grew more rapidly than others. The open door into this special service was more or less accepted for many years, but difficulties about the blind alley led to a policy of shutting the doors, or some of them, sharply at about the age of 14-15.

The Committee on National expenditure tell us the Statesmen at the Treasury strove even during the War to control all the duties of public departments with a staff of 33, and the Civil Service Cabinet would have limited its membership to that number had not pressure been brought to bear upon it.

The growing army of Post Office servants led to the formation of a more or less collective opinion which expressed itself at times in a demand for departmental or parliamentary enquiries. Outside this sphere of personnel the Civil Service as a whole, remained undisturbed except in 1876, 1890 and 1912-14. Only in these years had any comprehensive investigations been carried out. The Orders in Council did provide for periodical enquiries, but it did not follow that such should be invariably general re-organisations. The initiative came, ordinarily, from each department according to the expansion of business.

The creation of new departments led to subsidiary policies. The new departments took advantage of a side track method of finding a legitimate opening for public school boys who were unable, for one reason or another, to pass on to the Universities, *i.e.*, Oxford and Cambridge, not the new Universities, because their men had practically no chance of securing a place in the higher examinations.

Two other noteworthy expressions must have their place, viz., (1) the "Model Employer"—the exact date of its introduction I have not traced—but some years ago I sought to tabulate the factors of the environment of the public servant as compared with external corporations, and came to the conclusion there was no doubt that the Civil Service did lead the way in regard to favourable conditions; and it would be an interesting study to see what leeway has been made up in commercial circles during the past, shall we say, 10 or 15 years. (2) "Scientific Organisation" was used infrequently respecting the public service; in fact only within the last three or four years has it had a prominent place in an official report: it is now much to the front.

Having found a place for the foregoing features one is led to ask two or three questions about the widest aspects of our subject. Was there anything to mar harmonious development? Why should there be? Was anything unexpressed? Was there any group consciousness? If so, was it on healthy lines? Was it for progress; for the efficiency of the individual, of the group, of the whole public service? Was the spirit of Science—with a capital "S"—exercising a leaven throughout the country. Let us simply ascribe it to a consciousness of environment, and leave it at that.

Here we can conveniently make contact with the economic philosophy of a North Country leader of business, who is also a prominent Member of Parliament. The Right Hon. J. H. Whitley, Chairman of Committees and Deputy Speaker, voiced an idea for the benefit of industrial undertakings, in the interests of all concerned; those who were the captains of industry, and those whose co-operation (as a class) was required for the fulfilment of contracts. Contracts were increasing in size, involved ransacking the earth's surface to find raw materials, and required the conveyance of machinery to distant parts of the world, the War showing that greater enterprises were possible than in pre-war days.

To me it is unfortunate that the Whitley idea should have obtained publicity under the ægis of grievances. Many "Wants," to employ the word of the political economist, are known, but wants are not necessarily grievances; the scientist is ever seeking to meet "wants." No reflections will be entered upon regarding grievances. The fact is stated, and if such was warranted let it suffice to be recorded that grievances existed because the highest officers had so many duties to perform that some aspects of organisation, relating to the personnel, were unprovided for in the establishment of public departments.

When Whitleyism had become an acknowledged fact in the Administrative and Legal Departments of the Civil Service, following its inauguration on the July 3, 1919, when the Chairman and Vice-Chairman of the National Whitley Council urged every one, irrespective of rank and title, to become a member of an "association"—City Guilds had been in existence for centuries and possess historic halls for their places of gathering—the effect of the complete acceptance of group consciousness was bound to extend to the more responsible members of the public service, who would necessarily, though not in hostility to one another, have a dual function to perform, sometimes to sit on the official side, and sometimes on the staff side, or be represented by a lower Staff nominee. I see no objection to the arrangement. The highest individuals in the legal, medical and engineering world find no difficulty in belonging to incorporated societies.

The pace was forced by rapidly issued reports on public departments, by the insertion of these documents of "scientific organisation," by the co-ordinated report of the Machinery of Government, by the immediate action of the Treasury in setting up a comprehensive system of Establishment Officers (and, by the way, establishment matters were regarded for years more or less as domestic, and less weighty than the conduct of normal business), and by an entirely new view of personnel, recognised henceforth not as classes, grades, numbers and scales of pay, but as individuals contributing their personal share to the well-being of the whole fabric.

What should be the shape of this post-war, externally introduced idea of Whitleyism? How could it be fitted in when there was on the official side doubt as to its desirability? Surely Whitleyism should not have in its vanguard grievances, especially as the very mention of such would, or might, affect the feelings of a vast number so far undisturbed.

The minds that were set to explore this wonderful conception of the Right Hon. J. H. Whitley became absorbed in their work, and the Service watched the collaboration with fervent interest. The Official side had all the historical past; the staff concentrated upon the new conditions which the victory in the great war had brought within the range of possibility. The Civil Service had not failed the nation, and through their representatives they placed in the forefront of their recommendations the continued efficiency and further development of the public service. The report did, however, create an atmosphere, a living interest, which was not present in previous re-organisation proposals. Moreover, the report was at once the property of the whole Civil Service, the decision arrived at having an importance, actual or implied, to every individual, from the highest to the lowest, and by whatever classification he might be known. Though the analogy cannot be sustained, the framing of the American Constitution by many men with conflicting interests (and after all not in the behalf of a large population—the total was about 2½ millions) was a prodigious and difficult task (*vide* the Federalist of those days) and the reconstitution of the British Civil Service with its hundred and one associations, with its scientific, legal, engineering and medical groups, without mentioning the educational groups, was by no means an ignoble task, especially as we are conscious of the beginnings of further developments by the appointment of an International Civil Service under the authority of the League of Nations.

In the midst of their negotiations the national representatives came up against a difficulty—at least so far as the Civil Service was concerned—and decided to press it to a conclusion. They declared for the attitude that the employed should have the right to choose as their representatives delegates who were engaged wholly in the interests of the public servant and beyond the control of the Administrative authorities, and outside the jurisdiction of the House of Commons. Except when these delegates were taking part in a Conference with the official representatives of the State they would be employed in a private building, perhaps far removed from the Department where their members were working. The case of the Staff could doubtless be prepared better on the lines of advice being sought from counsel, but the extent to which this external assistance can normally be granted, would appear to be that of grievances or the presentation of the reasoned views of the staff respecting the conditions of their service, and similar considerations. The idea that officials outside should come more closely, as time passed, into the machinery of organisation is surely beyond the limit of scientific organisation. The idea has, however, apparently found acceptance elsewhere, and entrance

*Paper read before the London Telephone and Telegraph Society.

Digitized by Google

into the public service may eventually have further developments not unlike the control of departments, devolving upon ministers who are connected with the political bodies of the House of Commons. The recent appointment of a well-known Labour leader to the public service is a case in point. The Administrative and Legal Departments having, under the first Reconstructive Report (doubtless to be followed by other schemes), provided the approved methods of entry into the Civil Service, the ultimate expectancy would be that the service itself should be able to grapple with all its own difficulties.

The Right Hon. J. H. Whitley admitted, recently, his scheme had within it the idea that collaboration between the representatives of groups and those who held authority would lead to the discovery of latent productive power. Consequently, the more developed the joint principle was realised the greater would be the gain to the organisation. The joint working would also resolve itself into equality of contact with the responsible authorities by each representative whatever might be his status. This was conceded in the composition of the National Whitley Council.

The ideal relations between Employer and Employed, particularly if the delegates are drawn from every group (the doors of entry into the Civil Service being many, admit of various types of representatives) predestines closer and closer co-operation of all concerned, until the whole should move harmoniously towards the same objective, the same levels of thought, the same understanding of public business.

The full significance of the permeation of the Civil Service by Whitleyism is scarcely discernible; it is a new force. On the face of it the first Reconstruction Report contains much that was embodied in the views expressed by those who drew up the recommendations of the Royal Commission in 1912-14: fundamentally the report is not the same, one reason being that no external business organisers had any part in the negotiations. Much of the nomenclature and many details are differently described; but a study of the re-organisation suggests familiarity with earlier data. Arising from the Agreement there is the possibility of truer comparative conceptions of the technical, scientific professional groups, affording a vision of the whole Civil Service, something beyond the impression created by a study of the Regulations of the Civil Service Commissioners, and the annual reports of that body.

The National Whitley Council completed its first report, and immediately proceeded to take up the next stages of its investigations. Unlike references to Special Committees, prescribed, limited, the Council has apparently power to consider any questions, temporary or permanent, affecting the Service. When its members began to turn their attention to other subjects the Departmental and "Office" Councils were set up, and new bodies of individuals commenced work on the divisional aspects of the Whitley idea.

Ideas of parochialism and even provincialism receded, and national opinion, or as at the first remarked, group consciousness generally, took their place. Individuals, who had spent years of their career in obscure rooms, in subground floors, in old buildings, awakened to a new interest in official life, and the enthusiasm of the delegates spread to them. Such a document as Scientific Business Management issued by the Ministry of Reconstruction added to the new impulse; it recommended that senior Officers and higher than these should encourage the staff by occasional tours of the Office; other useful suggestions were included in the recommendations.

The Whitley idea found favour beyond the shores of Great Britain, and the reports from the Dominions and Colonies indicate that Civil Servants of the Empire are watching developments in the Homeland.

A central feature of the scheme is *group* function, and *individual* growth. Each group must contribute to the organisation its quota, expressed in hours if you will, but certainly in intensity and standard. We are frequently told that the 'Varsity man subscribes to the plan that he shall give *six* hours' hard reading daily, apart from auxiliary preparation. The Imperial College of Science, understood to be one of the most go-ahead institutions, adheres to this scheme. The problem is how to arrange that each group shall fulfil its own functions, not for a period of three or four years, but for life. But the higher the rank the more variable must be the duration of public duty in times of emergency. I must pass on, however, to the more important function of training—due preparation for the enlarging duties of the public servant where the individual has not obtained expert experience before admittance to the Service. For the first time it has been placed on record, partly interpreted, for the most part uninterpreted, that Administrative functions are specialised, professional, and quasi-professional.

Even the Administrative candidates must submit themselves to a special preparation for their future responsibilities. They are given, on entry, the status of a Cadet Corps, and the recent establishment of an Army College of Administration affords at least an illustration of the changes taking place in the highest circles, and the Cadets, like the training grade of the Executive groups, will presumably have a specially drawn up scheme.

It is hardly appropriate for me to conjecture what either the Administrative or Executive scheme will be. Conceivably, groups who have had specialised courses, theoretical and applied, will not be outside forms of preparation for the particular divisions of public service to which they are assigned. The National Whitley Council has promised to give proper attention to technical, scientific, and other groups, through the Agency of Grade Committees (the precise arrangement will be referred to shortly). The fact that every group is working within the region of Public Administration, each member of the Civil Service must take cognizance, varying much in degree, of three central principles which operate everywhere, viz., Administrative Law, Finance, and organisation in its broadest aspects. The change in the syllabus of the Examination for the Administrative Grade, or rather the complete liberty of choice permitted provided that a full university Honours Course has been followed, has led critics of the scheme to favour in the days to come the London B.Sc. (Econ) Course, which will not only provide the desired mental training before entry into the Public Service, but go a long way to enable the student to have Administrative preparation (and doubtless the Executive will have similar privileges) in advance of actual performance of public duty.

In this connexion I have seen it advocated in an official report that due preparation for a public career may include, so useful in these days when the League of Nations calls to all to work together for the peace of the World, residence abroad for comparative studies and personal contact with Administrations of other Countries. This is in harmony with Mr. Whitley's objective of conciliation, because the Civil Services of civilised states may mean much to conciliation between one another, and a common interest in the welfare of their citizens.

Lord Eustace Percy mentions this subject over and over again in his work on the "Responsibilities of the League of Nations."

Twenty years ago an eminent scientist pointed out that functions of Administration required a specially trained staff, a new professional class, and whatever be the precise scope of the professional training the outcome must be the possession of an international outlook, a cosmopolitan spirit with freedom of thought, and a type of character referred to in the Royal Commissioners' Report of 1914, viz., resourcefulness, judgment, common sense, readiness.

In 1921 we have advanced a further stage, and added to the conception of public business the commercial idea, or partially so, of business organisation. Sir Herbert Morgan for one, is not anxious that the public servant should become a business man, but granted that the training, within the Service as well as outside, is on right lines, I urge that the Civil Service should be able to produce men embodying all that is best in business organisation, and that on a large scale; I take it the training will lead to business excellence whatever the past may have wanted in this respect; the introduction of commercial balance sheets side by side with the other requirements of administration substantiates the view. But business organisation being a subject coming within the syllabus of economics and commerce should acquire a meaning equally applicable to Public Administration, or "Scientific Administration" (to use the phrase of a well-known Captain of Industry), of private enterprise, and afford a common standard of judgment.

The application of business principles to the Civil Service, to Administration, must not, however, take precedence of or stand in wrong relations with the business: while the delegates of Whitley Associations were, and continue to be, engaged in intermittent negotiations the government of the Country proceeds. To mention only the five Peace Treaties, India, Trade, Education, the Communications of the Empire (compare the recent deputations to the Postmaster-General and his replies)—all these, and these samples from the interests of some sixty departments—seem to be great, fill the imagination when viewed in comparison with the efforts to invent a formula to fix the pay of a group. On the other hand, the perfect equipment, training, and strength of will of the units of the Army and Navy produced the victory of the War, but perfect organisation included instant readiness to take from stock pairs of boot laces, without which the men could not march. The two conceptions have a mutual bearing. And for great affairs of State, when one has reached the heart of them, the brilliant idea (the Whitley scheme specifically mentions ideas) of an unknown Civil Servant may materially contribute to the solution of an entanglement, apparently insoluble.

It may be that some day, and I am not sure that the milestone has not already been passed, the scientific mind will turn its attention to the *practice of business*, and the so-called "practical" mind will be matched with and outclassed by the resistless energy and pertinacity of the scientist. The men who have wrested the secrets of light, sound, heat, the dust of the earth, the constituents of the air, will not be daunted by the greatness of world business organisations. Here I am thinking of the pure scientist.

Sooner or later the public service will feel the influence of these scientific movements—so enormously strengthened during the War—and I may add the Whitley scheme appears to contemplate the absorption of the new forces—the outcome of which must mean changes fundamental in nature, and some of such a constitutional character that the relations of the centre to the circumstance, to the outlying parts of the area under survey and control, will perhaps be a microcosm of what is taking place in the larger world of affairs and particularly the British Empire. The threefold Whitley plan of National, Departmental, and Office Councils contains within it possibilities of forces acting and reacting one upon the other, and what it will mean ten years hence no man can tell.

When Professor Marshall sent forth his monumental book on principles of economics the scientific spirit in other than the world of natural science was immediately revealed, but its due importance was not, except in specialised circles of the Civil Service, fully realised nor its intrusion warmly welcomed by those whose outlook was more or less entirely literary. But this is not so now.

The title of my paper forbids the exploration of the functions of the Civil Service apart from the aspect of Whitleyism, and the annexation of the Whitley scheme by Administration. Those who desire to pursue the subject and see how many new responsibilities have fallen upon the shoulders of officers of the State, should search Hansard about the end of the Sessions of Parliament for so short a period as, say, the last four years, tabulate the regulations for annulling, superseding the powers created by the War, and take out from those records of public affairs the new statutes of first class

Digitized by Google

importance. The Irish Act of 1920 alone will cause much work in Administrative and other circles.

The apprehension of the whole as well as its parts, like the survey of a leading newspaper, with its Reparation Agreement at Paris on Jan. 28 on one page, and parochial matter on another, has, in these days to be accompanied by three mental attitudes—intense inventiveness to reduce expense, great concentration to produce rapid accomplishment to please the public, and earnest consideration of plans to dovetail into, *e.g.*, the P.O. system, still other activities. I think the members of this Society have had experience, not once only, but many times, of the necessity for taking up all three attitudes at one and the same time.

The chosen delegates have had, in addition to these varied intellectual operations, almost unceasing work after hours to study the basic problems of reconstruction; studies which, in many instances, were entirely new and unexplored, but which were performed with, I submit, dignity and fidelity to the staff.

The decisions of the Departmental Whitley Councils are less simple. They are without prejudice to:—

(*a*) the overriding authority of Parliament and the responsibility of the Head of the Department as such;
(*b*) the responsibility of the staff side to its constituent bodies;
(*c*) the authority of the National Council as the only Whitley Joint Body competent to deal with general questions.

Agreements are to reach the proper executive authority without delay; but with the infinite number of ideas conceived by an awakened Civil Service, the formation of generic principles would appear to be a difficult procedure, and when the principles or would-be principles, have been set down in writing the parties cannot invariably agree, the more so when a decision means an immediate outlay of public money. The ideas may have been novel to both sides, and time is needed to see the true bearing of a question to the Civil Service Administrative law already passed.

Where the problem remains unsolved, or, more exactly, disagreement is the result of negotiations, reference may be made to the Civil Service Arbitration Board, and their adjudication sought. I gather that the constitution of the Court rests on the same foundations as an ordinary Court of Arbitration. This course fits in with English methods of selecting an umpire, but it requires the admission that both sides will abide by the judgment of the Court, unless fresh evidence can be produced to warrant the reconstruction of a case which has so far been negatived. Already the Court of Arbitration has made many awards.

We have now had under observation the main lines of movement of the new Whitley scheme; we have watched the delegates at work; we have seen their intensity of thought, their sincerity, the spread of the influence of the idea everywhere; while every part of the machinery, every condition of the "Group," of the individual, is preparing the new régime to supersede the Victorian régime, and all is being transformed by "Business as usual," or "*not* as usual" as the Bishop of London once said.

By stages Whitleyism tends to a complete confederation. The Civil Service is one; Whitleyism seems destined to produce unity of group consciousness; a kind of Civil Service parliament, with specially selected nominees of Associations.

Should the idea of a Civil Service Parliament be realised the representatives of so many thousands of men (and their families) and the single women, will have, besides the performance of their public duties which do not tend to become less in importance, a responsibility never known to a public servant—the joint responsibility of fulfilling a public duty and a kind of parliamentary duty after official hours—and wise leadership, great ability and impartiality will be essentials of their character. Of course, many men in public life carry varied responsibilities upon their shoulders. Was not Lord Rhondda director of some thirty business enterprises?—but so far the Civil Servant has not had a great sphere of activity and high responsibility outside the duties of his Office.

But will Whitleyism be a permanent factor? Will it spend its force? Can we go back? What will be the fashion of the new regime? These, and kindred questions presented themselves for answer, and while they remained in suspense it has been announced that the final report of the Committee on the organisation of the Civil Service was received by the National Council on Friday, Jan. 28, the details of which will probably have been discussed before this paper is read before the Society. The Council have agreed to set up the following Committees (1) A standing Committee to examine and report from time to time on any question of general principle not covered by the recommendations of the interim report of the Re-organisation Committee, which may emerge in the course of applying the revised scheme of re-organisation throughout the Civil Service. (2) A series of Committees to consider classes of professional, technical and scientific Civil Servants—I alluded to them at the beginning of the address. (3) A special Committee to elucidate the conditions and the consequence of those conditions, which constitutionally underlie the application of the Whitley procedure to the Civil Service. And further the National Staff side issued to the press on the 1st instant, their decision to assist the staff sides of Departmental Whitley Councils to correlate their aims and activities, and, for the co-ordination of the work and policy of the Staff sides of the Departmental Councils with those of the National Staff side. The complete scheme which is of far reaching importance is as follows:—

(*a*) Regular meetings to be convened by the National Staff side; (1) Meetings of representatives of the Staff Sides of Departmental Councils, and (2) meetings of secretaries of the Staff Sides of Departmental Councils. The members of the National Staff Side will participate in the meetings, and the chairman or vice-chairman will preside.
(*b*) The secretarial work involved, staff and accommodation to be provided by the National Staff Side. The National Staff Side to appoint an additional officer to take charge of the scheme under the National Staff Side's direction.
(*c*) The existing means of interchange of information to be improved by the receipt of full records of the proceedings of Departmental Whitley Councils; and a circular to be issued once a month containing extracts from those proceedings, together with such information as may be available concerning the work of the National Council or otherwise of general interest.
(*d*) The Staff Side of the National Council to meet the expenses of the scheme, other than subsistence and travelling expenses.

The decisions and arrangements do not preclude the idea of possible complete confederation of the hundred and one organisations, to be followed by the continued expression of external, and therefore unfettered opinion, as distinguished from the internal co-operation between the official and staff sides as set forth in the several constitutions. But the responsibility of the directive control will correspondingly increase, and the rights of minorities must be honourably safeguarded.

There is one noteworthy omission from the "objects" and "functions" of the Whitley Scheme. Normally the subject would not be stated between parties who introduced "grievances" into their weighty document. I mean economy. The expression efficiency is in the text, and all round efficiency must produce economy—and increasing economy. The words of Lord Weir, spoken on Jan. 28 last, are helpful here. He said:—

"True industrial prosperity can only exist when the product is technically of the very highest character, when that product is produced by the highest development of process and method, wherein labour is utilised according to the grade of its skill and capacity and remunerated on a scale commensurate with a very high standard of living, and on the other hand, with a price for the product which gives a reasonable return to capital, and which enables the purchaser to operate that product on an economic basis, and finally, a system of taxation which has regard to the economic possibilities of the industry, and permits of the carrying on of a reasonable amount of social reform. That is my definition of efficiency."

* * * *

"We have got to get down costs. . . . Let us concentrate at first on process, method and technique. Let us rid our industrial costs of the inefficiencies and disabilities which are included in these costs. They hold much greater possibilities than any mere wages reduction holds, and we are not meeting our responsibilities as captains of industry until we have adequately tackled what I may call the inanimate end of cost production."

The expression economy is sometimes loosely employed by the practical mind, whereas the quotations which I have just read convey a much more comprehensive meaning. There is a danger that the practical economist may be prejudiced against research. He may enter the research students' laboratory, and unappreciative of the experiments in hand, of the delicate instruments around, of the patience required, and of the ultimate possibilities of the work, may regard the "expense" as representing something unremunerative, and a charge not to be incurred in his own organisation. Such an individual does not know the value of the Bessimer discovery, nor for example, the construction of such an instrument as a saccharimeter. As this audience is fully aware, the discoveries in the world of radio-telegraphy are so numerous, and the struggle to bring pure science into the service of man so unfalteringly pursued that radio-telegraphy must shortly become—and universally—an auxiliary to land and submarine telegraphy.

Here then is the problem of economy. On the one hand the detached idea of the discontinuance of an old practice to reduce cost—and rightly so—on the other the constant study of every feature of business in relation to the objective of the organisation, and the encouragement given to the research department, notwithstanding the outlay, provided the department is in the care of the highest type of trained expert.

Two extracts from the report of the Privy Council for Scientific and Industrial Research, 1919-20, may not be out of place:—

The Encouragement of Individual Research Workers.

In the light of what has been said we need make no apology for placing this subject in the forefront of our remarks. Endless emphasis has been laid both in this country and abroad upon the necessity of organisation in the application of science both to the needs of industry and to the national administration. One of the most obvious lessons of the war for peoples like our own, whose organisation is weak, was that rapid progress in the use of science with a view to defence or to increased production is not to be expected in any country which depends simply upon the undirected genius of its people. "The extraordinary rapidity with which scientific developments were made in the war was unquestionably due first to the forming of highly competent research groups and second to the establishment of effective channels for the co-operation of these groups."

The Radio Research Board.

The problems to be attacked by systematic research in the whole field of wireless telegraphy at present appear to be divided into four main groups, viz., those concerning what may be briefly described as propagation of wireless

Digitized by Google

waves, atmospherics, directional wireless, and thermionic valves respectively. For each of these branches of investigation a sub-committee has been formed consisting of men well versed in the theoretical and practical aspects of the subject, who will advise the Board on the research work needed and analyse the results obtained. It is hoped that this work will be carried out not only in the Government establishments but also in universities and other institutions, the authorities concerned having in many cases stated their willingness to co-operate with the Board so far as their recources allow. The Department will be in a position to supply a certain amount of wireless telegraphy apparatus to investigators who may be appointed to undertake work for the Board. . . . The primary object of the Radio Research Board and its sub-committees is thus to provide a convenient channel by which the results of scientific research undertaken on a basis of pure physics at universities and similar institutions may be made readily accessible for application to the experiments in designing apparatus which could be carried out mainly in the Wireless laboratories of the Government Departments interested."

The responsibility of adopting ideas, applying new methods, incurring expense for research must, of course, rest with the organisers, but the point I wish to press is the difference between "practical" economy simply, and the slower but certain effect of scientific work ensuring much larger reductions in "Cost."

Conciliation is another feature, the core of Whitleyism. It presents difficulties to my mind; it seems to force the admission that there has been antagonism, that the greater percentage on the Staff Side has at least dwelt in "unfriendly relations," to use a term of diplomacy; that the spirit of adventure has not existed, a common objective attractive to each and all has not appeared on the horizon. Perhaps Mr. Whitley, who knows the House of Commons so well, attached a different meaning to his plan of conciliation; he may have had the impression created by constant debates conducted by "Gentlemen," or controlled by rules which compelled gentlemanly demeanour, that the two sides of his Councils would necessarily debate the ideas submitted on the agenda for the day, and that the conciliation should represent common approval of principles or ideas, independent of any suggestion that the two parties themselves were in open hostility, were wanting in goodwill. My recollections of the proceedings of the National Whitley Council pointed to most heated discussions at the first, but when all had settled down to their work the conferences were most amicably conducted.

Agreement by the present generation of Civil Servants was the first business of the National Council. The Councillors did not stop there; when they signed their report they had provided for the future—for those who should pass in under the revised schemes of Education prepared by Mr. Fisher. They contemplated re-opening the former competitive system, subject possibly to a new selective—possibly a psychological method. This has been overshadowed by the imperative need to help those who risked all in the interests of the Nation, and part of the reconstruction, the development of Whitleyism the efficiency mentioned by Lord Weir, must include conjoint work between the existing Civil Service and those who have not had the atmosphere of the Service about them from their youth, perhaps a fortunate circumstance, seeing that we are concerned with post-war considerations, not pre-war.

Looking back on the negotiations, the discussions, the consultations, some critics appear to be depressed. Many men are rather tired of the problems which have come up for re-study and solution. Possibly the newly imposed duty on the official side has added to responsibilities already sufficient, and overstrain has been the outcome. By degrees, however, I believe that collaboration will yield lasting and good results, and both sides will appreciate points of view which were not attractive a few years ago. The "Employer" will be among the employed. The "employed" will have developed a confidence and freedom to enable him to take on higher functions, as the Whitley report anticipates. Gradually the "paper" constitutions will be lost in the realisation of the factors intended to be usual in public life. We hope it may be so. Better that the Service hope than doubt. Better that a newly organised Civil Service start afresh, and whatever may be the losses, from the passing of the old régime, there will be in the new régime much that will be a distinct advance to the personnel who will produce better results. Some will agree that Whitleyism has, on the other hand, brightened the present and the future by what it has already conceded to the Staff. Agreed that the Service has benefited like other groups of the community: I feel my special duty is to consider the Whitley idea from its wider standpoints, and show that it has negatives and positives, and that while the career of the Civil Service is more clearly defined, that career is also to be accompanied by the new psychology of Mr. John Lee.

But will the career be tinged and inspired throughout by the loftiness of the appeal to the imagination, public duty and service? Will there be that perfectness of training that the servant will be consolidated in his public character, and his environment sustain him in a high degree of efficiency? Will there be a common standard of leadership, and I lay great stress on leadership, constantly realised, drawing towards higher attainments? Will every man's gifts or peculiar bent find its proper sphere? Will the Civil Service Parliament have a place in the interests of the public servant after he is released from his daily duties? Or will he add to his services after hours other voluntary civic duties recommended by earnest men? One of Mr. Whitley's desires (so he told me when we talked with him about his schemes) is to compel employer and employed to meet other than in the office; true progress, he thinks, will be made when men on either side do not live in a narrow world, like many Victorians, however successful the highest in rank may have been, but enter into the best of the social life of the times. The combination of interests will be for the welfare of all. The expression of this opinion in no wise detracts from the views referred to earlier.

The gradual change in the organisation of public duties will ensure that proper functions will be allotted to responsible Officers, the highest Officers, and it will not be so frequently remarked that whereas one part of a Department is overborne with excessive duties, another part is privileged to enjoy comparative quiet. Division of labour, labour-saving devices, and a host of other productions of the Whitley Scheme will permit the great machinery of public administration to adjust itself readily to the demands of the moment. This happily accomplished, the life and interest of the public servant will be something different from the past, will almost unconsciously lead to much more business being conducted than at present by the same group of individuals, and withal the physical strength and intellectual power remain, because suitable environment will be ensured under the new conjoint action of Whitleyism. I cannot enter into the material reward for sustained effort. Humanity is wonderful, mysterious—life; and Whitleyism, the new force operating in the Civil Service should have a quickening impulse to life in public departments, but when all is said the influence of reward as well as the fulfilment of duty must be a factor in the new régime, and if that new régime is to call forth all that is best in a man throughout his career.

I fear I have sketched this paper primarily from the standpoint of the Administrative aspects of Whitleyism. Our members are more intimately concerned with Departmental Councils—Engineering, Technical, etc, but the ideas I have expressed are, I think, to be found more or less in all Whitley Constitution.

We have a scheme proposed for the industrial world (so called), applied to an old régime, a great institution, an institution which in spite of criticism, has made the Government of the country to be admired by other great states—a scheme introduced in the midst of conflicting thoughts, of a deeply moved nation, of the after effects of a crime against humanity, of the consciousness of a generation in the space of six years, of almost daily potions of deflation and inflation—a scheme launched in an era when the scientific spirit is everywhere, when the school and university curricula are undergoing rapid change, when many ex-service men have returned to find no opening for times of peace—and lastly, but not least, when the Treasury has added to its staff and appointed its representatives in every department to regulate the working of the new idea. What it will produce I cannot say.

I have but attempted to place on record some of the impressions which I have received from the study of Whitleyism since its inception. I am conscious I have not presented them worthily to the honoure l Telegraph and Telephone Society. The preparation of the address has, moreover, been subject to many interruptions, many calls upon one's time to attend to matters arising out of Whitley problems. At the moment there are infinite details of the establishment of the new machinery which compelled a process of selection—and not an easy one—of material. The one all-absorbing, outstanding question to me has been the place of the Civil Service in the eyes of all other Administrations. Criticised it may be, faults found here and there, slow emergence into the full light of day admitted, still I venture to submit that on the whole, whether retarded in its true development by considerations beyond the control of the Service, whether the right professional spirit has or has not been always exhibited, whether professional training calculated to meet the changeful conditions of public affairs, has been found wanting, whether the Civil Service has preferred to live, or necessarily has lived, unknown by the world at large, but now has come forward ready to mingle in the midst of national interests. I submit again, the Service under Whitleyism has declared in its Constitution to each and all it may concern, that it desires to stand well as a public institution working wholeheartedly, impartially, efficiently for the good of all.

In closing my address I beg permission to quote the final paragraph of the first Reconstruction report, viz.:—

Such then are the proposals, that we commend to the National Council; but we desire, in conclusion, to emphasise the truth that forms are lifeless things without the spirit that animate them, and that no rules or regulations have any value apart from the broad and sympathetic treatment with which they should be handled and interpreted. Administration is at least as much a matter of heart as of brain. Throughout our deliberations we have striven to promote what we conceive to be the best interests equally of the State and of the Civil Service, we have endeavoured to remedy what has appeared to us to be defective while, at the same time, not impairing what experience has shown to be good; and in all that we have proposed we have kept steadily in view the ideal of an efficient and contented Public Service."

LONDON TELEPHONE SERVICE NOTES.

THE Controller attended the King's Levee at St. James's Palace on March 7.

* * * *

It has not been the fortune of many connected with the Telephone Service either under private or National administration to be classified with the Saints of old. Our Controller is probably unique in having had this distinction conferred upon him. It happened in the course of a debate at one of the meetings of the City Corporation when a speaker claimed for him a likeness with St. Simeon Stylites. St. Simeon, as of course everyone ought to know, was a Syrian monk in the fifth century, who spent many years of his life on the top of a pillar over 70 feet high and only four feet square, which he caused to be erected in Antioch. He spent thirty years on top of that pillar in meditation and preaching, and ultimately died thereon. Antioch was the Syrian capital and became notorious for its wealth and luxury and

Digitized by Google

for the turbulence of its inhabitants. St. Simeon's endeavour was doubtless to make converts of the wealthy and luxurious inhabitants of Antioch by the example of an abstemious life and by preaching. We are not told what measure of success he achieved, but we may reasonably assume that he met with much resistance where he touched the pockets of the wealthy, and there is little doubt that he received small reward in this world. The high office of Controller of the London Telephone Service was likened to St. Simeon's pillar, but more close is the resemblance between our City and the ancient capital of Syria as regards wealth and luxury and in turbulence as we have experienced it in matters telephonic. Our modern St. Simeon is engaged in an endeavour to convert certain magnates to the view that the claim for a larger financial contribution from them is just, and he must be abstemious for, as the speaker said, his job is worth three times the stipend attaching to it. The comparison appears to be more complimentary than disparaging, and although our chief has been referred to in many and various terms on sundry occasions we doubt whether he has previously been likened to a saint.

Telephone and Telegraph Society.

Mr. Cook's paper, "Studies in Whitleyism," read before the Telephone and Telegraph Society invoked some keen discussion. Mr. Lee's contribution was greatly appreciated. The subject is one which can be approached from several points of view, and time prevented the saying of much that could be said on the matter.

Monday, April 18, is a date to be remembered. Mr. R. P. Crum, who was one of the party which recently visited the United States, will on that date read before the Telephone and Telegraph Society a paper entitled "Some features of the American Telephone System." The meeting will be held at 5.30 p.m. in the Great Hall, River Plate House, Finsbury Circus. Members of the London Telephonists' Society will be welcomed.

Telephonists' Society.

There is little doubt that the success which attended the last meeting of the London Telephonists' Society will ensure a large audience if a similar programme is arranged next year. Miss Dalley's prize paper in the essay competition was accorded an enthusiastic reception, clearly supporting the decision of the judges in awarding it a prize. The main feature of the meeting was the Elocution Competition in which eleven members of the Society took part. The task consisted of the repetition of certain standard operating expressions heard by the audience, who were the judges, through loud speaking telephone equipment kindly installed for the occasion by the Western Electric Company. The five prize winners were :—

Miss J. E. Graves, Operating School; Miss E. J. Turner, Mayfair Exchange; Miss A. J. Franklin, North Exchange; Miss K. E. Clarke, North Exchange; Miss L. E. Mason, Western Exchange.

Mr. Preston presented the prizes and made a very encouraging speech.

The session has been a very successful one. It closed with a record membership, and members will look forward to next session under the presidency of Mr. M. C. Pink.

Swimming.

The several swimming clubs formed at the exchanges in the London Telephone Area have banded themselves into an Association to be called "The London Telephone Service Swimming Association." The Controller has consented to become the first President of the Association.

New Exchange Work.

The past month has seen the opening of a new exchange known as Langham and also the completion of a new switchboard at Redhill. The opening of Langham was effected very successfully on March 5. Its nucleus was 1,240 subscribers from Mayfair Exchange. It commences with 236 outgoing and 260 incoming junctions and 19 A and 10 B positions working; 13,640 pink pegs were used for the Mayfair multiple in pegging the lines of the transferred subscribers. Two hours after the transfer there were no known internal exchange faults, and as a result of the speaking and signalling tests the engineers had in hand only two cases of faint bells at subscribers' premises and eight line faults. The result was highly satisfactory to both the engineering and traffic staffs.

New magneto equipment has been installed at Redhill, replacing the installation which has done useful work for the past 18 years. The new equipment comprises 5A and 2B positions and has capacity for a total of 540 subscribers. There are 419 existing subscribers and the working junctions number 71. It is accommodated in the same building but not in the old switchroom.

Langham Choral Society.

In the rendering of Mendelssohn's "Elijah" at the Queen's Hall on Feb. 18 the Society achieved a great success. The Press references are highly complimentary and they encourage the Society to go forward with confidence in undertaking still more difficult works. There was an increased demand from the public for tickets, which is an indication of the good reputation the choir is establishing. The hall was full and the financial success of the venture is assured.

By the time these notes are in print the Society will have filled a special engagement at the Royal Albert Hall, and no doubt will have added still further to its laurels.

The last performance by the Society this season will take place at the Queen's Hall on May 10.

Mayfair Exchange.

The spacious ball room of Australia House was the scene of much gaiety and enjoyment on the occasion of the Mayfair Exchange dance. The excellent floor accommodated about 250 dancers, whose steps were accompanied by the syncopations and harmonies of Leonard Coombs' Bon Accord Band. The programme, though quite modern, was sufficiently varied to cater for the tastes and abilities of all. A novel feature was afforded by the coloured lime-light effects, which lent a dazzling appearance to some of the waltzes. The whole evening was as happy as the jovial M.C. Mr. W. Dempsey, to whom the thanks of all concerned are due. The memories of the dance have called for a repetition, and we can confidently say that Australia House will soon be the scene of another such gathering.

Park Exchange.

Kind hearts are the gardens,
Kind thoughts are the roots;
Kind words are the blossoms,
Kind deeds are the fruits.

The above quotation is very symbolic, and indeed true, of a very delightful party given by the staff to 212 poor children at St. Stephen's Schools, Bayswater. The whole of the cost was defrayed from funds collected by the staff, and they are to be congratulated on the excellence of entertainment given, and the amount of cheerful, willing help they individually gave, in waiting upon, and amusing their small guests. To those tiny children from the poorest of homes, and surroundings, the pleasant schoolroom, with its prettily decorated teatables, filled with good things to eat, its toys and gifts, and smiling hostesses, must indeed have seemed a glimpse into fairyland. One felt the pity of it, that such an experience could not come more frequently. After tea, games were played and popular choruses sung with much fervour of tiny enthusiastic voices. These were followed by an excellent entertainment of just the items most loved by kiddies—the daintiest of fairies in the person of Miss Irene Burville danced, then followed two clowns and a conjuror, and finally a real Punch and Judy Show. The few hours sped by all too quickly, and as the small guests reluctantly bade adieu, each was presented with a toy, a bag containing sweets and fruit, and a new penny. To most of the girls, the toy given was a doll, which had been daintily dressed by members of the Staff, and which gave the greatest joy to the delighted recipients. To see the unutterable Mother love shine down from tiny pinched faces upon those dollies, must indeed have been full repayment to the donors for all their kindness in providing the gifts.

Regent Exchange.

Australia House presented a pretty and animated scene, and when Regent held high revel and "tripped the light fantastic toe." Although fancy dress was optional, prizes were awarded, and many quaint and ingenious costumes were to be seen. It was a merry and successful occasion, and the girls are eagerly looking forward to the next.

The staff had a delightful surprise on Saturday, Feb. 5, when their Gifford House *proteges* turned the tables by inviting them to a sumptuous tea and very enjoyable concert, as a mark of their keen appreciation of the efforts made by Regent on their behalf during the past eighteen months. The expenses were defrayed entirely by the men, and the matron and nurses made gracious attendants, who anticipated every want of their guests. In a speech by one of the men it was explained that this entertainment had been devised as a means of conveying to Regent how greatly the men valued the attentions of those who had given them so much happiness.

Tilbury Exchange.

The Queen's Hotel, Grays, Essex, was the venue of a very successful evening of dance and song arranged by the staff. The presence of Mr. C. J. Welch, the Section Superintendent, and of Mr. C. Roberts, of the District Office, was greatly appreciated.

LONDON ENGINEERING DISTRICT NOTES.

ONE hundred and ninety-eight members of the staff from the Headquarters and Sectional Offices were present at the tenth annual clerical supper held at the Bridge House Hotel, London, S.E.1, on Tuesday, March 1. Mr. A. E. Cooke, the Principal Clerk, presided, and was supported by Mr. F. Freeman in the Vice-Chair. The Superintending Engineer, Mr. A. Moir, O.B.E., was "the guest of the evening." Mr. Cooke in the course of his remarks welcomed the presence of Mr. Heath and other visitors. He touched upon the subject of re-organisation, and expressed the hope that the Post Office proposals would soon be published and would be entirely satisfactory to all concerned. He complimented the clerical staff on the manner in which they performed their duties, and stated that the report of the recent Audit had been entirely satisfactory.

In proposing the toast "the Guest of the Evening," Mr. Cooke spoke of the good feeling which existed between the Superintending Engineer and the Senior Supervising Clerical Officers, and made special mention of the successful manner in which Mr. Moir had organised the London Engineering District, which now has a staff of nearly 6,000.

WHERE TO STAY.

BRIGHTON.—Rusthall Boarding Establishment, 11-12, Cannon Place. Central. One minute West Pier. From 2 guineas weekly.

DEAN FOREST.—Severn-Wye Valleys. Beautiful Holiday Home (600 ft. up) 55 rooms, extensive grounds, motors, golf Boarders 47*s.* 6*d.* to 63*s.* Prospectus—Littledean House, Littledean, Glos.

EASTBOURNE.—"The Polytechnic," 109-111, Tideswell Road. Recommended by Polytechnic, Regent Street. Comfortable holiday home. Seven minutes station. Five minutes pier. Liberal table. Piano. Terms, board residence 5*s.* deposit and 2 guineas at end of week.

ILKLEY, YORKS.—Marlborough House Boarding Establishment. Tennis Court. Billiards. Excellent cuisine. Near Moors. Stamp for tariff. Mr. and Mrs. J. T. Robson, Resident Proprietors.

MARGATE (CLIFTONVILLE).—"Lavardin," Edgar Road. Board Residence. Minute Sea. Liberal Table. Highly Recommended. Young Society. Tariff on application.

SWANAGE.—The Highcliffe Private Hotel and Pension. Unrivalled position on sea-front. Near Golf Links. Excellent cuisine. Inclusive terms. Enlarged 1911-1912. 'Phone: 47 Swanage. Mrs. Hooke.

Books for T. & T. Engineers

Just published. New and enlarged edition.

THE TELEGRAPHISTS' GUIDE. By Bell and Wilson. Revised and brought up to date. Cr. 8vo. 250 pp., 156 illustrations. **5s. net,** (Postage 6d.)

"This very faithful 'guide.' . . . The book is lucidity itself . . . . No telegraphist aspiring to a technical knowledge of his profession should be without his copy of B. and W."—*The Telegraph and Telephone Journal.*
"Brought up to date and covers a large number of useful points . . . should be very useful for telegraphists and others."—*The P.O.E.E. Journal.*
"One of the best and most acceptable of all text books on the subject."—*Supervising.*

Also just published.

QUESTIONS AND SOLUTIONS IN TELEGRAPHY AND TELEPHONY (Grade I, 1904-1919). By H. P. Few, Silver Medallist. Fifth edition, carefully revised and enlarged. Cr. 8vo., 328 pp., 225 illustrations. **5s. 6d. net.** (Postage 6d.)

The best book of its class ever written. An invaluable work for students.

S. RENTELL & CO. Ltd., 36, MAIDEN LANE, LONDON, W.C.2.
Specialists in books on Telegraphy and Telephony.

Why don't you Open an Account

SEND a line for the new MODE BOOK. 48 pages of fascinating fashions. You can open an account at Crichtons'. So convenient and economical. A small sum out of your salary each month enables you to purchase your immediate needs. No fuss. No bother.

Coats and Skirts,
Overcoat, Furs,
Raincoat or Mac.
Frocks, Blouses,
Underwear,
Shoes, Trunks,
Sports Coats, &c., &c.

This little-at-a-time plan is strictly private and confidential. Write for the MODE BOOK and full details.

SPECIAL TERMS
to Telephone and P.O. Staff

CRICHTONS' Ladies' Tailors and Outfitters, Ltd
14, Crichton House, Devonshire Sq., E.C.2.
(One minute Liverpool Street).

Photographs in One Minute.

No Plates or Films. **A Second to Take**
No Printing. **and a Minute to**
No Dark Room. **Finish a Picture.**

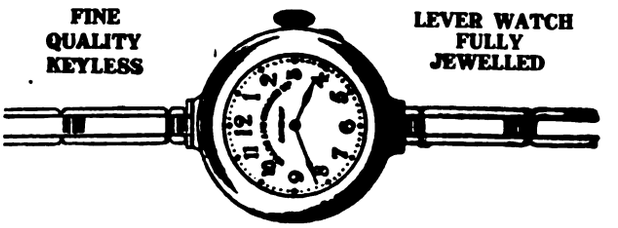
THE MANDEL-ETTE CAMERA takes photographs 2¼in. by 3¼in. direct on to postcards WITHOUT FILMS, PLATES, PRINTING OR DARK ROOM. Camera weighs 24oz. and measures about 4in. by 5in. by 7¼in. Loads in daylight with 15 or 50 cards at one time—NO DARK ROOM NECESSARY. Universal focus lens produces sharp pictures at all distances.
Permanent results.

MANDEL-ETTE CAMERA

Equipped with the new wire release perfect working shutter. Combined 3 in 1 developer eliminates any other solution. Pictures develop automatically in less than a minute—cannot over-develop.

Price of Mandel-ette, including Tripod,		**1 packet of Developer and 15 Postcards** - £3 10 0 carriage free
or without Tripod - - -	£3 0 0	"
Extra for Special R.R. Portrait Lens	£0 15 0	

GRAMOPHONES



of fine tone quality. Also SOUND BOXES, AUTOMATIC STOPS, TONE ARMS (New Design).

A. E. NORTON, 259, HIGH HOLBORN, LONDON, W.C. 1.

Replying, Mr. Moir said that on the occasion of their tenth annual supper, he was glad to be able to assure them that during the decade just completed they had not been standing still. On the contrary, by persistent effort, they had greatly improved the maintenance of the engineering plant. This, he stated, was as much due to clerical as to engineering efficiency. He regretted that delay had taken place in applying the improved reconstruction rates to some of the classes, but he had no doubt that their patience would shortly be rewarded. Mr. Moir announced that Mr. Heath, who had a wonderful topographical knowledge of London, had promised to write an article showing that Denman Street was situated in the area surrounding Shakespeare's South London Theatre. From this the staff would be able to recognise, as they took their walks abroad, when they were treading upon Shakespearean ground. In conclusion, he thanked them most sincerely for the honour they had done him by inviting him there as their guest and for the way in which they had responded to the toast so gracefully proposed by Mr. Cooke.

As on former occasions a very creditable musical programme, all the items of which were contributed by members of the staff, followed the supper. Mr. J. W. Kimber, the musical director, was assisted by Messrs. S. L. Bickerton, E. W. Casserley, T. A. Claydon, C. W. Cornwell, S. C. Edser, A. W. Edwards, C. A. Edwards, J. J. Gerke, H. Gilbert, E. F. Griffiths, Chas. Harris, A. E. Spears, G. H. Stanbridge, H. H. Thorne, A. A. Turner and the L.E.D. Orchestra, led by Mr. H. W. Gardener; Mr. H. Curtis was at the piano. Mr. Freeman proposed a vote of thanks to the artistes and the committee who had organised a most enjoyable and successful evening, and the proceedings terminated with the singing of "Auld Lang Syne."

I.P.O.E.E. Meeting.

On March 7 there was a gathering of the Clans at the Institution of Post Office Electrical Engineers to hear a paper on the Relay Automatic System by Mr. Dipple, of the Engineer-in-Chief's Telephone Section. A paper on Auto-Telephony always attracts a large audience, and on this occasion, not only were there present several colleagues from other branches of the Service, but also several representatives from the firms who make a speciality of manufacturing telephone equipment. It is probably generally known that Col. C. B. Clay, one time Metropolitan Superintendent of the National Telephone Co., is General Manager of the Relay Automatic Co., and it was noted with pleasure that he was in the hall.

To describe an automatic system of telephony in such a way as to ensure the audience gaining a clear understanding of its general principles is by no means an easy task, but Mr. Dipple succeeded very well. He very wisely limited the explanation of circuit diagrams to a few main features.

The Relay Automatic Co., is equipping an exchange with their system at Fleetwood, and in due course the Department will have data which will enable the merits of this system to be gauged when compared with other systems. It certainly has some very promising features, the chief of which is, that practically the whole of its functions are carried out by means of relays, the mechanical appliances used in other systems being non-existent. Although the application of the system to public exchange work is comparatively new, its use for private installations has shown that it can be relied upon to do all that is required of it with very little skilled attention.

Another New Telephone Exchange.

Soon after the Armistice it was seen that there would be considerable delay before any of the new exchange buildings could be completed and equipped with plant. This delay was inevitable and is a direct outcome of the War, and the consequent shortage of materials and labour of the right kind. The only way to meet the need for exchange plant appeared to be to erect a number of exchanges of a temporary nature and to carry out the work by the local engineering staff. The first of these exchanges was opened at Clerkenwell by the transfer and conversion of the Air Ministry P.B.X. from the Hotel Cecil. The second one was provided by using some second-hand sections of the No. 9 exchange type to relieve Battersea, and was called Latchmere. The third was formed by adapting some No. 9 P.B.X. type boards and installing them in a 60-ft. Army hut at Stratford, and so providing the Broadway Exchange. The fourth was opened on March 4. It is equipped for 2,000 lines, and is of the No. 10 C.B. type (40 volt). It is housed on the roof of the Western District Post Office. This building was originally so constructed as to permit of another floor being added if required, so that it was only necessary to provide walls and a roof, the floor being sufficiently strong to carry the weight of a 34 position switchboard with main frame, power plant, &c. Although the exchange is a temporary one the workmanship throughout is of the highest order.

Only those who have actually taken part in an exchange transfer will fully appreciate the careful planning and organisation that is necessary in order to ensure that a new exchange shall be handed over to the Traffic staff as a going concern free from faults. The new exchange which is named "Langham" is a relief exchange to Mayfair, and arrangements were made to divert from Mayfair approximately 1,240 subscribers' lines and to provide the necessary junctions and a proportion of spare wires to allow for growth. In order to do this it was necessary to make many thousands of wire diversions and to connect the new exchange to the existing cable system by a new cable route. Cable bearers were also provided in a light well extending from the basement to the top floor and for this purpose it was necessary to use travelling cradles.

The new wires were "teed" to those which were working on Mayfair Exchange, and precautions were taken to protect these tees during the transfer operations. Subsequent to the transfer the Mayfair portion was cut away and the joints made permanent. The operations were carried through without a hitch. The whole of the external and internal work was carried out by the L.E.D. staff, and all concerned deserved the commendation which they received from the Superintending Engineer. Further relief will be given to the Mayfair Exchange Area when the Grosvenor Exchange, also of the No. 10 C.B. type is opened in a few months' time.

* *

New Toll Exchange.

Good progress is being made in the laying of underground along Ludgate Hill. This work is in connexion with the Toll Exchange which is now being installed in a building in Norwich Street, off Fetter Lane.

Apropos of this, the following was overheard on the top of a 'bus passing St. Paul's Cathedral, recently :—

CHILD : "Why are they digging such a big trench here, Daddy ?"
FATHER : "The Cathedral is giving way and they are underpinning it."

British Industries Fair, White City, Shepherd's Bush.

This Exhibition, which was held during the week ending March 5, involved a considerable amount of work by the Department's local Engineering staff. Provision had to be made at short notice for 300 separate exchange lines. In addition a switchboard for the Board of Trade with 13 extensions radiating to different parts of the building was installed. Four of the direct exchange lines in the Gallery of the Exhibition also were provided with extensions to the main halls. It is interesting to note that the work of wiring the Exhibition was completed and ready for use on Feb. 19 in 20 working days, and in spite of the fact that the cables had to be fastened to the roof girders and in other difficult positions, no mishap of any kind occurred. Nearly one and a half miles of cable was run in the Exhibition on steels and suspenders attached to the roof girders. Other interesting figures as are follows :—

No. of Exhibitors' stalls in the gallery	540
No. of Exhibitors' stalls in the main building ...	560
No. of direct exchange lines	280
No. of call offices...	12

Denman Chess Club.

The attendance of members continues to be very good and interest in the Tournament and "Knock-out" competition has been well sustained. The finalists for the latter are Messrs. Gardiner and Francis.

On the 2nd inst., a match was played between teams selected by Mr. Freeman and Mr. Cornwell. The result was a win for Mr. Cornwell's team by 6 to 4.

A "Lightning" match will be played on the 16th inst. Players must move when the bell rings, every half-minute, or forfeit the game.

PERSONALIA.

LONDON TELEPHONE SERVICE.

Miss L. M. BLAKESLEY has been promoted Supervisor at Hampstead Exchange.
Miss A. F. BERRIDGE has been promoted Assistant Supervisor, Class II, Hampstead Exchange.

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

BY F. ADDEY, B.Sc., M.I.E.E., FELLOW I.R.E.

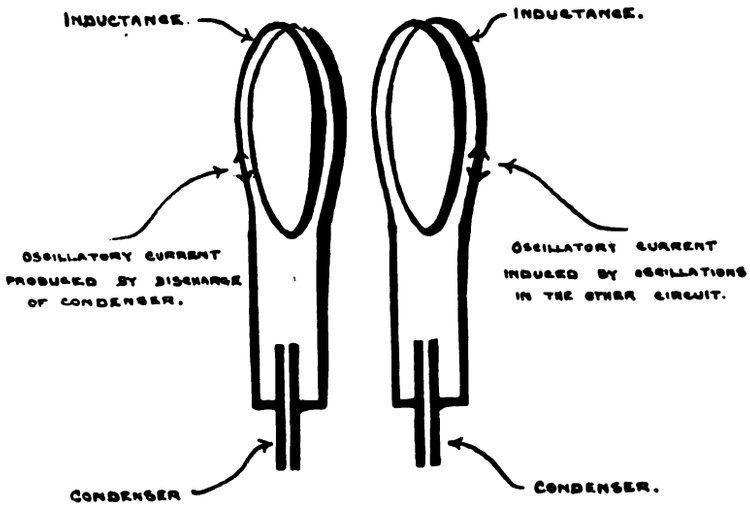
INTRODUCTION.

IN the following series of articles it is proposed to give a popular description of the recent advances which have been made in Wireless Telegraphy and Telephony, suitable for the general reader.

There is no lack of good books and articles on the subject written for the professional wireless man, but for the man in the street who wishes to obtain some intelligent grasp of what is being done in connexion with wireless matters without going too far into technical details, there is very little information available. It is for this type of reader that these articles have been written. Every effort has been made to present the subject in a readable and interesting manner, and it is hoped that anyone who reads through the articles will acquire a sound knowledge of the principles of modern wireless practice.

In order to avoid unduly increasing the length of the articles it has been assumed that the reader has some idea of the fundamental facts upon which the everyday application of electricity are based, such as can be gained from the perusal of any elementary book on the subject. The electrical phenomena of which use is made in wireless telegraphy are, however, less generally familiar, and to enable the reader to be in a position to appreciate what follows, a brief resumé will first be given of these facts. Then, in order to provide a bird's-eye view of the ground to be covered, an outline sketch of the present position of wireless telegraphy and telephony will be given. Afterwards, the various portions of the subject will be dealt with in greater detail.

GENERAL PRINCIPLES OF WIRELESS TELEGRAPH TRANSMISSION AND RECEPTION.



Ether Waves.

Wireless communication between two stations is effected by means of waves set up in the ether, the medium which, as far as we know, pervades all space—certainly all the visible universe. These ether waves are known as "electric" or "electric-magnetic" waves. By suitable means, at the transmitting station, a peculiar strain or distortion is impressed upon the ether, and this state of strain moves away from the transmitting station with nearly the velocity of light, the exact velocity depending on the nature of the ground over which the strain in the ether has to pass, in the same way that a hump impressed on a suspended rope by jerking the free end moves upwards with a velocity depending on the nature of the rope. Immediately after the production of this state of strain, a second distortion is set up, similar in nature to the first, but with the strain in the opposite direction, and this moves away with the same velocity as the first. Following this, at the same interval of time as elapsed between the first and second distortions, a third distortion is produced, in the same direction as the first one, and so on, each successive distortion being in the opposite direction to the preceding one. Since all these states of strain move through the ether with the same velocity, and since the intervals of time between their production are all equal, it follows that the successive distortions, as they move along, will all be separated by equal distances.

A similar state of affairs would be produced in the case of the suspended rope by jerking the free end in opposite directions at equal time intervals. A series of equally spaced humps, alternately on one side and on the other, and moving steadily along the rope, would then be produced.

A pair of such distortions in opposite directions constitutes a "wave." A succession of equally spaced distortions, alternately in opposite directions, is known as a "wave-train." The distance between the centre of any particular distortion and the centre of the next but one, that is, the next one *in the same direction*, is the "wave-length."

When a wave on the surface of a sheet of water meets an obstruction, the strain in the water tends to lift the obstructing body up. If it be free to move the wave will actually lift it. An analogous phenomenon occurs in the case of ether waves. When the strain in the ether happens to pass across a conducting body, such as a vertical wire, it sets up in that conducting body a tendency for a current of electricity to flow, in one direction or the other according to the direction of the strain, and if the conditions are suitable a momentary current will actually be set up. The succession of states of strain in opposite directions, which constitutes the wave-train, will therefore, given suitable conditions, generate a succession of currents in a conducting body across which the waves pass, the currents flowing first in one direction and then in the opposite direction in step with the oppositely directed components of the waves. These pulsating or alternating currents can be detected by suitable devices, and since their existence is a result of the passage of the waves, the devices used to detect them are known as wave detectors, although such devices are actually only very sensitive indicators of the existence of a weak alternating current, and are not affected directly by the waves themselves.

TWO OSCILLATORY CIRCUITS COUPLED TOGETHER.
FIG. 1.

The production of the waves at the transmitting station can be controlled by suitable methods, and long or short trains of waves emitted, corresponding to the morse equivalents of the message which it is desired to send. At the receiving station these long and short trains of waves will cause the detecting device mentioned to be actuated for corresponding long or short periods, and thus communicate the morse signals to the receiving operator.

It is convenient to represent a train of waves in the ether by a wavy line, like the surface of water across which ripples are passing, although we have no idea exactly what the nature of the distortion in the ether may be. The portions of the wavy line representing the train of waves which are above the zero position represent ether strains in one direction, and those portions below the zero position represent ether strains in the opposite direction. (Fig. 4).

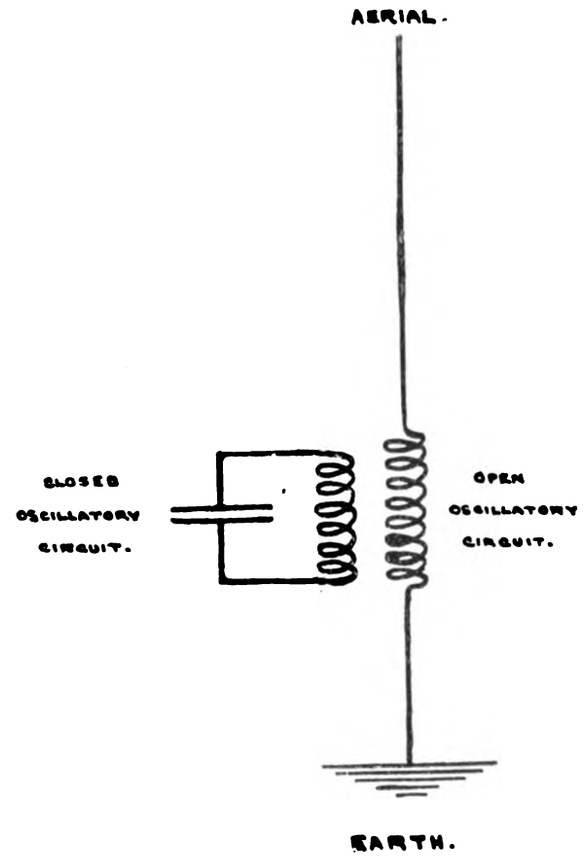
Condenser Discharge.

The simplest way in which a train of ether waves can be set up is by making use of the discharge of a "condenser" through a few coils of wire. A condenser consists essentially of two metal plates separated by some insulating material. At first the electrical state of each plate is the same. The condenser is "charged" by causing a quantity of electricity to be removed from one plate, and accumulated on the other plate. The plates remain in this

Digitized by Google

state till a conducting path is provided between them, when the displaced electricity flows back, the electrical pressures or "potentials" of the plates are equalised and the condenser is discharged. The electrical bigness of a condenser, or its "capacity," is determined by ascertaining how much electricity has to be moved from one plate to the other to set up the unit difference of potential between them.

When the plates of the condenser are first joined by the wire a current flows from the positive plate to the negative plate with gradually increasing strength, and in a very short time the potentials of the plates are equalised. But the current which has been set up in the coiled wire cannot stop immediately the potential difference by which it was started is removed, by virtue of a property of such a wire called "inductance." The current therefore continues flowing and charges up the condenser in the reverse direction, the opposing potential difference set up as the reverse charge in the condenser increases causing the current to die away and ultimately to stop. The condenser then discharges in the reverse direction, and so on. At each successive swing of the charge in the condenser the maximum value of the current in the wire will be less, because the original energy in the condenser is gradually converted into heat by the electrical friction or "resistance" of the wire, and finally the oscillations stop. This is known as the "damping out" of the oscillations.



The action is analogous to the dancing of a weight on the end of a spring. The spring corresponds to the condenser and the mass or "inertia" of the weight to the inductance of the wire. Drawing the weight down from its position of rest corresponds to the charging of the condenser. The weight is drawn up by the spring, but when it reaches its original level this upward pull ceases. The weight is, however, now in motion, and its inertia causes it to continue moving upwards till the downward force set up by the compression of the spring causes it to stop. The weight then moves down, and again overshoots its position of rest. The action is repeated till all the energy which the weight originally possessed by virtue of its displacement has been dissipated.

For a given weight and spring there will be a certain definite period of time in which a complete up and down oscillation will be performed, or, what is the same thing, a certain definite number of complete oscillations will be performed in each second. The time for a complete oscillation is called the "natural period" of the spring-weight combination, and the number of oscillations per second is called its "natural frequency." In the same manner a condenser with its plates joined by an inductance possesses a natural period and a natural frequency for the electrical oscillations set up as already described. The natural frequency in this case depends on the capacity of the condenser and the magnitude of the inductance; the bigger either of these is, the slower are the oscillations, or the less the natural frequency. Similarly, in the case of the dancing weight, the heavier the weight or the "flabbier" the spring, the more slowly the weight dances, or the fewer complete oscillations there are per second. A larger weight corresponds to more inductance, and a flabbier spring to a condenser of greater capacity

Resonance.

If we give the dancing weight mentioned above a series of gentle upward taps, so timed that they occur at just the right instants to help the oscillations set up by the first tap, the distance through which the weight will dance up and down will get bigger and bigger. In the same way, if we apply suitably timed electrical impulses to a circuit consisting of a condenser with its plates joined by an inductance—a so-called "oscillatory circuit"—strong electri al oscillations will be built up. The simplest way in which this can be done is by taking a second oscillatory circuit of the same natural frequency as the first one, placing the wire coils of the two circuits so that they are near and parallel to one another, as shown in Fig. 1, and setting the second circuit into oscillation. When two coils of wire are placed thus, an alternating current in one sets up similarly timed alternating electrical impulses in the other by means of a process called "induction." Since the two coils belong to oscillatory circuits having the same natural frequency, the impulses so produced by the oscillations in the second circuit will quickly set up, or "induce," strong oscillations in the first circuit. The two circuits are said to be "in resonance" with one another, and this phenomenon of resonance between two oscillatory circuits is largely made use of in Wireless Telegraphy.

Two oscillatory circuits arranged in the way described are said to be "coupled" together.

CLOSED OSCILLATORY CIRCUIT COUPLED TO OPEN OSCILLATORY CIRCUIT.
FIG. 2.

The Aerial.

A wire supported from the top of a mast by an insulator, and free from any conducting connexion with the earth, forms one plate of a condenser, the surface of the earth acting as the other plate, and the air as the insulating material between the plates. Such a wire is known as an "aerial" or an "antenna." If the lower end of an aerial be joined to the earth through a coil of wire, an oscillatory circuit is produced. By coupling a second oscillatory circuit, made up of an ordinary condenser and an inductance, to the aerial oscillatory circuit, and arranging that the natural frequency of the two circuits shall be the same, oscillations in the second circuit will set up oscillations in the aerial circuit. The arrangement is shown in Fig. 2. The aerial circuit is called the "open oscillatory circuit," the circuit with which it is coupled is called the "closed oscillatory circuit."

Production of Ether Waves.

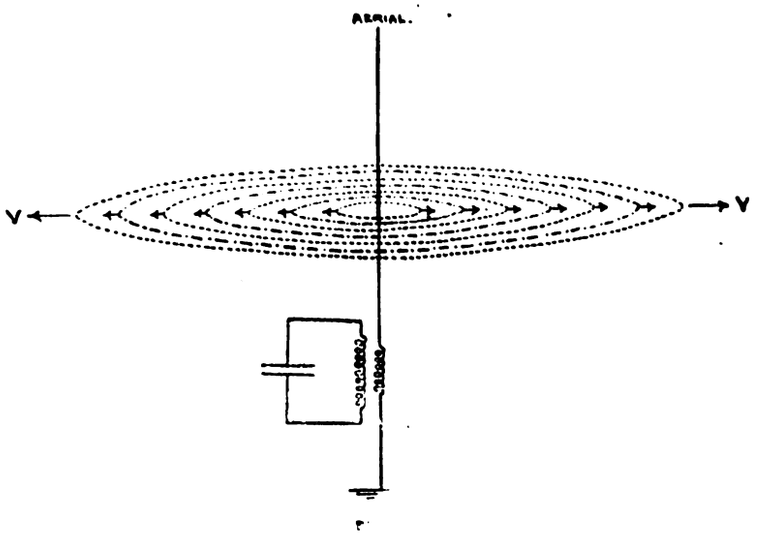
From the shape of the "plate" of the condenser formed by the aerial wire, the electricity which charges the upper portions of the wire has to flow along the lower portions. The further we come down the wire the more electricity has to flow along it, because as we descend there is more and more wire above us to be charged. Consequently, when oscillations are taking place, an alternating current will flow up and down the wire, this current being strongest at the foot of the aerial, and diminishing in strength further up.

Digitized by Google

When the current flows up the wire a ring of ether round the aerial is distorted in one direction, and when the current flows down, a ring of ether round the aerial is distorted in the opposite direction. As already explained, these oppositely directed distortions move away with approximately the velocity of light, the rings expanding like those round a stone thrown into a pond, and constitute a train of electro-magnetic waves. Thus, so long as oscillations occur in the aerial, electro-magnetic waves in the form of horizontal rings will be sent off or "radiated," and it is clear that if the wire be symmetrical with regard to the earth, and the nature of the surface of the earth round the station be uniform, the magnitude of the waves must be uniform at the same distance away all round the aerial. Hence signals will be sent from such a station with equal ease in all directions.

A diagram of what is occurring round such a radiating aerial is shown in Fig. 3. In this diagram the dotted lines represent ether distortions in one direction, and the dot-dash lines ether distortions in the opposite direction.

If we imagine a section to be made of the medium round the wire by a vertical plane passing through the wire, we can represent the waves as they would be cut by this plane by a wavy line, as explained above. This is shown in Fig. 4. Since the current at any point in the wire does not suddenly rise to its full value, and then suddenly reverse its direction, but, on the contrary, rises and falls gradually, the corresponding distortions impressed on the surrounding ether will also increase and diminish gradually. It is because of this that the series of distortions which form the ether waves is truly represented by a wavy line which rises and falls gradually.



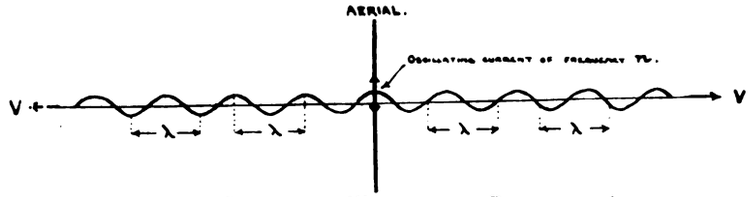


DIAGRAM OF WAVES ROUND A RADIATING AERIAL.
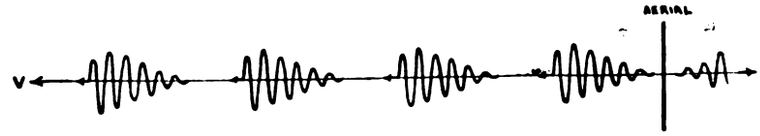
FIG. 3.

Wave Length and Frequency.



It will be convenient at this stage to explain several terms universally used in connexion with wireless telegraphy. It has already been mentioned that in a wave-train the distance between the centre of any distortion and the centre of the next distortion in the same direction is known as the wave-length. Since the shape of each complete distortion is the same, the distance between any part of a distortion and the corresponding part of the next distortion in the same direction is also equal to the wave-length. The wave-length is usually denoted by the Greek letter λ, (lambda). Several wave-lengths have been so indicated in Fig. 4. It has also been mentioned that the waves move away from the aerial with approximately the velocity of light. This velocity is about 186,000 miles, or 300,000,000 metres, per second, and is usually denoted by V.

The currents swing up and down the wire with the natural frequency of the aerial oscillatory circuit. This frequency is usually denoted by n. That is, in one second n complete up-and-down swings occur. Consider now the front edge of the wave sent off at the beginning of some particular second. This will move away with the velocity V, and therefore at the end of that second will have reached a distance V from the wire. But during the second n oscillations will have occurred, and consequently n waves will have been given off. Therefore, in the space V between the front edge of the first wave and the rear edge of the last wave sent off during the second, there will be n complete waves. The length of each wave is λ, and since n of them just fill up the distance V, we have $V = n \times \lambda$. To express the matter in another way; since in the distance V there are n waves, the length of each wave, λ, will be V/n. Of course, λ will be in miles or metres according as V is expressed in miles or metres per second.

DIAGRAMMATIC SECTION OF WAVES FROM RADIATING AERIAL.
FIG. 4.

If we know the value of the capacity and the inductance which make up any oscillatory circuit, the natural frequency of that circuit can be calculated. Thus n is known, and V is also known, for it is equal to the velocity of light. Hence for any given oscillatory circuit it is easy to calculate the length of the waves which it will give off. The waves most generally used for wireless purposes range in length from 300 metres, or about 1,000 feet, to 10,000 metres, or about 6 miles, but both longer and shorter wave-lengths are sometimes employed.

DIAGRAMMATIC SECTION OF DAMPED WAVE TRAINS RADIATED FROM A SEPARATE SPARK STATION.
FIG 5.

Damped Waves.

It has been mentioned that the oscillations, set up in an oscillatory circuit when the condenser is allowed to discharge through the inductance, gradually die away, being damped out by the resistance of the circuit. Consequently the bigness, or "amplitude," of the successive waves radiated from the arrangement shown in Fig. 2 gradually diminishes. Such waves are known as "damped" waves. In the transmission of wireless signals by damped waves the arrangements are such that the condenser is recharged at once after each discharge, and is then allowed to discharge again. A series of wave-trains is thus sent off as long as the transmitting station is in action, the first waves of each train being of large amplitude, and the amplitude of the later waves in a train gradually becoming less and less. The actual first wave is not the biggest, as it takes a few swings of the closed oscillatory circuit before the aerial circuit is set into full oscillation. The waves radiated by a transmitting station using damped waves can therefore be represented diagrammatically as shown in Fig. 5. The spacing between the separate trains of waves is determined by the rapidity with which, after each discharge, the condenser of the closed oscillatory circuit can be re-charged, and the circuits again set into oscillation.

The production of the damped oscillations in the closed oscillatory circuit is associated with the occurrence of electric sparks in that circuit, one spark corresponding to each group of oscillations. Consequently, a transmitting station using a system such as that described above is said to employ "spark transmission." The characteristic of spark transmission is that the energy is radiated in detached trains of damped waves, the separate trains being spaced from each other by intervals depending on how fast the sparks follow one another, or, as it is called, on the "spark frequency."

THE BAUDOT.—XX.

BY J. J. T.

DURING the movement of the entire impression arm Ca, *i.e.*, from its release by the retaining click C (Fig. LV) till it has printed the desired letter on that portion of the paper tape at the moment presented to the type-wheel by the impression cylinder *j*, and has actually been carried by the teeth of V^1 free of the latter and of the type-wheel—until that moment, the paper tape remains in a rigid position on *j*. A small portion is, however, held between the impulse cylinder *l l''* and the compression cylinder *z* and during the forward movement of Ca, the impulse click K engaging with a tooth of the ratchet G of the impression cylinder, a portion of the tape equal to the width of one letter of the type-wheel is passed forward. Naturally, a similar length of tape is drawn up behind it under the pin-guide T. While Ca is being moved back to its position of rest by the oscillating lever L the impulse click K is released from the tooth of G with which it was engaged and engages with the next. In this return movement of Ca the impulse cylinder *l l''* and ratchet wheel G *do not move*, the drum *l'* being as already mentioned, lightly fitted upon *l*, *and* also on account of K^1K^1 the retaining click and spring which prevent any backward movement of G. Briefly, in returning to rest the arm *b* (Fig. LIV) moves backwards on the axle A^{11}, the impulse cylinder *l' l''* is held by K^1K^1 (Fig. LV), consequently a clear portion of paper tape is drawn up with a gentle tension over the head of the impression cylinder *j* (Figs. LIV to LVI) ready for the printing of the succeeding letter.

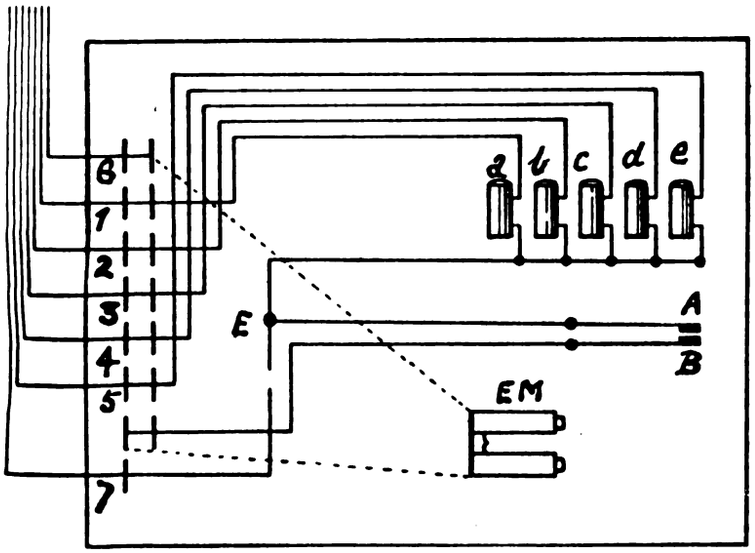

FIG. LVII.

The space between words and groups is made by a similar action, the only difference being that when the impression cylinder *j* rises towards the type-wheel, instead of meeting a letter or figure it meets a grooved blank and the paper is moved forward one letter-space untouched. We have already seen how the change of printing from letters to figures is arranged (Art. XVIII, p. 87).

When studying the Baudot Receiver as a whole, it is interesting to note the complete harmony and economy of movement of the various working parts. Thus the 9/40 of blank space on the peripheries of the printing and type-wheels permit of the return of the impression arm Ca to its position of rest. During this same period, represented by 9/40 of one revolution of the type-wheel, the appendix levers, and the selectors (Fig. XL) are also returned to their normal positions, the former by means of the cam K^1 (Figs. XL to XLIII), and the latter by K^3 (Fig. XL), and the cross-over between the two selection discs, T, T^1. Coincidently with these replacing movements the retaining click C (Figs. LI, LII) the pedal P and the propulsion rod R (Fig. LII) are also brought back to their respective quiescent positions ready for the next movement. It is also during *this same period* that a cam K^1 fixed to the main axle *x* of the receiver (Fig. XLVI) is so positioned on this same axle as to close the circuit of a local battery in its rotation by means of two spring contacts shown diagrammatically (Fig. LVII A, B). The circuit is closed through an electro-magnet EM which causes a cork brake to damp down the speed of the receiver to that of the distributor with which it is connected and thus maintain a rough synchronism. Fig. LVII shows the connexions of the receiver base, the numbered lines representing 1 to 5, the five connexions from Ring I corresponding to electro-magnets 1 to 5 (*a* to *e*), connexion 6 representing that serving the local cadence and brake battery from Ring III of the distributor. Connexion 7 is a common earth. The latter is connected to the base plate of the receiver so that when the latter is placed in position upon it the electro-magnets being themselves connected to the receiver casing find earth together with the brake electro-magnet EM.

(To be continued.)

FROM OCEAN TO OCEAN BY TELEPHONE.

(ABRIDGED FROM THE *Telephone News*, NEW YORK.)

A new record of telephone achievement was made in the course of a demonstration witnessed by the members of the preliminary International Communications Conference at a dinner given them by the American Telephone and Telegraph Company at the Waldorf, New York, on the evening of Oct. 21. They were able to talk and listen over the line of the Bell System from New York to Los Angeles, and by wireless from Los Angeles to Santa Catalina Island and eastward by wire to an Atlantic port and by wireless telephone to the steamship *Gloucester* at sea, and they were also able to hear people talking from the ship on the Atlantic by wireless to shore, by wire across the continent, and by wireless to an island on the Pacific.

This new feat in the art of communication, remarkable in itself, was all the more interesting because it was made in connexion with the dinner given by President H. B. Thayer on behalf of the American Telephone and Telegraph Company and Associated Companies, the Western Electric Company, Incorporated, and the International Western Electric Company, which was attended by some fifty conference delegates representing Great Britain, France, Italy, Japan, and the United States, together with the principal officers of the Bell System and of the General Electric Company and its associated companies.

At the dinner, which was given at the Waldorf-Astoria, they were shown a motion picture descriptive of the building of the transcontinental telephone line. They were welcomed by President H. B. Thayer, and were addressed by Col, John H. Carty, vice-president of the American Telephone and Telegraph Company, who had charge of the demonstration.

Colonel Carty spoke briefly of radio development, and explained the singular advantages of the wire telephone service over land and of wireless telephone transmission in situations where wires could not be used. He referred to the wireless telephone record made by the Bell System in 1915, when wireless transmission was accomplished by engineers of the Bell System, not only across the continent, but from Washington to Honolulu and from Washington to the Eiffel Tower. In this connection he expressed gratitude for the co-operation of the navy in permitting the use of the Arlington Tower and of the French nation in permitting the use of the Eiffel Tower, particularly of the courtesy of General Ferrie, who was in command at the Eiffel Tower, and who was present at the dinner.

Each place at the table was equipped with a receiver, and as Colonel Carty called the roll of the district chiefs along the route of the transcontinental line, the guests heard each answer and learned from each the distance from New York, the local weather conditions, and the local time. As the roll was called a large map hanging on the wall was illuminated so that the course of the connection across the continent could be followed.

Digitized by Google

When the connexion with San Francisco had been established, conversations were held between the British Consul there and a representative of the British delegation, between the Italian Consul and a representative of the Italian delegation in the Italian language, between a Frenchman and the representative of the French delegation in the French language, and there was to have been a conversation in Japanese but for the inability of the Japanese Consul in San Francisco to be present.

Then the connexion was carried down from San Francisco to Los Angeles, and a conversation was had with a representative of the company at Santa Catalina Island. The representatives of the conference found that a communication of over 4,000 miles by wire and of 30 miles by wireless to Santa Catalina was as clear as if it had been from another part of New York City.

The connexion was then established with the steamship *Gloucester*, which had left port four hours before, and unfortunately had not gotten far enough from land interference to make possible the best wireless results. There was also at times considerable static interference. Nevertheless, the conversation between Colonel Carty and his representative on the *Gloucester* was clearly heard, and later, when the conversation was put through from the steamship *Gloucester* to Santa Catalina island, the hundred guests at the dinner were able to hear the talk from off shore in the Atlantic to off shore in the Pacific.

On behalf of the representatives of the delegates for the preliminary International Communications Conference, Mr. F. J. Brown, assistant secretary of the British Post Office, and presiding officer and senior delegate of the Conference, spoke on behalf of his confrères to express their high appreciation of the marvels of the art of communication which they had been shown, and of the hospitality of the American Telephone and Telegraph Company and its Associated companies.

REVIEWS.

"Wireless Telegraphy," with special reference to the "quenched spark system." By Bernard Leggett, A.M.I.E.E. Published by Chapman & Hall, Ltd., ix + 485 *pp. Price* 30*s. net.*

Every student of wireless telegraphy in this country has, no doubt, noticed the lack of information which is available, in English, on the subject of the quenched spark system of transmission.

This system is, however, of great importance, and its use is as wide spread as that of the ordinary spark system.

The present book has been brought out to remedy this defect in the literature of wireless telegraphy. Although the fact that it has been written with a particular aim in view gives the reader the impression that the author is distinctly biased, and is not giving fair credit to other systems, this is perhaps only natural on the part of a writer who is an expert on the particular system which he is describing, and who honestly thinks that it is better than any other. It is not difficult to call to mind other books, both in English and German, nominally dealing with wireless telegraphy as a whole, in which the reader's attention is focussed on the work of some one particular company to the practical exclusion of everything else.

The book under review covers, with the limitation mentioned above, the whole field of wireless telegraphy, and, for engineers and operators who have to deal with the quenched spark system it should prove extremely useful.

"Continuous Wave Wireless Telegraphy." By W. H. Eccles, D.Sc. Published by The Wireless Press, Ltd., 12/13, *Henrietta Street, W.C.2. Part I.* vii + 407 *pp. Price* 25*s. net.*

The use of continuous waves in wireless telegraphy, which has increased so much during the last few years, bids fair before long to supersede entirely the earlier spark methods. The ordinary text book on wireless telegraphy, however, aiming at covering the whole field, cannot give the space to the treatment of this special branch of the subject which its importance deserves, and therefore, the appearance of a book dealing exclusively with continuous waves is particularly welcome.

The student of the more advanced portions of wireless telegraphy usually discovers that he needs to refresh, or to add to, his knowledge of the higher portions of electromagnetic theory. It is, however, not always possible for him to obtain just the information which he requires without devoting considerable labour to searching through various text books, and it is not every professional wireless man who can afford the time for this work. In order to avoid this difficulty, and to make the book self-contained, the author has given, in Part I, the mathematical and electromagnetic groundwork necessary for dealing with the subject. In Part II will be given the practical applications of the fundamental principles set out in Part I.

Part I only has so far been published. The first chapter gives an historical summary of the subject, by which the advantages of continuous waves over the older systems are made manifest. Then follows a chapter on electrostatics and electrodynamics, one on the theory of alternating currents, one on coupled circuits and transformers, and finally one on the physics of ionic tubes.

Throughout the book mathematics are freely used, as it is of course impossible to deal properly with such subjects without their aid. No one, however, who has been through a course of mathematics up to an elementary knowledge of the calculus, should experience any difficulty in reading the whole of the book.

The get-up of the book is good, and the diagrams are very clear. We can recommend it to any one who wishes to go into the subject thoroughly, and we are looking forward to the appearance of Part II, which, if it maintain the standard of the part already published, will make the complete work one which will be invaluable to everyone who has to deal with the higher portions of wireless telegraphy.

TELEGRAPHIC MEMORABILIA.

THE re-organisation of the Foreign Telegraph Department of the C.T.O., London, has resulted in an augmentation of staff and supervision which brings the total number of these two to the very respectable figure of just over 500. The optimists who pinned their faith to the development of the Cable Room and its activities are therefore fully justified. Among these one must place that optimist of optimists, the Controller, who, together with the Lords of the Treasury may well be congratulated upon that foresight which is frequently the truest economy. In the same galleries will now be seen wireless and cable systems working in friendly rivalry side by side and a range of apparatus—Wheatstone, Creed, Morse, Baudot, Siemens and Hughes, &c.—which produces that variety which if not exactly "charming" should certainly drive dull *ennui* far away. There remains, probably some years, of patient plodding and hard work, of co-ordination, co-operation, consolidation before this department reaches a stage of development which shall prove worthy of the best traditions of the winsome craft of telegraphy. No one can foresee what to-morrow's developments will bring forth in the shape of increased speed and increased outputs as regards both cable and wireless international telegraphy. Already the C.T.O. is in daily wireless *touch*—direct or indirect—with Denmark, Germany, Hungary, Italy and Yugo-Slavia, though it be but for a few hours, for each country mentioned has so full a programme that it can only spare, as we also in the present stage of development, at most five or six hours per day as in the case of Berlin, and but two in that of Budapest, Belgrade or Bagnitza. The most pleasing feature, and the most hopeful feature in all these modern advances in systems and apparatus is the keenness and enthusiasm of the younger men.

One visualises these telegraph leaders of the future smiling in the days that are yet to come as they look back on the telegraphic crudities of 1921, while we—brought up on a simple Morse key and a line none too free from "earth," grow petulantly reminiscent of *our* "good old days" when Wheatstone and Creed and Baudot and Murray and Western were good enough for us! This is no fancy of the brain. Modern developments have produced some of the most curious reversals of what we once believed to be immutable electrical law. We know now that Ohm's Law is not true for all conditions. We have learnt that the current in a simple cell travels in exactly the reverse direction to that which we were taught in our early lessons on electricity. We have ceased to believe as once we were told that the current from our battery passes out to line, goes to earth at the distant station and finds its way back through scores and scores of miles to the opposite pole of our battery and to the very identical cell from which it started and thus "completes

Digitized by Google

the circuit!" Is it too much to imagine that there may be other *facts* also which to-day may appear fundamental, but to-morrow—! Does anything appear more solidly established, especially to a submarine cable man than the statement that one cannot signal through a metal conductor unless that conductor is carefully insulated from all moisture? Yet Major-General Squier, Chief Signal Officer of the U.S. Army, tells us that the Research Department of the Signal Corps laboratory, New Jersey, actually signalled electrically (telegraphically and telephonically) between Fort Washington, Maryland and Fort Hunt, Virginia, by means of *bare* No. 12 phosphor-bronze wire *laid in the* Potomac *river*. True it was only a distance of ¾ mile, but the possibilities of this experiment are as great as when Ronald laid those few yards of glass-covered wire in his garden at Highbury and proved the practicability of underground cables. The transmitter of the American invention was "an *electron* tube oscillator which delivered a current of about 270 m.a. to the line at a frequency of about 300,000 cycles per second." Frequencies three times this latter rate were used with success, and as a contrast it may be stated that the limit of the very best present-day submarine cable actually reaches its practical limit at 10 cycles per second. The sober, well-considered result of these experiments is that submarine cables of the future bid fair to be designed on an uninsulated principle, as the use of these "high frequency 'carriers' has the advantage that the chief distortion phenomena of present method transmission are eliminated."

A correspondent sends me an example to add to my list of "false economies" in the case of a Postal overseer, a dear old well-meaning chap, who would insist upon carefully untying every piece of string rather than adopting the shorter and quicker method of cutting the knots, and who could not be persuaded until disciplinary methods were threatened, that the Department's interests were best and most economically served by cutting the string rather than by utilising the valuable time and fingers of an officer of supervising rank for a slow and laborious process.

Records of abbreviations as utilised on Anglo-Continental lines in official conversation when making adjustments have been published in these columns on one or more previous occasions. The following is printed as an interesting example of phonetic French and might well puzzle many a student even well versed in the Parisian lingo. The conversation was made on the occasion of some technical difficulties on the London-Paris-Marseilles circuit. Lyons, the first speaker, being one of the *repeating* and intermediate office, addresses himself to Paris as follows:—

"ALLONS ENFANTS DE PARIS! COMMENT RECEVEZ VOUS? OUI MAIS VOILA 1 MINUTE SEULEMT KJRECOIS ALORS. ECE BON CKJVOUS DI?"

Paris replies:—

"MÉ ENEFET JMLDEMANDE JE RECEVÉ ABSOLUMt RIEN AI JUSTE PASSÉ PAPIER SUR KTAKT DU RLAI KI MONT PARU PROPR CPDt CADVE VENIR DLA SUREMt."

Lyons acknowledges above from Paris and calls Marseilles:—

"OUI VESRMSEIL. OHÉ OHÉ M. LA CANNEBIÉRE."

Marseilles who has been watching replies to the call of Lyons thus:—

"OHÉ LA BUTTE" (La butte—the little mound, a sarcastic acknowledgment of the hills upon which the city of Lyons is built).

"ICI LA CANNEBIÉRE" (Cannebiere—a well known boulevard of Marseilles) "ESCE LA BUTTE KIEST LA?"

Lyons replies in similar strain:—

"AH TE SALUE PANTRUCHE TT EST BON MSI VCI LONDRES,"

and switches the Marseilles section through to London.

Marseilles immediately turns his attention to the British end of the thousand miles line with a cheery call and salutation of:—

"OHÉ LA TAMISE! OHÉ LA TAMISE! ICI LE BO SOLEIL DE PROVENCE KI TENVOIE KKES RAYONS DORÉS. PUIJE FAIRE GLISSER X?"

We give the word to commence traffic in briefer, less flowery, but not less good-humoured terms, and work commences.

Is it waste of line-time? In a way and from a strictly scientific point of view, "yes," but these few moments—and the words are signalled and printed in much less time than it takes one to write them—have established not only good electrical communication but a good working atmosphere, which has a value not expressible in terms of costs and works accountancy. Anyhow, it is Anglo-Continental telegraphy, one phase of it.

The April number of the *P.O.E.E. Journal* is a particularly interesting one. Mr. Myles Hook, M.B.E., &c., continues the interesting account of Submarine Cables of the World, together with a brief account of the work of the British P.O. cable ships *Alert* (I and II), *Monarch* (I and II), the war-time cable ships, *Hodder*, *Mersey*, *Sialkot*, and *Madis*. All of the afore-mentioned boats were under the charge of P.O. engineers, and did some risky and amazing cable work. The *Sialkot*, though a converted trawler, carried out deep water work in the Bay of Biscay, diverting and repairing cables which "many had deemed beyond her powers." The *Madis*, originally built at Lowestoft as a North Sea drifter, was only 91 feet long, may surely be accounted the smallest cable ship in the world, and proved invaluable for shore and island work in the neighbourhood in the Firths of Forth and Tay

Our old friend, A. C. Booth, gives an account of Recent Improvements in Baudot Apparatus, and a modest description of the Booth-Baudot keyboard Tester, the practical value of which one cannot wish to deny. It only remains for one each of these "testers" to be loaned or presented to each of the foreign administrations with which this country is in direct communication to complete the conviction of their special utility.

Could one have looked in at the Strand Palace Hotel about tea-time on the 6th of last month, a goodly representative gathering of pensioned T.S.-ites, hale, hearty, merry and bright, might have been seen regaling themselves with the cup that cheered but did not inebriate. Judging from the united ages of the following twenty names telegraphy must have something of the elixir of life in its make-up to produce so healthy a collection of the genus homo. The names of those present at this happy little re-union were:—H. E. Adams, J. Bailey, I.S.O., F. Barfield, A. Bathurst, E. Bird, R. W. Cutler, C. Elphick, F. W. Fryatt, A. Gordon, E. L. Hilton, J. G. Hopgood, W. J. H. Joyes, C. S. Keen, R. E. Kemp, A. C. McEwan, A. Morgan, H. Trollope, A. W. Ward, W. J. Warmington, W. A. Webster.

It is realised that there are times when the "Morning Test" of telegraph lines is a real irritation to the Commercial Branch, interrupting as it does the flow of traffic at, with some towns particularly, most inconvenient moments. Nevertheless, the necessity for a regular record of the electrical value of each conductor maintained by the Engineering Branch should be easy of recognition by the technically qualified officers of the commercial side. The need as a necessity is on a par with the regular testing of railway bridges and lines. The fact that a line is actually working is no proof that it is faultless, and the aim of the engineers is that very laudable one, the discovery of *incipient* faults. This little screed on the subject is due to the receipt of a humorous complaint in verse, which neatly tells off the actual situation from the commercial point of view, and although it is impossible owing to the demands upon space to publish all the verses, one has witnessed inopportune morning tests which might well have produced the following from the very heart of a telegraph superintendent with heavy traffic on hand:—

"What brooks it that our fishing wires
Just sending out the price of 'fryers'
Are cut in mid career?
Though language used be of the gate
Which Billings speaks when full irate—
Not English—but much freer!"

The calls for economy in Government offices which periodically appear in our history under the alluring alliteration of "Retrenchment and Reform" are almost sure to bring in their train "economies" which are only such in name. *Ink powder*, which at the end of a day or two results in thick unusable mud, which has to be thrown away, pencils that break before they are half used, and lower grade writing paper which splutters the pen, and results in an offence against neatness, are fair types of well-intentioned "economies," which are doomed to failure so far as regards real output and real interest in the work in hand. There is also the attempt to apply mere figures and averages to every set of circumstances without discretion. This, one has seen in the stafling of important wires in times of stress. Circumstances could be easily conceived in which "averages" applied to a telegraph circuit which had for its object the watch and ward of a portion of our sea-coast would not only prove *un*economical but actually criminal.

J. J. T.

THE PASSING OF A TELEGRAPH VETERAN.

ON March 9 last, after a painful illness, one of the pioneers of the Telegraph Service, Mr. John Russell, was laid to rest in the cemetery at Elmer's End, Beckenham, at the advanced age of 80 years. "Jack," as he was more affectionately known to his confréres, commenced his telegraphic career in the Electric & International Telegraph Company in June, 1856, and remained with that Company until it, with others, was absorbed by the Government. In 1871 he was made Clerk in Charge for night duty. From September of that year until August, 1879, he held the rank of Principal Superintendent for night duty; that of Superintendent to October, 1894, and Assistant Controller from that date until he retired on Nov. 1, 1902. With the exception of the last few years of his service it may be said that he performed night duty continuously. That such work was not detrimental to his health has been amply demonstrated by his four score years of vigorous health. He was the exemplification of health and vigour throughout his service, and it seems but yesterday that with his cheerful and breezy activity he was interesting himself to see how early he could release the "Short nights," the "11 p.m.'s," and the "Specials." Although somewhat autocratic in his methods he earned the esteem and appreciation of his staff by such interest, and as a result he knew that he could always rely upon his men when business was beyond the "brisk" stage for any assistance.

Assembled at the graveside to take a last farewell were many old colleagues including Messrs Fisher, Fisk, Hopgood, Elphick, A. Bathurst, Moul, Druitt, Keen, Worthy, Poole and Bent. Among the numerous floral emblems was one from the Controlling Officers and Staff of the Central Telegraph Office.

Miss F. A. Russell, Chief Supervisor, and Mr. J. Russell remain in the Central Telegraph Office to carry on the telegraphic traditions of their father.

The Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. MAY, 1921. No. 74

QUALITY OF SERVICE.

A SOMEWHAT unobtrusive paragraph in our London Telephone Service correspondent's notes contains a few operating statistics, which we think might astonish a thoughtful telephone user, although they present nothing novel or arresting to the telephone official. We think also that they might astonish a philosopher, if indeed it is in the truly philosophical temperament ever to be astonished, and furnish him with yet another text on the difference between the real and the imaginary, between the phenomena of hard fact and those which exist only in the realm of conjecture. Many would have us believe—although of course the opinion of the inarticulate majority is always unheard—that the London Telephone Service is incredibly bad. Only a sojourn in other lands and a comparison with other systems will effect a cure, for the axiom of many home-staying subscribers seems to be that the telephone service is always better in almost every other country that in their own.

The figures to which we refer show that the percentage of times a London subscriber is "cut-off" are .56 as against .60 before the War; he obtains 4 per cent. of wrong numbers as against 3.5; whilst the speed of answer was 5.9 seconds in December last as against 4.8 seconds in June 1914. It is actually now 4.7, a decimal point better than before the War. Subscribers imagine they wait minutes for a reply from the exchange, while figures show that, on the average, they are waiting seconds. Some subscribers indeed, know, from painful experience, that they have at times waited an unconscionable period; but how rare that experience must be is demonstrated by the fact that if it were reasonably frequent, the average would be sensibly affected, for it requires no complicated mathematical calculations to show what the effect of a few cases of three, four or five minutes' delay would be on a general average of five seconds. The tests on which these figures are based are not made for the general information of the public; they are made for the guidance of the traffic officer who is constantly striving to effect an improvement in the results. The tests are practically continuous during the day time and the data are gleaned from the lines of subscribers of all classes. The public, of course, are not moved to emotion by learning that the "speed of answer" is reduced from 4.8 to 4.7 seconds, and might possibly consider that to strive to improve on that figure would be like gilding refined gold. They would probably be incredulous if told that the telephonist answered within 10 seconds. Again, few subscribers realise that the average time in which the answer of the called subscriber is obtained is 37.7 seconds, yet this is the average for the whole complex junction-line system of the London Telephone Service. We submit that a little over half-a-minute is not a discreditable period in which to carry out such an operation, and we are certain that the public would be both astonished and content if they realised that the average service is what these comprehensive and carefully obtained tests show it to be.

Why is it then that such a contrary opinion seems to prevail? Setting aside the question of the silent majority whose opinion of the service might be more favourable, we think that two main causes operate to form the opinion of the more vocal minority. One is the incurable inaccuracy of the average man in handling figures and data which do not refer to his own business, the confusion of impressions with facts, and the treatment of the statements of others as though they were his own experiences. The other and more powerful cause is the habit, from which few of us are exempt, of allowing one abnormal experience to outweigh scores of normal ones. One or two irritating delays in obtaining connexion (one perhaps, by an unfortunate chance, a very important one) annuls the good effect of days of prompt service and creates an altogether false impression of the average time of connexion. If we claim that the London Telephone Service is good, we hope we shall not be charged with complacency. As we have mentioned, the statistics at which we have glanced are obtained for the guidance of those whose constant care is to improve the service. To them the increase of a figure from 4.7 to 4.8 is a matter of concern, whilst the subscriber imagines that he would be happy if it were 5. With this zeal in action a further improvement may be looked for, but it is interesting to note that the standard of 1914 has already been regained.

HIC ET UBIQUE.

THE latest revision of rates of which we have information is that which came into force on April 1 in Italy. In the larger areas (those with upwards of 10,000 subscribers) the rate for large business and industrial concerns, banks, hotels, cafés and bars is 1,000 lire £39 13*s.*); for smaller business houses, 700 lire (£27 15*s.*); for other categories, £19 17*s.* and £13 8*s.*; whilst journalists are favoured with a £10 6*s.* rate. It will be seen that although a flat rate is retained a pretty stiff charge is made to the large user.

ACCORDING to the *Morning Post*, the telephone tariffs of the Anglo-Portuguese Telephone Company which operates in Lisbon and Oporto, have now been raised 130 per cent. above those fixed in June 1920.

MR. E. H. BENNETT has been appointed Manager of the Guernsey States Telephone Department in the place of the late Mr. R. McLean. For the last seven years he has been Engineer to the Oriental Telephone Company at Singapore, after experience in the Portsmouth and Brighton Corporation Telephone Departments and subsequently in the Post Office. The Singapore exchange has singularly enough almost exactly the same number of lines as Guernsey, viz., about 2,600.

THE Select Committee on Telephones, 1921, began their sittings on April 6, when Sir Evelyn Murray was examined. The Secretary continued his evidence on the 11th, and Sir Henry Bunbury, Comptroller and Accountant-General (accompanied by Mr. Pearson) was examined on that date and on the 13th. On the 18th Mr. Robbins gave evidence on behalf of the Press Association.

THE late W. S. Gilbert told us in his witty way how he would have made the punishment fit the crime, and from a comprehensive abstract of International Telegraph Laws, recently issued at Berne, we learn how Argentinians legislate for telegraph crimes. If the culprit violates the secrecy of a telegram, he is liable to a fine of 1,000 piastres or 12 months' imprisonment. If he stops communication by intentionally interrupting the lines or cutting the wires, he may be called upon to pay 500 piastres or to serve his country without pay for six months. But an attack on or violent resistance to a telegraph officer being apparently an almost justifiable act can be performed at the moderate charge of 200 piastres or 2 months' honorary employment.

Some of the hostile critics of the Telephone Service in this country would apparently like to go one better on our South American friends and offer prizes for assaults on telephone staffs.

SOME months ago we ventured on a modest prophecy that the number of telephones in the United Kingdom would reach one million by the end of the financial year (31st March). Complete returns were not to hand at the time of going to press and estimates have been resorted to in the case of two districts not of the largest size. The result is a total of 998,000 telephones, of which 982,000 are Post Office stations, 13,300 Hull Corporation, and 2,600 Guernsey. But for the removal of the large system installed for the Ministry of Munitions (2,800 stations) which adversely affected last month's returns, the million would have been passed.

RECONSTRUCTION OF TELEGRAPH AND TELEPHONE SYSTEMS IN BELGIUM.

In spite of the utter chaos existing at Armistice and the setback in reconstruction due to severe snowstorms of last January, the Belgian Telephone and Telegraph Department states that up to July 1, 1920, 282 central telephone offices out of 283 had been re-established. Of telephone subscribers in 1914, 80 per cent. have been refound. It is curious to note that at Antwerp, Malines, and Turnhout there are now more subscribers than before the war. In Brussels there are 14,700 out of a pre-war 18,400, and at Liege about 4,000 out of a previous 5,000.

Reconstruction, it is said, would have been more rapid but for the complete removal or destruction of all copper wire and other material by the Germans. On the eastern lines not a single wire was left. In Brussels, the large and spacious installations were hacked. Some of the commutators have been found in Berlin, and engineers sent to recover them. The material taken from Brussels alone is valued at more than 2,000,000 francs, and that from Belgium as a whole at more than 70,000,000 francs (pre-war basis). *Telegraph and Telephone Age.*

IMPERIAL TELEGRAPHIC COMMUNICATIONS.*

BY A. AVERY (*Central Telegraph Office*).

THE title of this paper is understood to refer, principally, to the cable connexions between the British Isles and our distant colonies beyond the Atlantic and Pacific Oceans, but it will probably be of interest to many of you if a sketch be given of the events which led up to the accomplishment of these valuable and highly desirable means of communication between the homeland and our oversea kith and kin.

Although there had been many agitations for a system of cables, connecting the Colonies with the Mother Country, prior to the year 1915, the British Post Office had no experience of long-distance cable telegraphy and the mysteries of syphon recorder working were a closed book to it. This vital branch of telegraphy had been always in the hands of private companies.

The war in this—as in many other ways—brought unlooked-for necessities, and in the above-mentioned year, urgent need arose for direct means of communication with our then Allies, the Russians. Existing routes were obviously untrustworthy. A cable was laid between Peterhead on the Aberdeenshire coast and Alexandrovsk—a small town built on the shore of an inlet of the White Sea on the Kola Peninsula. This operation was carried out with the greatest secrecy, the cable ship *Colonia* in an endeavour to throw dust into the eyes of the enemy, having, as a preliminary to starting the real work gone cruising for three weeks previously in quite another direction. In passing, it might be mentioned that, in spite of all this manœuvring and secrecy, on the morning following the completion of the cable laying, the fact was mentioned in the columns of the *Cologne Gazette*.

This cable, with a long land line containing two repeaters, gave us direct communication between the Central Telegraph Offices at London and Petrograd, and many telegrams from countries south of Russia, such as Greece, &c., passed over this cable in making their circuitous journey from the Levant to various parts of the world.

Our own Central Telegraph Offices supplied a staff to take charge of the Russian land line and the Eastern Telegraph Company provided a complement for each end of the cable, together with the necessary cable apparatus, and Post Office clerks took charge between Peterhead and London.

Out of the association of our own with the Eastern Company's men at Peterhead grew the ability of Post Office clerks to operate long-distance cables, for within a year or two they were able to take over the cable working between Peterhead and Alexandrovsk. These men were the forerunners of the Post Office cable staff.

I would like to pay a tribute here to the good work of the Russians who had been gathered by their Government from the larger towns of that great Empire. They would sit and "punch," *i.e.*, hand-perforate cable and Wheatstone slip, uncomplainingly the whole day long and show no signs of fatigue. They also, in good time, mastered the difficult task of cable operating. Their efforts to communicate their desires over the cable in our language, after the Englishmen had left them to manage alone, were sometimes very quaint. On one occasion I call to mind, they wished us to increase our transmitter speed and sent us a service message, saying: "Sir, please augment your quickness." On another day an incident happened which seemed to call for a mild complaint to their officer in charge. In response to the service message addressed to the Superintendent, Alexandrovsk, the reply came: "Mister, we have no superintendents. We do the work!" Some of us thought at the time that this possibly contained a subtle insinuation. They proved their mettle shortly after, when five enemy submarines made an attack on the little settlement. The instrument room was set on fire, but the staff managed to salve enough apparatus to enable their capable engineer to rig up a simplex installation, and they were working to us again within three days. When asked later what had happened to the submarines, all we could elicit from them was: "They were all cancelled."

For a considerable time past the working of this, our first long-distance Imperial Cable, has been under a cloud on account of political difficulties, but with the recent signing of the Trade Agreement between Great Britain and the Soviet Government, we believe that it will, in the near future, prove a boon to both countries, and a busy channel of goodwill and good business.

During this period a more important Imperial link was being thought of. In July, 1916, a number of supervisors and staff from London, Manchester, Liverpool and Birmingham, were handed secret and confidential instructions to proceed to Peterhead, and many were the guesses at the respective headquarters as to the "why and wherefore" of their mission. To the principals themselves it appeared to be a somewhat formidable job to be up against, for they were all veterans of the "Morse" persuasion. All the young men were already booked for Military service. At first it seemed that the fence would be too high to clear, but "dogged does it" and in a year or so they

*Paper read before the London Telephone and Telegraph Society on March 21, 1921.

Digitized by Google

emerged from the struggle as passable cable operators. About this time a message came through from London, "a supervisor and three syphon operators to report here on Monday next." Many had been the conjectures as to where these embryo cable men were to blossom forth, and no one had imagined the Metropolis. The quidnuncs had said: "Some pleasant seaside resort in the South of England," but no one "London!" They did not know then that clever engineers had made it possible to "repeat" from a cable over a long land line.

Evidently someone had blundered. This noble four arrived south and were informed they had to open an Imperial cable across the Atlantic, with the aid of nine learners at the Central Telegraph Office! It were better not to recall the comments of the chief actors in this little drama. Still the opening had to be done, and it should be put on record that these devoted civil servants "stuck it" three days and nights continuously while the secretariat were scouring the country for re-inforcements.

The fight, these tyros found, had only started. They had had no experience of commercial cable practice, and many were the pitfalls which presented themselves day after day. Nevertheless they won through, and each month has improved on the past one, until at present, the British Post Office can fairly compare with cable workers of life-long experience.

The early days of the Imperial Cable were one long fight with pressure. These were the times when our brave colonials of Australasia and Canada were in the thick of the fighting, and their long lists of casualities, which had to be signalled, made heavy demands on the endurance of the new cable staff. It was no uncommon thing for the Colonial Headquarters staff, to hand in a despatch containing 10, 12, 15, and even 17 thousand words, which had to be sandwiched in sections between the general traffic, and sometimes covered whole periods of 24 hours, for cables never sleep: their wakefulness is too valuable to their owners.

A word or two as to the place of the Imperial Cable in the All Red Route should now be said. It had long been the desire of the English and Colonial Governments that a complete route, touching only British territory, should exist, and a commencement was made a few years previously by a line from Australasia to the western seaboard of Canada. A composite body, called the Pacific Cable Board, with headquarters in London, was formed of English and Colonial Government representatives, in the proportion of Australia 2, New Zealand 1, Canada 2, and the Imperial Government 3, including the Chairman.

The war with Germany provided the opportunity for supplying the final link across the Atlantic. One of the German Emden-New York cables was cut in the English Channel and brought into Penzance, the distant section being picked up on the other side of the Atlantic, and about 300 knots joined thereto, to take it into Halifax, Nova Scotia. Owing to many of the Pacific Cable Board operators having joined up, a number of our own Peterhead-trained syphon operators had to be requisitioned to operate from the Canadian side.

The ramifications of the All Red Route are extensive, and constant working of the Imperial Cable seems to bring one very close to the far-flung corners of our Empire. When the Superintendent at the Central Telegraph Office is daily communicating with the Superintendents at Auckland, Sydney, Suva in the Fijis, Montreal, and Halifax, the world appears to have become much smaller. The route serves the whole of the South Pacific (and names of Stevenson's haunts are familiar words in the Imperial Section), Canada, the United States, and the West Indies.

Westward traffic arriving at Halifax is disposed of as follows:—the whole of the Pacific work is "gummed up" in the syphon character, and the operators "punch" from this, for transmission across the Continent to the Pacific Coast. The terminal traffic for America is handed to the Canadian Pacific Railway Administration for disposal over the Canadian and United States landlines, and that for Bermuda, the West Indies, British Guiana, &c., to the Halifax and Bermuda Cable Company. All these connecting companies are located in the Dennis Building, which also houses the Imperial Cable staff and plant.

The path taken by the All Red Route is, London to Halifax, through automatic repeaters at Penzance, and the Island of Fayal in Mid-Atlantic; Halifax to Bamfield (a small place in Vancouver Island on the western seaboard of Canada), by Wheatstone duplex, through eight automatic repeaters; thence to Fanning Island (a small island of coral formation in the middle of the Pacific Ocean). This was one of the first of the cable points attacked by the German Fleet. One day near the commencement of the war a German cruiser accompanied by a collier hove in sight. A couple of boat's crews landed and made at once for the cable station, smashing everything.

They then overhauled the papers in the office, and discovered therefrom, the place of concealment of duplicate apparatus. This they dug up and destroyed, and then cleared off. The next morning the officer in charge of the station performed a fine piece of emergency work. Utilising a homely pickaxe, he constructed a grapnel and managed to pick up the ends of the broken cable which the Germans had severed. He then improvised a wooden raft, which he anchored, and then fastened to it the broken cable ends, and made a through connexion with a piece of covered copper. He then constructed a primitive set and got into communication with Suva and made known his plight.

This (Bamfield to Fanning) is the longest single stretch of ocean cable in the world. From Fanning the next step is to Suva in the Fijis, from whence the route is *via* Norfolk Island repeating station to Auckland, New Zealand, and on from there to Sydney, with an alternative route, Norfolk Island to Southport, near Brisbane.

When one endeavours to visualise this varied and lengthy path it seems a decent performance to get test-match score telegrams, off the Adelaide, Sydney, and Melbourne cricket grounds, as we have been doing recently, in 15 to 20 minutes, especially when it is remembered that there are 7 or 8 transmitting points to be negotiated.

Our Controller brought off a little stunt last summer. He offered His Majesty the King the opportunity to send Prince Edward the result of the Derby, and without any elaborate preliminary arrangements got it into the hands of the Prince at Sydney in less than twenty minutes.

The Imperial Cable section of the All Red Route possesses some of the most recent developments of cable telegraphy, the inventions of the capable engineers of the Eastern Telegraph Company. The transmission both at London and at Halifax, is done by Judd and Fraser converter cable transmitters. These are automatic, and by the use of a switch, will take either the Morse or cable type of perforations. A speed of about 30 words per minute is maintained at duplex. This is very constant, and only on rare occasions has simplex working been necessary, due to interruption of the circuit from a variety of causes. The tape for feeding these auto-transmitters is prepared both by hand and keyboard perforators at both ends alike, but the method of reception differs. At Halifax a vibrator syphon recorder is in use and the slip with its syphon characters is "gummed up" and from it punchers prepare tape for Wheatstone transmitters, signalling across the Continent to Vancouver.

In the homeward direction, novel and interesting apparatus is in use. The signals arrive at Fayal from Halifax in block form, that is, owing to the great electro-static capacity of the cable the separate pulsations of dots and dashes have become continuous curves of their respective signs. They here actuate a relaying instrument called an interpolator, which, being synchronised with the Halifax transmitter, breaks up these block signals, and sends them on to Penzance as perfect and separate pulsations, just as they started from Halifax. By the time they arrive at Penzance, they have assumed block form again, and a special repeater passes them on so to London. Here they have a double function. Not only do they actuate the usual syphon recorder, which is placed in the bridge of the bridge-duplex, but also operate a couple of Post Office standard relays, placed in the line circuit of the land line loop. One of these relays responds to the dot, and the other to the dash current. In turn these relays, through their local circuits, operate selector sounders, which, again, in turn energise the respective dot and dash magnets of a cable reperforator, which transforms the syphon characters into Morse perforated tape. This being passed through a Creed printer, gives a record in ordinary Roman type. It should be mentioned that an exceedingly close synchronism is necessary here, as at Fayal, for successful results to be obtained. The cable reperforator is very complex in construction, and quite a bag of tricks of clever devices, and it will be appreciated that with only about 2 per cent. of margin for variation, a good deal of nursing is necessary in order to maintain constant working. In practice, the syphon slip is "gummed up" and serves to provide an office copy, while the printed one, gives an excellent copy for the public.

There are some faults and interruptions met with in cable telegraphy which appear novel to those who have been familiar only with land line working. For example—now and again a laconic message is received: "Lightning, I now earth cable." It will be pretty obvious to all that the high value of a cable renders it very necessary that no risks to it should be run from such a danger. On a recent occasion Penzance was obliged to keep the cable earthed for three hours. Earth currents are a source of not infrequent interruption, especially in the vicinity of the Azores. The outward repeating relay at that station is of the drum form. The cable coil is joined to a tiny conductor, which in its zero or neutral position, rests on a very narrow metal segment insulated by thin mica segments of a small drum, kept rotating, to obviate friction, by a little motor. The deflection of this conductor off the mica segment gives the necessary local circuit for relaying the respective dot and dash currents. It can easily be imagined what a job it is to keep this delicate arrangement in alignment when earth currents are about.

What has struck us as the most curious cause of interference has been that due to humidity at the Azores. It should be explained that on a duplexed cable the artificial line, or, as we call it, the compensation circuit, is a formidable thing, weighing two or three tons. It is made up of resistances and condensers with which to balance as closely as possible the electrical conditions of the cable. It is generally built up in a separate room. In these humid times, with a hot and "perspiry" atmosphere, all the connexions are reeking with moisture, and the poor electrician has to light large lamps in an endeavour to dry out the damp. Meanwhile he is unable to maintain duplex working, and resort has to be had to "up and down" turns at simplex.

Some interruptions, which cannot be placed in the category of ordinary faults, have happened to the route at various points. The first serious one was due to some uncertain cause in deep sea between 260 and 300 miles from Penzance and not only this, but two other cables were broken. Owing to submarine activities it was not possible to repair these until fourteen months had elapsed. A very recent interference was due to some Halifax local

Digitized by Google

authority who, having to blast frozen ground near our conduit, managed to break it, and narrowly missed making a complete stoppage of both the imperial and Halifax and Bermuda Systems. On another occasion a big landslide on the Canadian Pacific Railway carried away some miles of rail and telegraph lines. These lines are also subject to breakdown due to heavy falls of snow, but it is remarkable how very quickly restoration is made in these cases.

Still another cause of trouble on the 3,000-mile Trans-Continental land line is the intermittent presence of electric storms. Cases have occurred in our short experience in which the apparatus at some of the repeater stations, has been absolutely burnt out by the inrush of these heavy currents.

Sometimes we have felt that the Imperial has a charmed life. On one occasion seven other cables in its vicinity were interrupted.

The most amusing interruption was when the Controller had invited the Lord Mayor and the Sheriffs and Aldermen to come and see the Imperial Cable and the Central Telegraph Office generally. Everything was in readiness. The cinema man was installed, the Lord Mayor momentarily expected, the red carpet had been laid and the anxious Controller was at the front door. The Lord Mayor's carriage drew up, and at that minute the cable was interrupted. Happily it came right during the time the Lord Mayor was signing the visitors' book, and when he reached the circuit with Mr. Illingworth all was going merrily and the cinema man got his picture.

It has already been mentioned that the working speed of the Imperial Cable is 30 words per minute at duplex, but our engineers hope in the near future to be in a position to instal amplifiers by means of which the rate of signalling will be increased at least 30 per cent. These wonderful devices, of which a number of forms are in use, enable the conversion of the miscroscopic signals due to the increased speed into characters of readable size.

At a time like the present when there appears to be an almost universa desire to throw mud at Post Office institutions, a word or two anent our relations with the business world may be of interest. When it first became known by us that the projected Imperial Cable would have to enter into competition with the Cable Companies, it was viewed as a stiff proposition: for it was feared, that the department which—to its credit by the way—would have to mete out equal treatment to great and small users, would start greatly handicapped. This has proved to be the case, but the Secretariat has steered the ship through uncharted waters so well, that no point has been available for attack.

It will be understood how difficult it has been to apply rules solely to Imperial Cable affairs, which cannot be applied to foreign traffic generally, but, as difficulties have arisen in this direction, they have been successfully overcome. It has taken a good time for the Imperial Cable to become known, especially in our great provincial centres, but this state of things is gradually disappearing, and with the use among other things of our special delivery forms and envelopes, together with the forwarding forms showing the joint titles of the Imperial and Pacific Cable Board, it is hoped the system will soon get quite well known for what it surely is, a real, live Post Office cable concern.

A step in the right direction has recently been taken by the appointment of a number of canvassers both in London and the provinces. The good work of these officers has borne evident fruit. Our short cable experience has taught us that there is nothing like a little personal contact to remove a lot of the misapprehension which exists in business men's minds with regard to this "awful Post Office." At the same time, I must say that our clients have been kind. We are continually receiving testimonials as to our good work, and complimentary comparisons are frequently made, in spite of the fact that we always hold the scales evenly balanced.

It will be fresh in the memories of some that the Government has acquired Imperial Cable number two from the Direct United States Cable Company, primarily as an insurance against interruption of service. This cable runs from the terminus of the London-Irish line at Ballinskelligs Bay in south-west Ireland to Harbour Grace in Newfoundland, where it is relayed into Halifax. From thence communication is made to New York, through a cable to Rye Beach on the United States coast. It is believed to be the intention of the Department to bring this end of the cable out of Ballinskelligs, and extend it to our Penzance repeating office. This second Atlantic cable will greatly increase our capacity for transmission of traffic between the United Kingdom and the American continent. At present this cable continues to be leased to the Western Union Company on a short term agreement, subject to the right of the Post Office to take it over at any time in the event of the ex-German cable being interrupted.

The Pacific Cable Board also, is about to duplicate—partially at least—the Pacific section of the All Red Route. A much-needed provision for, on account of the great length of the link between Vancouver and Fanning, the rate of signalling is low and reduces the speed of the whole Pacific section to a very small figure. There is a good deal of traffic over this part of the route between Australasia and America and Canada, and the duplication will have a beneficial effect all round.

Who knows what the future may hold in regard to the extension of State-owned cables? Let these be what they may, I think we can confidently assert that the foundations of their working have been securely laid.

POST OFFICE SPECIAL CONSTABLES.

SPECIAL RESERVE.

ALTHOUGH their active functions came to an end a few weeks after the conclusion of the Armistice, it may be of interest to the readers of the *Telegraph and Telephone Journal* to learn something of the doings during the war of the Post Office special constables.

In view of the extreme importance of telegraph and telephone communications in war, it was essential to provide in every possible way for the security of the chief telegraph and telephone buildings. Accordingly, one of the precautions taken within a few days of the outbreak of war was the enrolment of volunteers from the Post Office staff as special constables for the protection of Post Office property. Fortunately, some of the dangers feared at the outset did not materialise, but the Zeppelin menace and, later, hostile aircrafts' visits, caused very great anxiety, arising not only from apprehension of direct damage from air bombs but also from the possibility of resultant fires. To meet these risks squads of Post Office special constables attended nightly at the principal postal telegraph and telephone buildings in the London Area. They were instructed carefully, among other things, in the use of fire-fighting appliances, and in the topography of the premises, a most important point in the case of such large buildings. There were very few raids on London during which damage was not caused to property in close proximity to Post Office premises. On the day when the Central Telegraph Office was bombed, there was an outbreak of fire which the Post Office special constables, who were standing by in readiness on the spot, helped to keep under pending the arrival of the fire brigade. On other occasions Post Office special constables stood by with fire hose ready to prevent fires spreading to Post Office buildings from conflagrations near by, and they extinguished one or two small fires caused by wind-borne flaming billets.

During the earlier raids and threats of raids, particularly before public warnings were instituted, the knowledge that special constables were stationed on the look-out was a help to the Post Office staff which remained at work. Even when public warnings were given, the presence of the constables was of considerable moral support, especially at Telephone Exchanges where female staffs were carrying on, under very trying conditions, their very important national work, including telephone services connected with the repelling and destruction of hostile aircraft.

When the Post Office buildings were made available as Air-Raid Shelters, the Post Office Special Constables undertook the task of marshalling and controlling refugees in Post Office premises.

The G.P.O. North, West and South and the King Edward Building were protected by Post Office Special Constables enrolled in the City of London Police Special Reserve. These numbered from first to last between 500 and 600.

Colonel W. T Reay (of the Metropolitan Police Reserve) in his recently published book: "The Specials: How they served London," wrote of the Post Office Division (Metropolitan Force) as follows:—

"Close upon two thousand of the staff were enrolled in the General Post Office Detachment of Special Constables, which was under the charge of Commander C. W. Masters Paterson, with Mr. E. A. Martin as Assistant-Commander. Both are capable men and were enthusiasts in the work. They had during the war an administrative office in Victoria Street, and day and night there was in attendance an inspector who, in a night emergency, took up the general direction of the Detachment until the arrival of a senior officer.

The largest unit was that formed at the administrative office (at Kensington) of the Post Office Savings Bank. The strength ranged from 150 to 200; the men were well organised and well drilled, and, although primarily their police duty was departmental, they were ready for outside work at a pinch. In the engineering and stores branches, at the district post offices, and at some of the telephone exchanges, units—forty-eight in all— were formed. The exchanges were very vulnerable points, and, of course, of incalculable value in all schemes for the defence of London. In anticipation of and during raids, the work they did was of the first importance. On the rare occasions when an exchange had, during the heat of a raid, temporarily to suspend activities, it made all the difference in the world to the men charged with defence and associated responsibility.

To insure police protection for the Exchanges when it was most needed was the privilege of the local body of special constables, and their work was marked by zeal, skill, and courage. Meanwhile, the other units did their parts at the more or less extensive establishments of the branches of the service to which they respectively belonged. Some of the District Post Office detachments were very well drilled.

The principal officers and a few of the men provided themselves with uniforms; but the great bulk were distinguished only by police armlets, supplemented in the case of officers by additional vari-coloured armlets indicative of rank, such as all officers of the Force wore before general service men were put into uniform. The Commander and his Assistant frequently inspected the units at their own respective centres, and on three occasions the General Post Office detachment turned out for a general inspection parade. The detachment won the praise of the successive Postmasters-General, that of the permanent chiefs of the service, and that of all who saw them.

Digitized by Google

At the valedictory parade of the Special Constabulary, the detachment marched past the King and, in default of uniform clothing, all appeared in straw hats."

Of the total Force mentioned by Colonel Reay, upwards of 600 came from the Engineering and Telephone branches of the service.

During the whole of the war period, from early in 1915 until the conclusion of the Armistice, nightly guards were maintained at all the buildings belonging to the Department, Savings Bank, Money Order Department, Stores Department Depots, L.P.S. District Offices (including the Inland Section, Mount Pleasant), and Telephone Exchanges. This necessitated the absence from home for the entire night on many occasions of the men on duty, thus contrasting with the outside specials on street duty who, as a rule, were only called upon for four hours spells in the neighbourhood of their own homes.

Six hundred and fifty-six men of the division qualified for the Special Constabulary Long Service Medal by three years' continuous service, combined with the performance of at least 150 turns of duty, representing at least 600 hours of voluntary and gratuitous work—exclusive of the time occupied in travelling to and from duty and the hours necessarily spent in the guard rooms when duties were completed at too late an hour to enable a return home to be made.

In addition to the actual Long Service Medal a large proportion of the constables earned the Long Service Badge for two years' continuous service and the Silver Star for enrolment prior to Dec. 31, 1914.

Col. Reay concludes his history in the following words :—

"We venture to claim that included, although not specifically mentioned, are the special constables of the metropolis and elsewhere in the thanks which Sir Douglas Haig, in his last despatch, gave to our kinsmen and kinswomen of the British Empire for the unfailing support they have given us by their thoughts, their prayers, and their work throughout the long years of war." "In all these years," he adds, "their trust and confidence never wavered, their labours never ceased, and no sacrifices, hardships, or privations were too great to be borne, provided that thereby the needs of the troops might adequately be supplied. The dauntless spirit of the people at home strengthened and sustained the invincible spirit of the Army."

WHAT THE SPECIAL CONSTABLE HAS GAINED.

There is, however, a debtor as well as a creditor side of the account with the community. We have not disguised our view that the men who served as special constables have well earned the thanks of their fellow-citizens. On their part these men are the first to acknowledge their gratitude for having been given the opportunity for service when their country was at war. Theirs was not the smug and unenviable placidity of the shirker. Nor did they hold in those terrible days of anguish, when it was no mere figure of speech to say that "never morning wore to evening but some heart did break," that it was sufficient for the non-combatant to give his tongue to the currency of unctuous moral sentiment. Mingled to-day with the proud satisfaction that they "did the State some service" is their clear recognition of the fact that the force organised and managed by Sir Edward Ward furnished them with a field and enabled them to do real work. The call which the war made to the citizenship was in the police, as in other useful services—alike in the more important and the less important—a call to England's higher patriotic sense. Some think that before this call that sense was in peril of the atrophy which is ever the penalty of disuse.

"Before the war," remarked the other day one of those concerned, "I suppose I figured amongst the people who, while discharging professional and family obligations, did little or nothing for the community. I came into the Special Constabulary, and it gave me more than I could ever give it—in knowledge, breadth of vision, real experience, neighbourly association with other men of all classes, and the ever-resultant admiration for them and a worth in them I had not previously known. So if I'm not a better man as the result of this service I ought to be."

The Post Office division did not expire with the War, but survives as a branch of the Special Constabulary Reserve under the leadership of its old Commander (now Commandant) C. W. Masters Paterson and has at present an enrolled strength of over 600.

The conditions of service provide that members of the Reserve will only be required to do duty when the Commissioner of Police deems it necessary to declare an emergency, and so far as the Post Office division is concerned their primary duty will be, as in the past, the protection of the property of the department. At the same time members will have the opportunity of volunteering for other duties such as helping the regular police to line the routes of Royal and other processions. Men joining the divisions will now be supplied with uniform—overcoat, tunic, trousers and cap.

The present strength of the Post Office division is unworthy of the department and of the splendid Force which existed during the war. It is hoped that many of the old members, "fed up" perhaps for a time on the conclusion of their strenuous duties, will again respond to the call and rejoin their old comrades, and that younger men, who have "done their bit" in the fighting services, and who have perhaps for the time being felt equally "fed up," will realise that the country still calls for their services as and when occasion arises, and see in the Special Constabulary Reserve an easy and honourable way of being on the spot and ready when national danger arises.

LONDON ENGINEERING DISTRICT NOTES.

Imperial Cable Communications.

Mr. Avery is to be congratulated on the admirable paper which he read on the above subject at a recent meeting of the Telephone and Telegraph Society, not only on account of the paper itself, but also because it was the means of drawing out some most interesting information from subsequent speakers. For example, Mr. Lack referred to the laying of a submarine cable from Peterhead to Alexandrovsk, by the Cable Ship *Colonia*, in the record period of eight days. The office at Alexandrovsk was subsequently destroyed by fire, due, it is believed, to enemy action. The members of the staff contrived, however, to salve a few pieces of apparatus and, in the course of two or three days, extemporised a signalling set which enabled them to make their requirements known to the British Authorities. The necessary apparatus, including an artificial line, was hastily manufactured in this country and despatched to Russia with the result that duplex working was quickly restored. Although the work was done at great speed it was well done, as is evidenced by the fact that, with the exception of one short stoppage due to a fault in the cable, the circuit has worked continuously to the present time. A cable was also laid from Alexandrovsk to Archangel with a repeater at a little village on the Murman coast named Yukanski. Mr. A. H. Roberts, of the Engineer-in Chief's office, went to Russia in connexion with these operations and had some unique experiences.

Mr. Avery's paper is published in this month's journal, but engineering readers will be interested to know that there are two repeater stations between London and Halifax, Nova Scotia, one being at Penzance and the other at Fayal in the Azores. The Dipper Relay is in use at Penzance for re-transmitting to London the signals received from the cable, and Post office relays are used for transmitting towards Halifax. At Fayal a drum relay is used on both sections of the cable for re-transmitting purposes, and an interpolator is introduced for the purpose of converting the received block signals into perfect signalling units. Currents are thus sent out which are similar in form to those sent out by the originating station. The installation at Halifax was supervised by Mr. James Lockhart, of the Engineer-in-Chief's office. Mr. Lockhart also visited Russia in connexion with the cable before mentioned.

When the Germans were making their first rush through Northern France a cable was laid from Beachy Head to St. Nazaire and was of immediate and almost priceless value. Mr. J. Fraser, of the Engineering Department, was in France in connexion with this work.

During the war period Post Office repeaters were installed by some of our colleagues at Dieppe and Havre. By these means it was possible to work Triple Duplex Baudot between London and Paris on the Beachy Head-Dieppe and Cuckmere-Havre cables.

If the work done by Post Office engineers in all parts of the world during the war period were properly described what an epic it would prove ?

Harrow New Exchange.

A new No. 10 C.B. Exchange was brought into use at Harrow on Wednesday, March 30, the transfer from the old No. 9 C.B. Exchange taking place at 2 p.m. on that date. The new exchange, which provides accommodation for 1,400 subscribers' lines, is housed in an extension of the old exchange premises. The installation was carried out by Siemens Bros., and, in common with the usual practice of this firm, is supplied with a 40-volt battery. The transfer was effected very smoothly and successfully, and much credit is due to the local staff. At 4 p.m. the subscribers' lines and junction circuits were entirely free from faults.

Hitherto it has been usual to carry out transfers to new exchanges on Saturday afternoon, but a departure from this procedure was made in the case of Harrow. Wednesday, being early closing day, was chosen in preference to the following Saturday, on which day a local election was to take place.

Private Branch Exchanges.

In spite of the slump in trade under which the country is suffering and the unsettled conditions obtaining at the present time, the Private Branch Exchange work in the district maintains a satisfactory level. Several new works are in hand and extensions to certain existing switchboards are being installed. A large No. 1 type exchange for an important Government department will probably mature in the near future and this, together with other cases which are under review, ensures a busy time for the large staff which has been engaged on this class of work for the past few years.

Telephone Repeater at Trunk Exchange.

Much has been said and written recently about the advantages which are expected to follow the introduction of telephone repeaters, and readers of these notes will be interested therefore to know that a repeater cord circuit has been in use for some weeks at the London Trunk Exchange on the Cardiff-Paris connections. Up to the present the experiment has been entirely successful. The improvement in speech is equal to the suppression of approximately 10 miles of standard cable.

A similar repeater will shortly be brought into use in connexion with the Liverpool-Paris traffic.

It is not possible to estimate, even approximately, the total financial gain that will accrue from the extensive use of repeaters, but there is no doubt that it will be very considerable and that any expenditure upon research work in this connexion will be amply repaid.

Digitized by Google

High Frequency Telephone Circuits.

When Sir William Noble read his paper before the Institution of Electrical Engineers reference was made to the experiments that had been carried out in America with High Frequency or "Carrier" Circuits. It may not be generally known that our own Research branch has for some months been making experiments with a similar system with a view to its adoption in a form suited to English conditions. Considerable progress has been made and there is reason to believe that a few circuits will soon be put into commercial use between London and Bristol. It is expected that ultimately it will be possible to have six or more conversations proceeding at the same time over one pair of wires without interference.

Wireless Telegraphy.

In the March issue reference was made to the large number of licences granted to members of the public. The number of permits issued now exceeds 1,000. The increase for the month of March was 67 stations.

Telegraphing to Germany.

A Siemens-Halske automatic type printing set has been fitted in the Foreign Gallery of the Central Telegraph Office for communication with Germany. With this apparatus it is possible to work duplex at high speed (160 words per minute), but this advantage is counter-balanced by the fact that the flexibility of the system is not so great as that of those worked on the Duplex Multiplex principle.

London Inspectors.

The London engineering inspectors held their first annual dinner at the Connaught Rooms, on April 4. Over one hundred members were present under the chairmanship of Mr. J. D. Boulton. After a presentation had been made to Mr. C. W. Messenger, Mr. H. B. Howe proposed the toast of "The Society." In responding the president stated that the membership exceeded 1,000. He made special reference to the benefits of Whitleyism, and predicted still greater success if all concerned invariably approached their tasks with an honest and open mind. The chairman then proposed the toast of "The London Engineering District," and gave statistics to show the great and increasing volume of work carried out, the varied nature of the work, and the degree to which the maintenance efficiency of the district had been improved since the date of the transfer. He coupled the toast with the name of Mr. A. Moir, Superintending Engineer, who was the guest of the evening. In reply, Mr. Moir expressed his deep appreciation of the kindly reception accorded to him. Whatever success had attended his management of the London District was due to the loyal and energetic help of the staff. Many of the inspectors before him were his own nominations, of which he thought he had a right to be proud—(Cheers). He might tell them that the one great attribute necessary for upward movement on the staff ladder was thoroughness. If they knew their job, were thorough and prompt, promotion was practically assured. Other toasts were "The Visitors" and "The Veterans of the Inspectors' Society."

A really enjoyable musical programme was provided during the evening.

Western Telephone Cricket Club.

A concert in aid of the above club was held at the Chiswick Town Hall, on Wednesday, March 30, organised by the committee (Mr. C. W. Stewart, Mr. W. Hole and Mr. E. R. Gray).

The musical part of the programme was arranged by Mr. F. Walker (Park Internal) and special thanks are due to him for his effort in this direction. An audience of 200 spent an enjoyable evening, appreciating very much the talent of the various artistes. The interest of the executive officers of this and other sections was demonstrated by the presence of Messrs. A. G. Cardrey, R. Wilson, J. A. Hunt, J. L. Brown, W. J. Gear, E. P. Neate and H. M. Chambers.

It was originally intended that the proceeds should be devoted to a fund for inaugurating a sports club to replace the existing cricket club, but unfortunately it has not been possible to obtain a suitable sports ground for this season. The cricket club has now been in existence a number of years, and it is thought that the time is ripe for extending its sphere by the formation of a General Sports Club. If the necessary support is forthcoming, it is hoped to make arrangements for the renting of a ground for next season, and with this object in view another concert will be held in the autumn. The committee will be glad of any assistance readers may be able to offer.

All communications should be addressed to the Hon. Sec., Mr. E. R. Gray, at Park Exchange.

Denman Chess Club.

A most successful first season was brought to a close on Wednesday, March 30. The club championship has been won by Mr. Francis, but the tournament has not yet been finished.

It is hoped that the membership roll will be considerably extended next season.

One of the club members, Mr. R. A. Wells, who is also a member of the Engineering Department (Engineer-in-Chief's) Chess Club, has won the championship of the latter.

THE STRIKE PRESSURE AT THE C.T.O.

ONCE more the Central Telegraph Office has been called upon to face abnormal pressure as a result of labour troubles and a period of unwelcome comparative slackness has suddenly been transformed into one of exceptional stress. Although the volume of work was not so great as at the commencement of the Railway strike of 1919 the recent situation has in some respects been more difficult to deal with as the uncertainty of the position from day to day and even from hour to hour, and the sudden and dramatic nature of the changes made it an extremely difficult matter to estimate requirements and to make advance arrangements to meet emergencies.

The decision of the Railwaymen and Transport Workers to strike at midnight on Tuesday, April 12, led to a large increase of general business during the week preceding that date and the mobilisation of the Navy and Army Reserves brought with it much Government traffic. Continuous telegraphic facilities were provided to all the large Naval and Military centres, and in a modified degree the conditions were reminiscent of the early days of the War. Up to Saturday the strike appeared to be inevitable, but hopes of a settlement were raised by the receipt about 9 p.m. of a request for arrangements to be made for the immediate delivery of urgent telegrams to a large number of addresses in mining districts. As all offices except the head offices in the very largest towns were closed at that hour it was necessary to advise those which were open to be prepared for the messages and to arrange for their disposal by any means available.

In view of possible developments it was decided on Sunday morning that all offices then open till 10 a.m. in normal course should re-open at 5 p.m., and although there were no changes of importance during the day the additional outlets were very welcome as the evening work, especially Government traffic, was heavy. Matters quieted down after the postponement of the Railway and Transport Workers' strike on the Monday, but revived on the announcement that it was to take place at 10 p.m. on the following Friday. Right up to 4 p.m. on that day there was every indication that the strike would take place, but at that hour news came through that it was to be cancelled and for the rest of the evening the office was flooded with work. Batches varying from 50 to 1,500 messages in each batch came to hand in quick succession.

A feature of the traffic throughout the crisis was the large amount of "batch" work including one batch of 3,000 messages in connexion with the postponement of the Census arrangements. These batches usually consisted of a list of addresses and a text, and as this entailed the preparation of a separate complete form for each address the work involved, apart from the actual signalling operations, can readily be imagined.

Arrangements had been made with the object of securing the attendance of the staff in the event of a stoppage of travelling facilities, and detailed instructions to the staff were in readiness for distribution, but it was decided to run some risks and to defer the introduction of the emergency arrangements until the last possible moment. As events turned out this avoidance of any precipitate action was fully justified and much expense and dislocation of normal arrangements were avoided.

It is satisfactory to be able to say that without departing to any appreciable extent from the ordinary course an excellent service was maintained throughout the crisis, and there were very few instances of anything approaching abnormal delay. As usual the staff rose to the occasion and it was due to their efforts and to the cordial co-operation of all ranks that the work was dealt with so smoothly and expeditiously.

PRESENTATION TO MR. J. T. WHITELAW, DISTRICT MANAGER, MIDDLESBROUGH.

A large gathering of the District Office Staff, Middlesbrough, met on March 9 to make a presentation to Mr. J. T. Whitelaw on the occasion of his promotion to Rochdale. Mr. T. Hann, Chief Clerk, in making the presentation on behalf of the staff, spoke in appreciative terms of Mr. Whitelaw's career in the Middlesbrough District and expressed congratulatory sentiments on his promotion. Mr. W. Brodie, Contract Manager, Mr. W. A. Frame, Assistant Traffic Superintendent, and Mr Ford, Postmaster of Middlesbrough, also contributed complimentary remarks. Mr. Whitelaw feelingly replied and thanked the staff for their co-operation and kindness during his term of office at Middlesbrough. The Staff's gifts were a silver-mounted ebony walking-stick and silver cigarette case, together with a pair of silver vases for Mrs. Whitelaw. An enjoyable programme of songs, whist, etc., concluded the proceedings.

LONDON TELEPHONE SERVICE NOTES.

AFTER a period during which so much adverse criticism has been levelled against administration by Civil Servants, and especially the administration of the telephone system, the following extract from an article in the *Daily Telegraph* concerning the Food Ministry provides a welcome contrast in its tribute to Civil Servants generally :—

> "It is impossible to form a true conception of the work involved in buying such gargantuan stores of food as these statistics represent, and then distributing them in small quantities to millions of consumers so as to ensure the fair treatment of everyone in the matter of amount and price. For the triumph achieved, the successive Ministers, in accordance with our well-established ideas of public life, deserve the credit, as they would have received the blame had they failed; they were supported by the advice of business men of knowledge and experience, to whom praise is also due. But the efficient administrative structure, with its widespread ramifications at home as well as abroad, could never have been created without the trained skill of the Civil Servants who were associated with the Ministry. They saved it from chaotic confusion. They translated into action the policy of the Government as reflected by the Minister from time to time. It has become the fashion in some quarters to sneer at Civil Servants, but let it be said that no community is as well served in this respect as our own. The British Civil Service, with its high traditions, has no superior, and no little of the success of the Ministry of Food as of other war Ministries, was due to the members of this great silent body."

* * * *

That happy home of telephones which our critics would have us believe exists on the other side of the Atlantic is, we learn, disturbed by a revision of telephone tariffs. In fact one of the news agencies reports that "considerable disgust" has been raised in New York by the decision to increase the rates by 28 per cent. Increased salaries and other expenses are urged as necessitating the change.

Harrow Exchange.

Wednesday, March 30, saw the opening of the new Harrow Exchange. The new switchroom, which forms a new wing to the old exchange building, had been in readiness for some years, but the equipment was deferred owing to the war.

The date selected for the transfer was unusual. Advantage was taken of the anticipated slackness of traffic on the early closing day, instead of deferring the transfer until the usual week-end, when, on this occasion, the excitement of a local election was calculated to increase the normal Saturday traffic. Owing to an outbreak of influenza, the School, due to break up on the intervening Friday, was closed three days earlier, and the day of transfer saw a pressure of traffic considerably greater than usual. In spite of such adverse circumstances the transfer of the 700 subscribers' lines and 140 junctions took place without hitch and is recorded as being one of the most successful, thanks to the efforts of the Traffic and Engineering staffs.

The new exchange is of the C.B. No. 10 type, having lamp signals which are much preferred to the indicators of the old C.B. 9 board by the staff. The subscribers' multiple has a six-panel repetition throughout instead of the standard four-panel repeat. This modification was decided upon when it was found that the ultimate development of Harrow subscribers would exceed the estimated capacity of 2,000, on which the four-panel repetition was designed. The incoming junction equipment is jack ended instead of the usual plug ended, and Harrow possesses the distinction of being the only C.B. 10 exchange in London whose incoming service is carried by the new and much-debated jack ended type of junction. The new board is fitted with subscribers' registers. The capacity of the initial equipment is for 1,400 lines and the 700 spares will, it is confidently expected, be absorbed within five or six years.

The old switchroom, when cleared of telephone apparatus, will be utilised as a telegraph instrument room for the Harrow Post Office which forms the other wing of the building.

Langham Choral Society.

The last concert of the session will take place at 8 p.m. on May 10 at Queen's Hall. An attractive programme consisting of operatic excerpts and a concert performance of "Cavalleria Rusticana" has been arranged, with Beatrice Miranda, William Boland and Andrew Shanks as soloists.

Tickets, prices 8*s.* 6*d.* to 2*s.* 4*d.*, are on sale at all exchanges, or can be obtained from the Hon. Secretary, Miss W. M. Nurse, West Traffic Office, 11 12, Norwich Street, Fetter Lane, E.C.4.

Coming Events.

A new feature of our JOURNAL will be the inclusion in each issue of a diary of events taking place during the ensuing month. Exchanges are invited to announce in that column any social or other functions which they arrange. The items should be sent not later than the 15th of each month to Mr. Mead, Traffic Branch, 32, St. Bride Street, E.C.4. The period covered by the diary will be that from the 10th of the month of issue to the 10th of the following month. Thus items sent in by May 15 will appear in the June issue, and should cover the period June 10 to July 10. It is hoped that all exchanges will make full use of this column.

L.T.S. Whitley Committee.

The subjects dealt with at the tenth meeting of the L.T.S. Whitley Committee included the extension of the tea relief on 10-hour duties, the provision of metal lockers in the exchanges, accommodation for the medical officer and patients in the G.P.O. South building, the removal of the record table from the Trunk Exchange switchroom, and the desirability of arranging regular standing reliefs for telephonists. It was agreed to set up a special Committee with the following terms of reference: "To consider and make recommendations for improving the arrangements for cooking meals for night telephonists in the following exchanges in the L.T.S., Gerrard, Regent, Central, City and Trunks." The members of the Committee are :—

Official side.—Mr. Benham, Chairman, Mr. H. Dive, Miss R. James.

Staff side.—Misses A. M. Flanagan and D. J. Curtis, Messrs. Lansbury and Campbell.

Operating Statistics.

A statement was made concerning the improvement which had occurred in the Service as shown by a comparison of the operating statistics for the six months ending December, 1920, with similar statistics during and before the war. The figures in question are :—

	Six months ending June, 1914.	Six months ending Dec., 1919.	Six months ending Dec., 1920.
Percentage of "cut off" cases ...	.6%	.72%	.56%
		Ending June, 1919.	
Percentage of wrong numbers ...	3.5%	4.7%	4%
		Ending Dec., 1918.	
Percentage of operating irregularities	29.2%	36.2%	26.3%
		Ending June, 1919.	
Average time taken by operator to answer	4.8 secs.	10.1 secs.	5.9 secs.
		Ending June, 1919.	
Average number of written complaints per 1,000 direct lines per working day	.86	.92	.47

PRESENTATION TO MR. TINSON.

A presentation to Mr. Tinson, Assistant Superintendent and Head Master of the C.T.O. Telegraph School, on his retirement from the above honorable post and official life, took place on Thursday, March 31. Kindly was the thought that prompted this friendly gathering, the ladies—as usual the soul and animating spirit of this celebration—surpassing themselves, not only with their songs and elocutionary efforts, but also in the perfection of their refreshment arrangements.

The Deputy-Controller made the presentation in a brief speech, which admirably placed on record the affectionate tribute of a friend of over 35 years' standing and aptly expressed the goodwill of those present.

Mr. Tinson made a really happy response to the generous remarks and and was evidently deeply moved.

The opportunity is now taken of placing on record on behalf of the school staff who have been closely associated with him in his labours, the positive pain with which they part from so real a friend. They will always carry with them a fragrant memory of his personality. His presence was always cheering as a shaft of sunshine, while his abiding interest in his staff and in the young pupils committed to his care was ever marked by thoughtful and even affectionate kindness.

It is unavoidable to omit one of the delightful surprises of the evening which was the singularly effective speech of *our* Controller. All knew that Mr. Lee had a wonderful way with him, but the manner in which he said what he had to say was as striking as a new revelation. It was a remarkably happy blend of elegance and good sense enlivened and illumined by many a playful and imaginative sally. Even a verbatim report would convey but a very imperfect idea of its witchery, and the effort crowned a very happy and successful evening with yet another crown of success. Mr. Tinson should be a happy man.

DENMAN STREET AND ITS SURROUNDINGS.

By F. W. HEATH.

THE spacious building in Denman Street, London Bridge, which forms the headquarters of the London Engineering District, formally opened in June, 1916, by the Postmaster-General, stands upon grounds formerly occupied by St. Thomas's Hospital, which was founded by Richard, Prior of Bermondsey, in 1213, and under various forms continued to exist until its removal to its present situation on the banks of the Thames, on the East side of Westminster Bridge, in 1870-71.

As the Borough High Street and Old London Bridge were for many centuries the only avenues of approach into London from the South of England, and indeed from the Continent, the neighbourhood was always a busy and bustling one, and many a brave pageant and historical event have taken place within a few yards of the present office buildings.

Across the High Street lies Southwark Cathedral, known to former generations first as St. Mary Overy's and later as St. Saviour's. Here memories of the great dead thickly crowd upon us. Shakespeare, it is known, resided in the neighbourhood in 1596, and Malone says: "Nor is there any ground for supposing that he ceased to reside there until he quitted the stage altogether." The Revd. Canon Thompson styles him "Our most distinguished parishioner," and goes on to say "Without the smallest desire to deprive Stratford-on-Avon of a particle of the high honour which it proudly enjoys as the birthplace of Shakespeare, we should like it to be remembered that he belongs most truly to London, and especially to St. Saviour's, where he spent the best, if not the greater part of his days, and where his mightiest work was done." In the Cathedral is a beautiful window in his honour. His youngest brother, Edmund, was buried here Dec. 31, 1607.

Here lie also buried, Gower, the father of English Poetry, and Fletcher and Massinger, the Playwrights. John Harvard, the founder of the University bearing his name at Cambridge, Mass., was born almost under the shadow of the Cathedral walls, and was baptized here Nov. 29, 1607.

The Church of St. Thomas at the rear of the office in St. Thomas Street is used as the Chapter House of the Cathedral, and was acquired for that purpose in 1901. It was rebuilt in 1702 on the foundations of the monastery.

Passing westward we reach New Park Street, formerly Maid Lane, upon the site of Shakespeare's own Theatre, the "Globe." This fact is made known and the position approximately indicated by a tablet upon the wall of Messrs. Barclay and Perkins's brewery. It was built about 1599 and burnt June 29, 1613. The neighbourhood of Bankside was then practically the playground of London, and here, as well as the "Globe," were other theatres and the Bear Garden. Edward Alleyn, the celebrated actor and founder of Dulwich College, enjoyed the post of Keeper of the King's Wild Beasts, or Master of the Royal Bear Garden, Southwark.

In the Borough High Street stands the old "George" Inn; notable as being the last of the old coaching houses. "The Tabard," from which pilgrims bound for the Shrine of St. Thomas à Becket used to set forth, as recorded by Chaucer in the "Canterbury Tales," "The White Hart" where Mr Pickwick first met Sam Weller, the "King's Head," the "Queen's Head," the "Bull," the "Spurre," have all gone, but the "George" survives in much the same condition as in the days when all who fared toward Dover had to do so by road. True there is an inn called the "Tabard," but it is a very modern affair. As long ago as 1676 the then standing house was burnt, and it is doubtful whether even then any part of the building was co-existent with the time of Chaucer.

But the Borough, as well as for its inns, was also noted for other places of resort; for there here existed, or in the neighbourhood, five prisons. The Marshalsea, a few of whose old buildings still exist a little to the north of St. George's Church, and in which many of the scenes of Dickens's "Little Dorritt" are laid, the Clink at Bankside, the Borough Compter, the site of which is now fixed by Counter Court, the Queen's Bench in the Borough Road, and Horsemonger Lane in the thoroughfare of that name, afterwards Union Road. It is good to think that these have all vanished, the last named being also the last to go, about forty years ago.

The district known as the Mint, which took its name from a mint established there by Henry VIII, which is now intersected by Marshalsea Road, was in its day an asylum or sanctuary for the lower class of debtors, coiners, and vagabonds of every kind. It flourished from the middle of the 16th Century and was not finally suppressed until the reign of George 1. It was here that the first case of Asiatic cholera in the Metropolis appeared in the great visitation of 1832.

Southwark Fair, which in Hogarth's time lasted 14 days, was held between where the Town Hall used to stand and Mint Street. Both Pepys and Evelyn mention it in their diaries. It was suppressed in 1763.

It must be a source not only of pleasure but of pride to the staff to know that their working lives at Denman Street are spent near the scenes of such great happenings, and in such a close association with a glorious past.

MY TRIP TO AMERICA, 1920.

By C. S. CLIST.

MY holiday this year was spent in Seattle, Washington, U.S.A., and it has been suggested that I should relate some of my experiences. I sailed from Liverpool on June 2 on the *Empress of France*. The weather during the first part of the voyage was not good, but I quite enjoyed life on board. We arrived at Quebec the following Wednesday morning, June 9, and great excitement prevailed when the boat was getting near land. I had passed the Customs, &c., and was on the train to Montreal by 2.30 p.m. The trains are much longer than ours, and I was impressed by the lack of platforms. One boards the train by the steps. I arrived at Montreal early in the evening, had a few hours there, then took the night train down to Toronto. That was my first experience of a sleeper. I wondered if I should sleep, but it speaks for itself that I had to be called in the morning.

I spent three days in Toronto, during which time I saw Niagara Falls, and left Toronto on Saturday, June 12, by the night train for the West, and arrived at Vancouver the following Wednesday morning. The time spent in the train is very interesting, as the scenery varies so much. From Toronto to Winnipeg reminds one of Scotch scenery, while from Winnipeg to Calgary is nearly all prairie. Calgary to Vancouver is just grand, the Canadian Pacific Railway takes one right through the Rockies. Food on the train is very good, and by the end of the journey one gets quite fond of the nigger porter. My brother met me at Vancouver and then my troubles of travelling alone were at an end, not that I had really experienced any difficulty on the whole journey.

I was sorry to leave Vancouver, but we had to continue our journey to Seattle early the next morning. We performed the journey of about 200 miles by motor.

It was a wonderful ride and gave me a very good idea of the country in British Columbia. We arrived at Seattle in the evening, and it took me quite a time to realise that I was at my journey's end.

Seattle itself is a charming place on the Puget Sound. On the one side is the Cascade Range, and on the other the Olympics. The town is built partly on the shores of Lake Washington and Lake Union. Both are very large, Lake Washington being about 30 miles long. The scenery, with the Sound and the mountains, is beyond my description, and I think it is one of the prettiest places along the west coast.

I had nearly eight weeks in Seattle, during which time I motored over 5,000 miles, so I have a good idea of the State of Washington.

I spent one morning going over the "Elliott" Telephone Exchange, owned by the Pacific Coast Telegraph and Telephone Company. The Exchange looked very much like one of ours. The expressions used are very similar to those we have. One they have sounds fine. "I beg your pardon" is always used if a wrong number is repeated or given. I had occasion to use the telephone a fair amount during my stay, and owing to my English accent, the poor American operator had difficulty in understanding me. The method of giving in the numbers differs a little from that adopted in this country; for instance, if three two double three were asked for, the operator would repeat, three two three three. The testing position is known as the hospital.

No educational exam. is required of the operators before entering the service of the company, and no medical test is enforced. The telephonist is questioned by the teacher in the school, when she calls for the form of application. I happened to be in the room when an applicant called, and to my great surprise, she was asked, "Are your eyes good?" "Can you hear all right?" "What about your throat? &c." It seemed very strange to me after our severe medical test. Promotion in the main part is given on merit. It may happen that the supervisor is far junior to the operator. The operators are trained for a week and then sent out to an exchange. Life generally is much the same as in our service, but discipline is more as we had it during the years of 1910-1914.

In July I visited Victoria, British Columbia, about five hours' boat trip from Seattle. It is a very pretty place and reminds one of England as regards customs, &c. As stated previously I had about eight weeks in Seattle. I left Seattle on Sunday morning, Aug. 15. The following Wednesday I arrived at Chicago where some friends met me and took me round to see the sights, including Lake Michigan. I left Chicago the same evening by the Pennsylvania Line, and was due in New York the next evening at 5.30. I travelled on the "time limited" express by which one pays six dollars extra, and if it happens that the train is late, so much per hour is returned. On this occasion the train was not late. We reached New York just at 5.30, and I spent the next day in seeing what I could of the city. It is certainly a very busy place, and the noise seems greater than in London, which, I imagine, is due to the overhead railways.

I left New York the next morning on the *Caronia* and arrived at Liverpool on Sunday evening, Aug. 29, just managed the night train to London, and reached Euston at 5.30 in the morning. I then realised that my holiday was really over, and must admit I was not pleased.

I like the West of America very much; the customs of the East are very different from those of the West. The scenery is also much grander on the other side. I can strongly recommend a holiday in the United States, and it is a good plan to go *via* Canada and return by America.

CORRESPONDENCE.

TECHNICAL PAMPHLET F.1.

TO THE EDITOR OF "THE TELEGRAPH AND TELEPHONE JOURNAL."

SIR,—With reference to the Technical Pamphlets now being issued to workmen, it may be desirable to call attention to a slight error in Pamphlet F.1, Fig. 9, Page 12, "C.B. sub's telephone, with wall sockets and plug." A fitter unless experienced, working to diagram, would possibly have some trouble owing to this omission.

On reference to Position 2, in the diagram mentioned, and tracing the ringing current from the Exchange B. line, it will be seen that the 1,000 w. extension bell is not provided with a return path, back to the Exchange B. line.

Whilst on the subject of Technical Pamphlets I. with many other fitters, wish to inquire if Pamphlets other than those issued can be obtained by purchase. We should like to see Groups D. E. and F. issued free and facilities provided to purchase any others desired.

"CIRCUITS."

[The "return path" our correspondent speaks of is provided by a strap shown in position 3. It is thought that the diagram is sufficiently explicit for most fitters, but as it is apparently liable to be misunderstood, a short explanatory note we understand from the Engineer-in-Chief will be added on next reprint.

An edition of the pamphlets for sale is now being prepared, and it is hoped that they will be available for purchase from the usual Government Stationers within the course of a few weeks.—ED., *T. & T. J.*]

DINNER TO MR. A. K. MURRAY, BIRMINGHAM.

Mr. A. K. Murray, Contract Manager, Birmingham, was invited by the Contract staff to a complimentary dinner to celebrate the 25th anniversary of his entry into the Telephone Service.

In proposing the toast of the guest, the Chairman, Mr. J. S. Rhodes, stated that Mr. Murray entered the Telephone Service at Glasgow on March 9, 1896; was made Contract Manager at Hull in 1907, and subsequently transferred to Birmingham in the same capacity in 1914. Mr. Murray, in his reply, specially mentioned the friendly spirit existing in the Department, and his remarks in accepting the gift of a set of golf clubs as a memento of the occasion, exemplified the fact that Scottish humour was not dead. Among the notable features of an exceedingly pleasant evening was a humorous topical song specially composed for the occasion.

CALENDAR OF COMING EVENTS.

May 10.—Concert of Langham Choral Society at Queen's Hall, 8 p.m.
„ 10.—Cricket. Cable Room *v.* D. and E. (C.T.O.) Dulwich Park.
„ 17.— „ Cable Room *v.* Met. (C.T.O.) Dulwich Park.
„ 24.— „ Cable Room *v.* A. and B. (C.T.O.) Dulwich Park.
„ 25.— „ Secretary's office (G.P.O.) *v.* Harrow P.O. at Roxeth.
„ 31.— „ Cable Room *v.* C. and F. (C.T.O.) Dulwich Park.
„ 27.—Annual Dinner of the Society of Civil Servants at Connaught Rooms (Sir Cecil Harcourt Smith will be in the chair and the Right Hon. D. Lloyd George will be present).

PERSONALIA.

LONDON TELEPHONE SERVICE.

Miss G. W. PORTER has been promoted Assistant Supervisor, Class II, at Brixton Exchange.

Miss D. APPLEBY has been promoted Assistant Supervisor, Class II, at Regent Exchange.

Miss F. I. CLARK has been promoted Assistant Supervisor, Class II, at City Exchange.

Miss L. A. FISHER has been promoted Assistant Supervisor, Class II, at Holborn Exchange.

Miss H. E. BLAKE has been promoted Assistant Supervisor, Class II, at Hop Exchange.

Miss M. E. CARPENTER has been promoted Assistant Supervisor, Class II, at Battersea Exchange.

Miss M. A. TYLER has been promoted Assistant Supervisor, Class II, at Hop Exchange.

Miss H. C. STILL has been promoted Assistant Supervisor, Class II, at Holborn Exchange.

Miss L. K. DAVIES has been promoted Assistant Supervisor, Class II, at Trunk Exchange.

Miss M. A. CHORLEY has been promoted Assistant Supervisor, Class II, at Central Exchange.

The following resignations have taken place on account of marriage :—

Miss E. M. HATTON, Assistant Supervisor, Class II, of Putney Exchange.
Miss A. BRIDGE, Assistant Supervisor, Class II, of Paddington Exchange.
Miss B. EASTER, Telephonist, of Avenue Exchange.
Miss G. WEBBER, Telephonist, of Avenue Exchange.
Miss D. M. E. HANSFORD, Telephonist, of Avenue Exchange.
Miss L. E. WELCH, Telephonist, of Avenue Exchange.
Miss F. V. H. HARRIS, Telephonist, of Central Exchange
Miss L. M. ADAMSON, Telephonist, of Central Exchange.
Miss E. R. LLEWELLYN, Telephonist, of Central Exchange.
Miss R. E. GOULD, Telephonist, of Hammersmith Exchange.
Miss E. M. HALL, Telephonist, of the Trunk Exchange.
Miss C. M. WEEKES, Telephonist, of the Trunk Exchange.
Miss D. M. BUTT, Telephonist, of the Trunk Exchange.
Miss B. BONE, Telephonist, of the Trunk Exchange.
Miss L. PALMER, Telephonist, of East Exchange.
Miss F. S. MILLER, Telephonist, of East Exchange.
Miss G. E. CARTER, Telephonist, of Barnet Exchange.
Miss A. R. C. PAYNE, Telephonist, of Victoria Exchange.
Miss F. A. OCKENDEN, Telephonist, of Victoria Exchange.
Miss E. L. KEDDIE, Telephonist, of Victoria Exchange.

PROVINCIAL.

Mr. A. E. M. CAREY, Contract Manager, Plymouth, was presented by the District Managers and Exchange staffs with a silver cigarette case on the occasion of his transfer to Bristol on March 31, 1921.

Miss F. POLGREEN, Telephonist, Plymouth, resigned on April 2, 1921, on account of marriage and was the recipient of a set of stainless cutlery from her colleagues.

At Preston, on Friday, April 1, Mr. F. E. ADAMS was presented by his colleagues with a clock as a mark of their esteem on his being transferred to Plymouth as Contract Manager. The presentation was made by the District Manager, Mr. E. E. Stockens, who, in a few well-chosen words wished Mr. Adams success in his new undertaking.

Mr. Adams, who has taken a leading part in the Amateur Operatic Societies of Blackpool and has appeared on the concert platform regularly during his eleven years in the Preston district, replied with considerable emotion. He will long be remembered in the Preston district for his cheery disposition and a readiness at all times to assist in any entertainment for which his services were in great demand.

MODERN WIRELESS TELEGRAPHY AND TELEPHONY

BY F. ADDEY, B.Sc., M.I.E.E., FELLOW I.R.E.

(*Continued from page* 118).

Continuous Waves.

The earliest systems of electric wave wireless telegraphy used spark transmission, and consequently detached trains of damped waves were radiated. More recently, systems have been developed by which an unbroken train of waves, all of uniform amplitude, is radiated for the whole time during which the transmitting station is sending a dot or a dash. This is known as "continuous wave" transmission, or shortly, as "C.W.," and possesses marked advantages over the older spark transmission.

Interrupted Continuous Waves.

The apparatus used for the reception of spark transmission is, in general, not suitable for the reception of continuous wave signals. It is convenient, however, for a station using continuous waves to be able to communicate, when necessary, with a station arranged for the reception of spark signals. This can be done by breaking up the continuous train of waves into detached portions, so as to resemble the radiation from a spark station. Such a process is known as "interrupted continuous wave," (contracted to "I.C.W.")

Reception of Damped Waves.

The receiving station is provided with an aerial, which is generally similar to that at the transmitting station. The passage of the waves is usually indicated by a sound being produced in one, or more frequently, a pair of telephone receivers. It is, however, not possible to actuate the telephones by passing through their coils the alternating current set up in the aerial, because the frequency with which the current reverses is too great. For signals made with a wave-length of 600 metres—the normal wave-length used for commercial ship communication—the frequency is half-a-million complete oscillations per second. Even if the electrical and mechanical difficulties involved could be overcome, and the telephone diaphragms set into vibration at a frequency of this order, nothing would be heard, because the frequency of the sound waves produced would be far above the upper limit of audibility. Some other method has therefore to be employed.

The type of detector used depends on whether spark signals or continuous waves have to be received. In the case of the reception of spark signals, some device is generally used by which the currents in the aerial in one direction only are allowed to act on the telephones, the effect of the currents in the opposite direction being suppressed. Such a device is called a "rectifier." The very short uni-directional current pulses so obtained from each wave-train are caused to blend together to produce a single pulse of current through the telephones, lasting as long as the train of waves is passing. As is well known, a pulse of current flowing through a telephone receiver produces a click. The passage of each train of waves will therefore be indicated by a click in the telephones, and a succession of such trains of waves by a series of clicks. Since a train of waves is sent out for each spark which occurs at the transmitting station, the clicks heard at the receiving station will correspond exactly to the sparks at the transmitting station. If these sparks occur irregularly the succession of clicks will also be irregular, and a rough sound will be produced, but if the sparks follow one another at equal time intervals the clicks will do the same, and will blend together to produce a musical note. The pitch of this note will depend on the number of clicks per second, and therefore on the spark frequency.

The various steps in the process are shown diagrammatically in Fig. 6.

The difference between (*b*) and (*c*) in Fig. 6 should be noticed. In (*b*) we have a picture of a section across the trains of waves, showing how, at a certain instant, the waves are spaced out along their line of propagation. In (*c*) we have a diagram showing how the currents in the aerial vary as the waves shown in (*b*) sweep across the aerial. In (*b*) the waves are to be imagined as moving

Digitized by Google

from right to left, while (*c*) has to be read from left to right, the direction in which time, the horizontal scale, is supposed to increase. (*a*), (*d*) and (*e*) are similar to (*c*) in this respect.

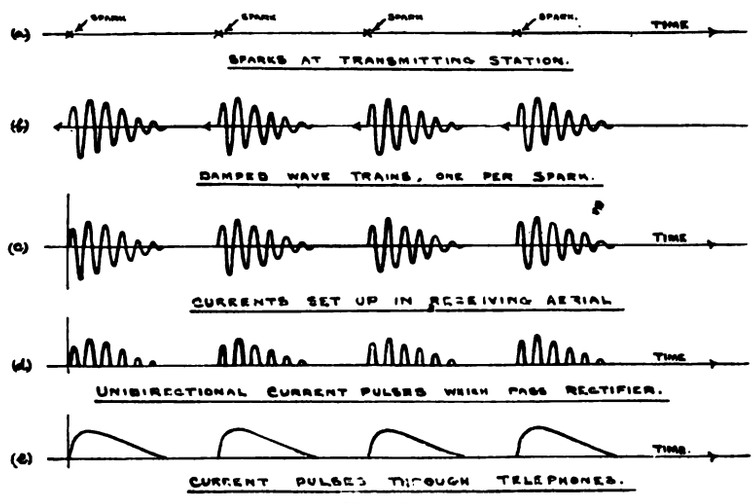

FIG. 6.

DIAGRAM ILLUSTRATING STEPS IN THE RECEPTION OF SPARK SIGNALS.

Reception of Continuous Waves.

If the rectifying arrangement just described were to be used for the reception of continuous wave signals, it is evident, since the waves are perfectly uniform, that a steady current would flow through the telephones during the whole of a dot or a dash. Now, a current produces no sound at all in a telephone while it is flowing steadily, its only audible effect being the production of a click when it commences to flow and of another click when it stops. Thus, if continuous wave signals were to be sent to a station fitted with a rectifier for spark reception, the only effect produced would be a series of meaningless clicks. For the reception of continuous waves, therefore, some other arrangement is necessary.

The method generally used is based on the well-known phenomenon of the "beats" produced by the inter-action of two oscillations which differ slightly in frequency. If two organ pipes which differ slightly in pitch be sounded together, the two trains of sound waves given off, which consist of alternate compressions and rarefactions of the air, will alternately assist and oppose one another in their effect on the drum of the ear, and so the intensity of the sound will rise and fall, thus producing the beats. That this will be the case can be seen from the section of the two trains of waves shown diagrammatically in Fig. 7. In this diagram (*a*) and (*b*) represent the two separate wave trains. (*c*) represents the effect produced when the two trains of waves (*a*) and (*b*) are produced simultaneously. The lines AA have been drawn across the diagram at the points where the two wave trains come into exact step. The line B has been drawn at the point where the waves are exactly out of step. It can be proved that the number of beats heard per second is equal to the difference between the frequencies of the two trains of waves.

In the same manner, if we are using continuous waves having a wave-length of, say 3,000 metres, which corresponds to a frequency of 100,000 oscillations per second, a steady alternating current of this frequency will be set up in the receiving aerial. If now, by some means, we generate at the receiving station a continuous alternating current of a frequency of 100,500 oscillations per second, or of 99,500 oscillations per second, and superimpose this current on the current of 100,000 frequency set up by the incoming signal, we shall get a beating effect produced as the two currents alternately come into exact step with one another and then get exactly out of step with one another. The frequency of the beats will be equal to the difference between the frequencies of the two currents and will thus be 500 per second. By suitable means these current beats can be caused to affect the telephones, and a musical note will be heard of a pitch corresponding to their frequency. For a frequency of 500 per second the note heard will be about the treble C.

Wireless Telephony.

It has been mentioned above that, in order to enable a continuous wave transmitting station to communicate with a station arranged for spark reception, the steady emission of the continuous waves has to be broken up into short portions so as to resemble the series of short detached wave trains emitted by a spark transmitting station. By an extension of this principle of moulding the emission from a continuous wave station it is possible to transmit actual speech.

The broad principle of telephony, wireless or otherwise, is as follows. In ordinary speech, the words are conveyed directly from speaker to hearer by sound waves of complicated form set up by the vocal organs. In telephony, the diaphragm of the transmitter is set into vibration by the speech waves. By the action of the transmitter these vibrations are caused to set up current pulses of similar form, and these current pulses, by the intermediary of either a telephone line or of free ether waves, cause the diaphragm of the telephone receiver at the other end to vibrate similarly to the diaphragm of the transmitter, and so to mould the air in front of it into sound waves, similar to those of the speech which originally started the train of operations. The sound waves produced by the telephone receiver affect the ear of the listener just as if they had come straight from the speaker, and had not undergone all the various transformations mentioned.

In wireless telephony a telephone transmitter is associated with the continuous wave generating apparatus, and when spoken into causes the amplitude of the electric waves given off to be moulded or "modulated" so that the line joining the tops of the waves, when these are represented in the usual diagrammatic manner by means of a wavy line, takes the shape of the curve representing the sound waves of the speech, as shown in Fig. 8 (*a*), (*b*), and (*c*), In practice the frequency of the wireless waves would be much greater relatively to that of the sound waves than is shown in the

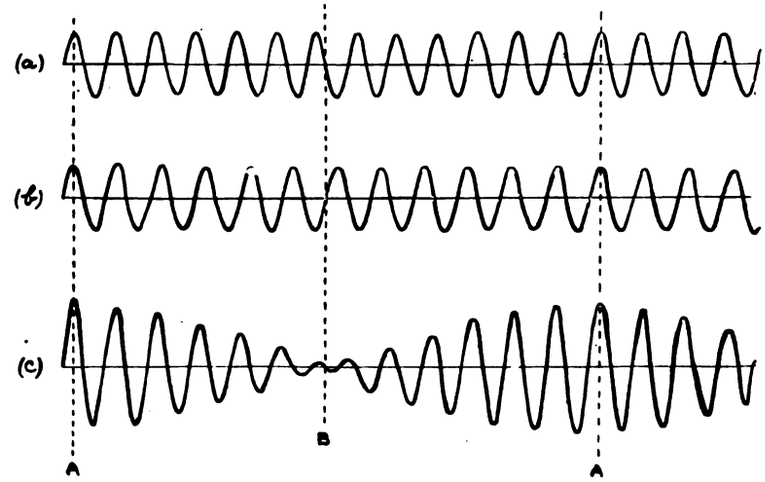

FIG. 7.

BEATS CAUSED BY THE SUPERPOSITION OF TWO WAVE TRAINS OF DIFFERENT FREQUENCY.

diagram, so that the very small ripples in the speech waves are impressed on the wireless waves. These moulded C.W. waves, as they pass the receiving station, set up oscillating currents in the aerial at that station, the amplitude of which varies in exactly the same manner as the amplitude of the waves. Fig. 8 (*c*), may therefore also be taken as a diagrammatic representation of the currents in the receiving aerial, the horizontal line being now taken as a scale of time, and the diagram read from left to right, as already explained in connexion with Fig. 6 (*b*) and (*c*). These oscillatory currents are detected at the receiving station by a rectifying detector, which, as already explained, allows the current pulses in one direction

Digitized by Google

only to pass. In Fig. 8 (*d*), the current pulses corresponding to the portions of the curve below the zero line in (*c*) are supposed to be suppressed. The current pulses which pass the rectifier are caused to blend together and produce a comparatively slowly varying current which varies in exactly the same way as the amplitude of the C.W. waves, and therefore reproduces the form of the speech waves, Fig. 8 (*e*). This current is sent through the receiving

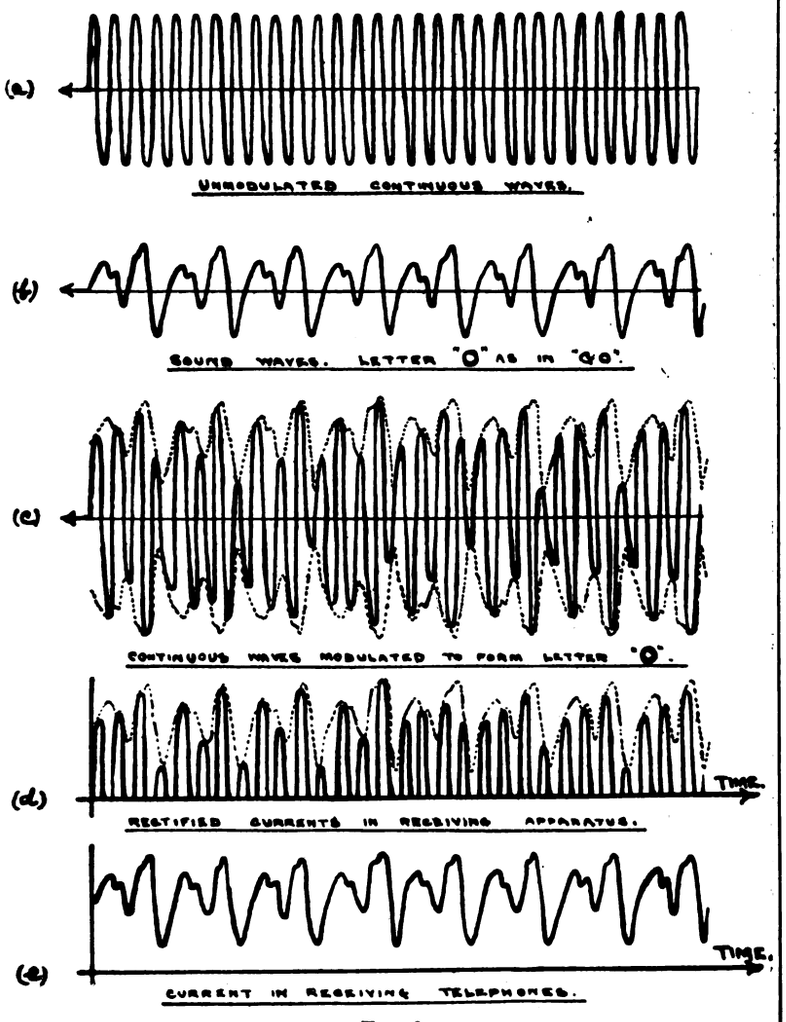

FIG. 8.

DIAGRAM ILLUSTRATING THE STEPS IN THE WIRELESS TRANSMISSION OF SPEECH.

telephones, and their diaphragms are therefore set into vibration and produce sound waves of exactly the same form as the speech waves at the transmitting station.

High Speed Transmission.

In most wireless stations the signals are transmitted by hand at speeds of about 20 or 25 words per minute. For an amount of traffic greater than can be handled at this speed, however, automatic transmission and reception are necessary. It is at present possible to carry on a more or less successful commercial service at speeds up to about 150 words per minute, and considerably higher speeds have been obtained experimentally.

Directional Working.

It has been explained above that at a wireless station fitted with an aerial which is symmetrical with regard to the earth, and where the nature of the surface of the earth round the station is uniform, signals will be sent out equally in all directions. Under the same conditions the strength of the signals received from other stations will be equal, no matter in what direction from the receiving station these stations may lie, so long as the distances at which they are situated from the receiving station and the strength of the signals which they send out are the same. The aerial at the first station is then said to be "non-directional." If, however, an aerial which is not symmetrical with regard to the surface of the earth be used, then signals will be received better from stations in certain directions than from stations in other directions. Such an aerial is described as "directional." By suitable means, the direction from which signals are best received can be changed. In this way, by causing the line of best reception to swing round till the strength of the signals received from some other station is a maximum, the direction of that station can be ascertained. This process of "direction-finding" is extremely useful to ships for finding their position during foggy weather, when the ordinary navigation marks are obscured.

Duplex Working.

Another advantage of a directional aerial is that by its use a station can be arranged to receive signals from a distant station, while the signals from a transmitting station near at hand can be cut out. By the provision of a transmitting station and a separate receiving station arranged in this manner at each end of a line of wireless communication, it is possible to carry out "duplex" working, that is, to send messages in both directions simultaneously. The transmitting apparatus is worked from the receiving station by means of a telegraph wire between the two stations.

Automatic Calling Devices.

One of the most useful functions of wireless telegraphy is that by its aid a ship in distress can summon assistance from other vessels in her vicinity or from the shore. In order that full advantage can be taken of this power of summoning assistance, however, it is necessary that a continuous watch should be kept at every wireless station, both on board ship and on shore. At land wireless stations a continuous watch is maintained, but on a small tramp steamer, for example, on which only one operator is carried, the keeping of a continuous watch is not possible. By the provision of "watchers," men able to recognise the S.O.S. distress signal, this difficulty is partially removed, as on receipt of a distress call, the watcher can bring the trained operator to the instruments. Several automatic call devices have recently been designed, with the object of dispensing with the services of a watcher. It is possible for an automatic apparatus to be installed which will not only ring a bell when the S.O.S. or some other equivalent signal is received, but will also ring a bell when the distinguishing call letters of the ship are received, and will differentiate between the distress signal and the ship's call.

Some of these devices, however, have the drawback that they may be actuated by ordinary wireless signalling, and so give false distress calls, and also that they are of delicate construction and liable to become deranged. There is no doubt, though, that before long a thoroughly satisfactory automatic calling device will be produced.

Time Signals.

In order to find his position when at sea, the captain of a ship requires to know the correct time at the spot where he happens to be, the so-called "local time," and also the time at the same instant at Greenwich. By astronomical observations the local time can be found, and then if by some means the corresponding Greenwich time is known, the difference between the two gives the longitude of the ship. Further astronomical observations give the latitude, and thus the position of the ship is fixed.

Greenwich time is obtained by means of one or more chronometers which are carried in the ship, and which are checked whenever possible. Before the development of wireless telegraphy the checking of the chronometers could only be carried out at ports where time guns or other signals were installed, or by means of difficult astronomical observations. Nowadays, however, wireless time signals are sent out once or oftener daily from many of the large stations in different parts of the world, so that it is possible to obtain a daily check of the chronometers. The transmitting apparatus by means of which these signals are sent is controlled from the standard clock at a neighbouring astronomical observatory.

(*To be continued.*)

HISTORY OF THE ANGLO-CONTINENTAL TELEPHONE SERVICE.

ALTHOUGH the first telephone exchange in England was opened in 1879, and telegraphic communication with France had been enjoyed since 1851, the provision of telephone service to France did not receive practical consideration until 1889. Nevertheless, it must be remembered that the development of long-distance telephony was not much advanced in this country at that time. Trunk lines had existed between Leeds, Manchester and Liverpool since 1886, and Edinburgh and Glasgow since 1887. London had indeed been joined up with Brighton since 1884, but the main trunk line connecting London with Birmingham and the North was not completed until 1890, and communication between London and Scotland was not afforded until some years later.

In March, 1889, M. Coulon, the French Director of Posts and Telegraphs, when in London in connexion with negotiations for the purchase of the Submarine Company's telegraph cables, urged the introduction of telephonic communication between France and England, and Mr. Preece, the Chief Electrician of the Post Office reported that there was no electrical difficulty in giving effect to the proposal. On May 16 of the same year the French Administration suggested that telephonic experiments should be made on the Anglo-French telegraph cables. About this time an offer was made by a Belgian Syndicate (Van Rysselberghe's system) to provide the necessary Anglo-French circuits and to sell them to the respective Governments if they proved successful. The offer was refused, the Administrations being of the opinion that they were themselves competent to provide a satisfactory service between England and France. The enterprise was not undertaken without misgivings, however. According to a newspaper report, General Boulanger's visit to London in 1889 was said to be hampered by lack of telephonic communication. "This," said Mr. W. H. Preece in a report "shows that the wire would be used for other than legitimate commercial traffic, and raises a political question." And in a later report Mr. (afterwards Sir J. C.) Lamb, Assistant Secretary, said: "The operations of an agitator like Boulanger would be much facilitated by the possession of means of communication between the two capitals." The idea of limiting the Anglo-French lines to commercial traffic strikes oddly on those who have seen them limited to non-commercial traffic in times when government calls only were accounted strictly "legitimate" traffic! Proposals were nevertheless placed before the Treasury to provide a telegraphic cable and land lines to France of such a character as to be suitable for telephonic working if the establishment of an Anglo-French service were decided on. Treasury sanction to the scheme was given in January, 1890, and the necessary credit having been voted by France in the August of the same year, tenders for the cable were sought. Messrs. Siemens obtained the contract, and manufactured the cable at Woolwich; it was a four-core cable 20.965 knots, in length, weighing 160 lbs. copper and 300 lbs. gutta percha per nautical mile. The laying of the cable between St. Margaret's and Sangatte was carried on in a blizzard in the following year, and completed with great risk and difficulty on March 14, the service being opened to the public on April 1. The cable contained 2 London-Paris telephone circuits and was completed (together with the land lines) at a cost of £23,704, of which France paid £6,356 as their half-share of the cost of the cable.

The following graphic account of the laying of the cable by the *Monarch* is taken from *The Times* of March 18, 1891 :—

The telephone cable was stored in the main tank. The steam capstan had been removed and a horizontal spiderwheel or sheave mounted on its axle. The end of the cable, which was coated with whitewash to keep the coils from sticking together, was brought from the tank in Siemens' factory and carried over the intervening water by two pulleys elevated on barges anchored in the Thames. It went round the spider wheel, took three turns about the picking-up drum on the port side, then passed to the main tank, where a dozen hands in white overalls took hold of it and, with the help of iron levers, coiled it neatly, flake upon flake, at the rate of 1¼ to 1½ knots an hour. It is a good cable—"one of the best ever made" was the verdict of Mr. Lumsden (the Engineer-in-chief of the *Monarch*.) Thicker than an ordinary ocean cable, with a single core, the line was beautifully pliant and fell into its coils with the easy motion of a snake.

On Tuesday evening, March 3, the *Monarch* left her moorings near the *Warspite* and put to sea. Next morning she arrived off St. Margaret's Bay, a pretty cove in the chalky cliffs of the South Foreland, with a gravelly beach well fitted for landing a cable. A favourable wind, a smooth sea, and, above all, a clear day, so that the opposite coast can be described as a mark for the ship, were the requirements in the way of weather for the laying of the cable. Mr. Lumsden had sufficient cable to cross, but not much to waste by wandering from his course. For several days there was a nasty swell on the sea and a disagreeable haze. It was impossible to communicate with the shore, and the *Monarch* lies rocking idly at her anchor. She had a distinguished visitor in M. Amyot, the Inspector-General of the French telegraph administration, accompanied by his assistants, MM. Messin and Thomas, who were present on behalf of the French Government during the laying, and who afterwards proceeded to London to make experiments on the line, while officials of the Post Office were present in Paris. Mr. W. R. Culley, assistant-superintendent of the submarine department of the Post Office, was also on board to see the laying and mark the position of the cable.

After waiting nearly a week in hopes of better weather, the morning of Monday, March 9, broke fine and clear. There was a stiff north-easterly breeze at Sangatte, registered as 4 deg. on the nautical scale, and nothing more. The glass was steady, the sea smooth, all the way across, and the white cliffs at St. Margaret's were plainly visible to the naked eye. The long-expected opportunity seemed to have come, and preparations were made for landing the shore end of the cable into the hut at Sangatte. The two lifeboats were lowered, and a strong platform placed across them to form a raft, on which a length of cable sufficient to reach the shore was quickly coiled by the cable hands. The steam launch took the boat raft with the black coil of the cable in tow, the men paying it by hand as she went along to ground. She cast off and gave place to the men, who, in their white overalls and sea-boots, dragged the cable up the sand, along the trench, and into the cable hut. It was half-past 9 when the lifeboats were launched and 12 minutes to 11 when the end was landed. No time was lost in returning to the ship, which immediately started paying out towards St. Margaret's Bay. The cable ran smoothly out of the tank, through the iron "crinoline," which keeps it from lashing about with the rolling of the ship, it glided along the guides, took three turns round the huge revolving iron drum, with its friction-brake which controls the speed of egress, and passed over the starboard sheave or pulley projecting from the bows, then dived into the sea, just grazing the hull about the water line. Mile after mile was traversed in this way, and all was going on well. As yet there were no signs of an approaching storm. A drizzling rain began to fall, and the breeze freshened, but it was not until towards 3 o'clock, when 10 miles of cable had been paid out, and the *Monarch* was half seas over, that the gale came on, and the water became rough. The glass fell rapidly, and soon a blinding snowstorm swept over the vessel. It was still possible to see for a considerable distance all round, and there was no danger of a collision, but the weather grew worse every moment. Mr. Lumsden had no intention of cutting the cable and buoying it. The captain knew how far he had gone on the course the *Monarch* was pursuing, and that he would soon fetch up off St. Margaret's Bay. The sea was lashed into fury by the violence of the gale which increased to 9 deg., but the decks of the *Monarch* rode high, and there was little or no spray. The whirling flakes of snow were the enemy, and they drove on thicker and thicker, keener and keener, till the cheeks tingled and smarted as if they were being cut with crystals of ice. The lookout could only see a short distance ahead, and although the *Monarch* was nearing the land the white cliffs were invisible. At length it was decided to anchor until a lull in the storm should reveal the land, if only for a little while. The cable was fastened and the anchor rattled out soon after 4 o'clock. The whistle was sounded to give notice of her whereabouts, but the signal was unheard above the storm. A gun far out at sea, announcing a ship in distress, was heard and mistaken by the folk on shore for a signal from the *Monarch*, but she never fired a gun. The snow cleared about 5 o'clock, and it was then discovered that she was lying off St. Margaret's Bay, about a mile from the shore, and eastward of the cable hut.

Captain Thompson had made a good hit in spite of the blizzard. Having found his bearings, an attempt was made to lift the anchor and pay out all the cable, but the strong tide, aided by the furious wind, had driven the cable foul of the anchor, and after a fruitless attempt to clear, the anchor was slipped with 14 fathoms of chain. It was now a quarter past 8 at night, and very dark, but the *Monarch* paid out the rest of the cable to avoid cutting it, and buoyed the end well off the shore to the east of St. Margaret's Bay, about 20 minutes past 9, then ran for the Downs, where she anchored soon after 10 o'clock. Next morning the dirty white cliffs of the headlands and the bleak hollows of the Downs were patched with drifted snow, and the scene was wintry in the extreme. A tawny sea, lashed into foam by a strong easterly gale, with squals of mist and rain, prevented further operations. Wednesday was not much better, for, although it brightened up, the glass was still unsettled. The *Monarch* was now lying at Dover, where she went to land a visitor and take in stores. Thursday was fine, and after picking up the cable from the buoy she proceeded to clear it from the lost anchor. The line was coiled four times round the anchor, and could only be released by cutting out the damaged part. This was done, the anchor and chain being recovered, and the end of the cable buoyed. She returned to Dover. On Friday nothing could be done owing to the high wind and sea; but Saturday morning was as quiet as a lamb, the blue sky smiling through fleecy clouds. The *Monarch*

Digitized by Google

was early astir, and although the sea was a little hazy, and a strong easterly breeze blowing, the glass was very steady. The ship had spliced the cable by 20 minutes past 11, and then picked up some five miles of cable from the buoy, towards Sangatte, relaying it so as to clear a bight in the Calais-Dover line, arriving off St. Margaret's Bay about 20 minutes past 3 in the afternoon, where she anchored 1,000 yards away from the landing-place. A raft was speedily formed with the lifeboats, and the shore end landed in the same way as at Sangatte. It was now getting dusk, but groups of spectators had collected on the beach to watch the operations, and a local photographer, deputed by a London illustrated paper, took a picture of the scene. The end was hauled ashore by the sailors at 10 minutes past 6, and 12 minutes later brought into the cable hut. Lieutenant O'Meara called up St. Martin's-le-Grand and announced the good news. Three cheers were given at the Post Office and in the hut through the land line, and those from London sounded so lustily that the lieutenant declared they had split the drum of his telephone. The end of the cable was then stripped and the sheathing filed off, the rasping of the file being plainly heard in London. The cores were then pared, and the cable connected to a Morse apparatus, by which the hut was put in communication with Sangatte. The French electricians there telegraphed a "hurrah for the telephone," and the work was done.

An agreement providing for the establishment of the service was signed on May 17 and June 16, 1891, after approval by the Foreign Office.

The charge for 3 minutes' conversation was fixed at 10 francs. The two Administrations had some difficulty in arriving at a basis for this charge. No estimate could be formed of the revenue likely to be derived from the telephone service, the conditions being altogether novel and the requirements of the public a matter of pure guess work. The traffic on the Paris-Brussels trunk line afforded no guide; there was no difference of language to contend with in this case, and the line was in constant use. This question of difference of language was for some reason regarded as a considerable stumbling block in those days; it was apprehended that the use of the London-Paris service would be confined to comparatively few people, and it was thought necessary to charge a substantial sum. The French Administration, the British Chamber of Commerce in Paris and Mr. Lamb were all in favour of a charge of 10 francs, and 10 francs was adopted—as a tentative measure, to which the Postmaster-General (Mr. Raikes) agreed with reluctance, and on the understanding that the charge should be reduced when the traffic increased.

Not only did the Post Office at that time expect the use of service to be confined chiefly to stockbrokers and financial houses, but access to the service was denied to the National Company's subscribers, as this course could not be recommended whilst their London service was worked on the single wire system. The service was, therefore, limited to call office traffic and to such subscribers as were subsequently connected directly with the trunk switch.

Call offices in connexion with the Paris circuit were opened at the Central Telegraph Office at Threadneedle Street, and at West Strand. A switch was provided at the Central Telegraph Office to which any wires rented by subscribers might be led, and the Anglo-French traffic was dealt with there until the Anglo-Continental telephone circuits were transferred to the London Trunk Exchange in February, 1904. The use of the service by National subscribers was first permitted under the Purchase agreement in 1905.

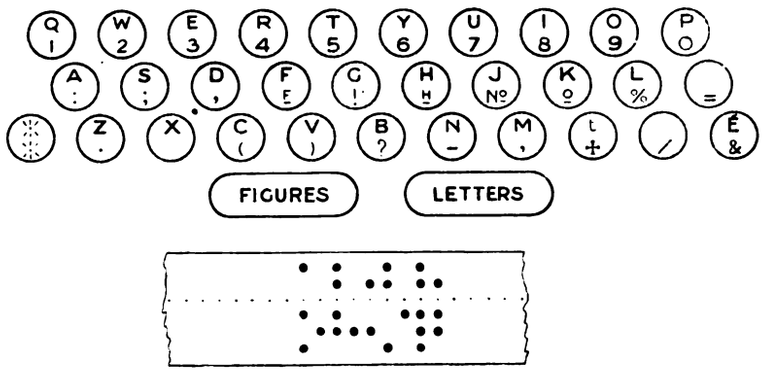
According to contemporary press reports the opening ceremony on March 17 was highly successful. Greetings were interchanged between Mr. Raikes, the Postmaster-General and M. Jules Roches, the French Minister of Commerce, and after Mr. Raikes had transmitted a message from the Prince of Wales to M. Carnot, the President, the British Press conversed with their confrères in Paris. The official speeches were subsequently telegraphed in full, although the speaking is reported to have been very distinct, *The Times* remarking that the peculiarities of accent were easily distinguishable. The *Daily Telegraph* said, *more suo*; "electricity annihilates distance, so far as this pigmy earth is concerned, for there is no appreciable interval between the wave vibrations produced on the transmitters in St. Martins le Grand and their reproduction on the receivers in the Rue Grenelle. The imagination of poets and romancists never achieved any wilder flight of fancy."

The traffic on the first day amounted to 22 calls, with all of which the speakers expressed their entire satisfaction. By the following year (1892) the traffic had risen to 3,018 calls a month, and it steadily increased until it had reached an average of 4,764 a month in 1895. The delay in the busy hours amounted at this time to an hour or an hour-and-a-half, and it became necessary to provide additional circuits. Each Administration agreed to become responsible for the provision of an additional cable, and in 1897 two new cables were laid, one between St. Margaret's Bay and Sangatte by the British Post Office, and another between Abbot's Cliff and Gris-Nez by the French Administration. After prolonged correspondence between the two countries, in which the claims of the telegraphic and telephonic service were carefully weighed and contested, it was agreed to allot 6 wires to telephones (forming 2 London-Paris and 1 London-Lille circuit) and 2 to telegraphs.

CARTOON FROM *Punch* INSPIRED BY THE OPENING OF THE ANGLO-FRENCH TELEPHONE.

On the completion of these 3 circuits, the French Government submitted a draft agreement suggesting the division of the country into zones for charging purposes, and the introduction of reduced charges at night. These proposals were finally embodied in an agreement, which was signed on July 29, 1902, and by 1904 service was in operation not only between London and Paris, but between Birmingham, Cardiff, Bristol and the Lancashire and Yorkshire towns on the one side and Amiens, Armentieres, Bethune, Bordeaux, Boulogne, Caen, Calais, Cambrai, Chartres, Denain, Dieppe, Dijon, Douai, Dunkirk, Elbeuf, Havre, Lens, Lille, Lyon, Marseilles, Nancy, Orleans, Roubaix, Rouen, St. Etienne, St. Quentin, Tourcoing, Tours, and Valenciennes on the other.

(*To be continued.*)



The Royal Insurance Co., of 1, North John Street, Liverpool, have forwarded to us a very handy pocket book of the rules of the Royal and Ancient Golf Club of St. Andrews. They offer to supply readers with a copy, so far as their stock will permit, on application to Liverpool, or to Lombard Street, London.

BOOTH-WILLMOT TELEGRAPH KEYBOARD PERFORATOR.

THIS perforator is of the typewriter pattern, having the keys arranged in the standard order, and with two characters to each key. The letters or primary characters are arranged to actuate the punches in accordance with any particular code, while the secondary characters, including the figures, may be arranged in any desired order. With the standard arrangement the figures are placed in numerical order as secondaries to the back row of keys, and this plan is followed in the Booth-Willmot arrangement, although the signals for the figures may be partly or totally different from the signals representing the letters on the same keys. For instance, with the original Baudot code the secondary of letter "Q" is the oblique stroke, while figure "1" is secondary to letter "A," but with the Booth-Willmot device figure "1" of the Baudot code is secondary to letter "Q" of the Baudot code, similarly with the other figures and symbols. Hence a standard arrangement of the keys can be used for a Baudot keyboard perforator. A plan of the keys with their symbols is given in Fig. 1. As Baudot operators will note the specimen of slip punched represents the word "telegraph" as it would be signalled from an ordinary keyboard, and is thus very easily read by any Baudot telegraphist.

The device also permits of an exactly similar arrangement being used for the Morse or Wheatstone keyboard perforators, the key for the Morse letter "Q" producing Morse figure "1" as secondary. It also provides space for additional Morse characters and avoids the use of 3 keys for several Morse symbols, which is a necessity on the Gell and Kleinschmidt perforators.

It will permit of the use of a similar arrangement of the keys, so far as the operator is concerned, on all the various arrangements of the 5-unit alphabet, of which the chief are as follows:—

(1) Original Baudot code ... ... "5-unit A."
(2) Murray duplex multiplex ... ... "5-unit B."
(3) Western Electric duplex multiplex ... "5-unit B."
(4) Morkrum system ... ... "5-unit B."
(5) Siemens' automatic ... ... "5-unit C."

The 5-unit A, B and C codes differ radically both in their primaries as well as in their secondaries, but perhaps in the course of time the different administrations will decide to bring all these codes into line, at least so far as the letters, figures and control signals are concerned, leaving a few secondaries to be allocated for special characters peculiar to each administration.

The Booth-Willmot device, besides providing a perforated slip, at once readable by all Baudot operators, permits of the use of the usual 5-key Baudot keyboard as an alternative on the same channel for speaking purposes, without disturbing the perforated slip in the automatic transmitter, or requiring any alteration in the Baudot receiver.

It is believed that the Postmaster-General has granted permission for patent rights to be obtained.

An experimental keyboard has only recently been placed on one of the Anglo-Continental circuits, so that it would be premature to make further comment except that the prospect of its success is promising.

It is understood that the official designation of this form of keyboard is to be known as Post Office 1921 design for foreign Baudot circuits.

signals is maintained in phase with its own particular sector of the distributor to which it is allocated. The running speed of such receiver is fixed at a figure slightly higher than that of the distributor which from Rings 3 and 6 automatically transmits a checking or braking current from a local battery of 40 volts by means of the rotating brushes. The latter, as already mentioned, from the same pair of rings and by means of certain other of the segments

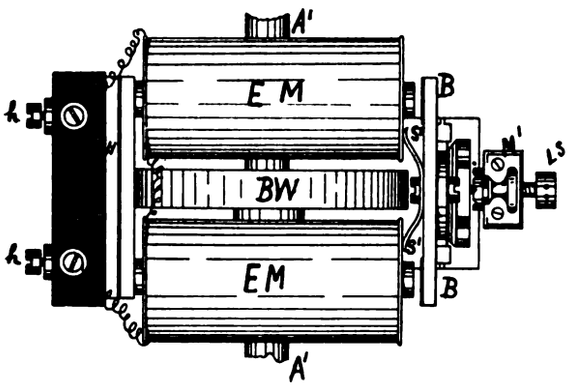

FIG. LX.

of Ring 3 serves the keyboard of each arm with its *cadence* for transmitting purposes. The brake current passing from Ring 3 is led to terminal 6 of the receiver connexions (Figs. LVII and LVIII) thence passing through the electro-magnet brake coils EM (see also Figs. LX and LXI), to terminal 7 (Figs. LVII, LVIII), thence to the lower of two long steel contact springs SC^1 at *l* (Figs. LVIII and LIX). The contact springs SC and SC^1 are fixed to an ebonite strip F, which insulates them from the back

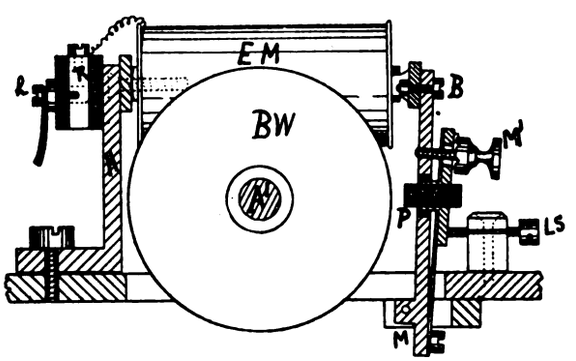

FIG. LXI.

casing of the receiver, to the inside of which the strip F and the balance lever L are fitted. K^4 is a cam fitted on the type-wheel axle X just below the nose *d* of the balance lever L. This lever oscillates on an axle pin a^1 and when by the rotation of the axle X the eccentric portion of K^4 reaches *d* the lever L is lifted against the gentle pressure of SC and depresses the opposite end *e* bringing SC into electrical contact with SC^1 and thus extending the path of the current which completes its circuit through the axle-pin a^1 and the receiver casing to earth. The contact springs SC and SC^1 carry platinum contact tips A. B. An insulated limitign stud *i* keeps SC^1 in position when the latter is at rest.

Upon the base-plate of the receiver is fixed a horizontal pair of electro-magnet brake coils EM (Fig. LVIII) and of which more details are given in Figs. LX, LXI. An axle A^1 with bearings at the front and rear edges of the base plate (Figs. LVIII, LX, LXI) is extended rearwards and thereon carries a speed governor known as the *moderator* upon it. On the centre of this axle also rotates a brass fly-wheel or brake wheel BW (Figs. LVIII, LX, LXI) the electro-magnet coils EM being fixed, one each side of BW being held in position by screws fixing the coils end-on to an upright metal support H and an ebonite block R.

(To be continued).

REVIEWS.

"*Management: A Study of Industrial Organisation.*" *By John Lee, M.A.* 125 *pp.* 5*s. net. Sir Isaac Pitman & Sons.*—This book, as the preface records, took its origin in lectures to audiences of men and women interested in problems of organisation, amongst them the members of the London Telephone and Telegraph Society. Some of its chapters will therefore be familiar to our readers, although they have been thoroughly revised, especially that on the subject of the Psychology of Supervision which aroused such keen interest when it appeared in our columns. Our readers know what to expect from Mr. Lee's pen, and will not be disappointed with his treatment of the subject of the volume under review. Mr. Lee reviews with breadth of outlook and sympathy the progress of industrial control from the early stages of absolute ownership to the later forms of Whitleyism and divided control, dealing on the way with such questions as functional management, directive management, scientific management, promotion and discipline, theories of wages, welfare methods and Whitley councils. In conclusion, he says :—"We need some correlation of experience, some interchange of thought between those who have struggled through in the way which I have described and have achieved something in the way of result. In time to come I hope the Universities will supply such correlation. It will not reach the height of dogma. We shall always be ready to learn from new experiences of others, especially from the experiences of those in other countries where industrial conditions are different. . . . Management to be worthy of the name will be unsatisfied until it is so sensitive that the hard articulation of the thread of conflict will not be needed."

"*The Practical Electricians' Pocket Book and Diary,* 1921." *S. Rentell & Co., Ltd.* 522 *and* lxxv pp. 3*s. net.*—It is difficult to find anything new to say about this well known and useful little annual, now in its twenty-third year. It has been revised and is as usual thoroughly up-to-date. We note that it has been recommended by the City and Guilds' Examiners for Electrical Installation work.

"*Arithmetic of Telegraphy and Telephony.*" *By Herbert and De Wardt. Pitman & Sons.* 5*s. net.*—A very useful book by Messrs. Herbert and De Wardt of the Post Office Engineering Department, the former of whom is the writer of the well-known book on Telegraphy. The student in technical subjects often times finds himself at a disadvantage when only at the threshold of his labours through his knowledge of arithmetic having lapsed to some degree by disuse. This work is well designed as a refresher to such persons, and as an aid to entrants for the course of Telegraphy and Telephony.

The opening chapters are devoted to a description of the simpler rules of arithmetic, followed by examples and exercises at each stage, the answers to the 250 problems being placed at the end of the book. The volume consists of upwards of 150 pages of clearly printed matter, the fifteen chapters include such necessary branches in the Elementary Course of Telegraphy and Telephony as Ohm's Law, Measurement of Cells, Conductors, Current, Resistance and Condensers, with skeleton diagrams for illustrative purposes in some instances. Messrs. Herbert and De Wardt may well be congratulated on their work, which should be in the possession of all Elementary Telegraphy and Telephony Students.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. JUNE, 1921. No. 75

"THE FOUNDATIONS OF BELIEF."

"IT is not easy to trust implicity," says a paragraph which has appeared in several well-known provincial newspapers, "the calculation of the Post Office authorities that out of 9,000 subscribers to the telephone service who have given notice to terminate their agreements which ended last March only 3,000 have done so as the result of the increased charges." It is, in fact, preferable to trust vague statements, dark prophecies, vain assumptions, fixed impressions, colorable conjectures, flying rumours, and specious fables than a computation carefully arrived at from actual documents. We are glad of the implied admission; but it is really superfluous. It is much more dramatic, much better copy, to say that "nearly all" the subscribers in X are giving up their telephones because of those abominable and extortionate new rates than to record the unexciting fact that only two per cent. have done so. It is said that we believe most readily what we wish to believe. It is certainly not in human nature to accept without protest facts or statistics which go to prove that a deep-seated impression is all wrong. Perhaps this is why statistics are commonly in such bad odour, and why the statistician's profession is accounted venal, for figures, it is often said, can be made to prove anything.

It must be remembered that the columns of the Press have contained numerous statements during the past month or two to the effect that large numbers of subscribers in this or that town have refused to sign agreements for service at the new rates. In some cases the number is put at half, in others at "nearly all," Numerous letters also have appeared from subscribers vehemently announcing their intention of discontinuing. Quite naturally one would assume that these withdrawals would affect the returns of the whole country in some striking manner. We can understand the astonishment and disappointment of the journalist looking for dramatic developments, and his pardonable doubt on being told that while 3,000 subscribers had terminated their agreements on account of the increased charges, 6,000 had done so for ordinary causes.

It is not perhaps understood by the Press and the public that in normal times some two to three thousand out of the great body of subscribers to the Post Office telephone system give up the telephone every month, owing to death, retirement, failure, or other valid reasons. Since the inception of the new rates 16,500 new agreements have been signed, and the number of telephones in use in this country is now nearly a million.

HIC ET UBIQUE.

THE *Wall Street Journal* of New York recently published a criticism on "British Government Ownership," chiefly in reference to the new rates. We are fairly well hardened to unscrupulous attacks, but the article in question surpasses the usual limits of controversial mendacity. "There is a system of recording calls," we are told, "and charging for them, which would not be tolerated here for a week. The renter of the telephone calls a number and is electrically recorded thereupon (*sic*) as making a call. After ten patient minutes, he calls 'Central' again, having failed to get his number. For this 'service' a second call is charged to his account."

So far from not being tolerated for a week, the British method of charging for calls is precisely that in force in New York; that is to say, the call is not recorded by the telephonist until the two subscribers have been placed in communication. This method was investigated and approved both by the London Chamber of Commerce and by the Merchants' Association of New York.

THERE is, we learn from *Telephony*, a strike of 700 telephone subscribers in Bloomfield, Nebraska. Although the State Railway Commission duly authorised an increase of about 22 per cent. on the old rates, the subscribers have voluntarily cut themselves off from the service. A committee of bankers and business men requested the Commission to order a reduction of rates, but the Commission will not allow the Company to reduce its rates, even if it should seek that way out of the difficulty, because the law having being invoked must govern. "Meanwhile," we are told, "the strikers are reported to be looking for some way to let go of the bear and at the same time save their faces."

"NOTHING," says the *New York Times*, "can make increased cost of necessaries popular, but Americans will accommodate themselves to whatever they believed to be just, even if they register a protest, which is both lawful and economic, by going without whatever they dislike the price of. The Public Service Commission, having heretofore reduced telephone rates and increased wages by eleven million dollars, finds that the telephone company is unable to earn its operating expenses. Accordingly the Commission allows the company to increase charges enough to yield eleven million dollars more annually." *Telephony*, in quoting the foregoing, commends the sane attitude of *The Times*. "Politicians and yellow newspapers," it says, "oppose adequate rates for utilities and seek to befog the issue so that the public will flock to their banner heedless of the inevitable fact that resulting losses must eventually be made up in increased taxes." No comment from this side of the Atlantic seems necessary.

A CORRESPONDENT of the *Weekly Despatch* basking, if we may so put it, in Northern lights, and describing how their magnetic effects disorganised temporarily several telegraph and telephone lines in Sweden, explains that a milliampere is a measure of electrical brilliance. Journalistic brilliance admits no obstacles, and would seem to have as devastating an effect on things electrical as the brilliance of the Aurora.

THE *Near East* gives information of a projected General Telephone Company of Persia. A circular asking for subscriptions issued in Teheran in English exhorts the reader not to miss this chance to benefit himself and the public, but to "take part in this great fortune which is indeed the key to prosperity of the individual as well as of the public and the country." Apparently we must go to the East to hear such nice things about the telephone. In no other way, we are told, is it possible for two friends or commercial correspondents, who are separated, whether near or far, to inform each other of their family matters or trade secrets.

TELEPHONE AND TELEGRAPH MONOPOLY.

"*La Legislation Télégraphique d'après les documents officiels.*" (*Bureau Internationale de l'Union Télégraphique, Berne*, 1921, 1,064 *pp.*)

This useful compilation, which contains a digest, and in many cases the text, of the telegraphic and telephonic laws of forty countries, we do not propose to review in the ordinary way, but rather we shall attempt to extract from it some facts and data for the instruction, and, if possible, edification of our readers. It covers the whole field of telegraphic legislation, dealing with monopolies, sub-licences, royalties, wayleave rights, protection of lines, etc., and would prove an invaluable basis for a comparative treatise of the practice of state telegraph administrations. Over 160 pages are occupied by the enactments of the United Kingdom, ranging from the Telegraph Act of 1853 to the Acts of 1899, 1904 and 1907.

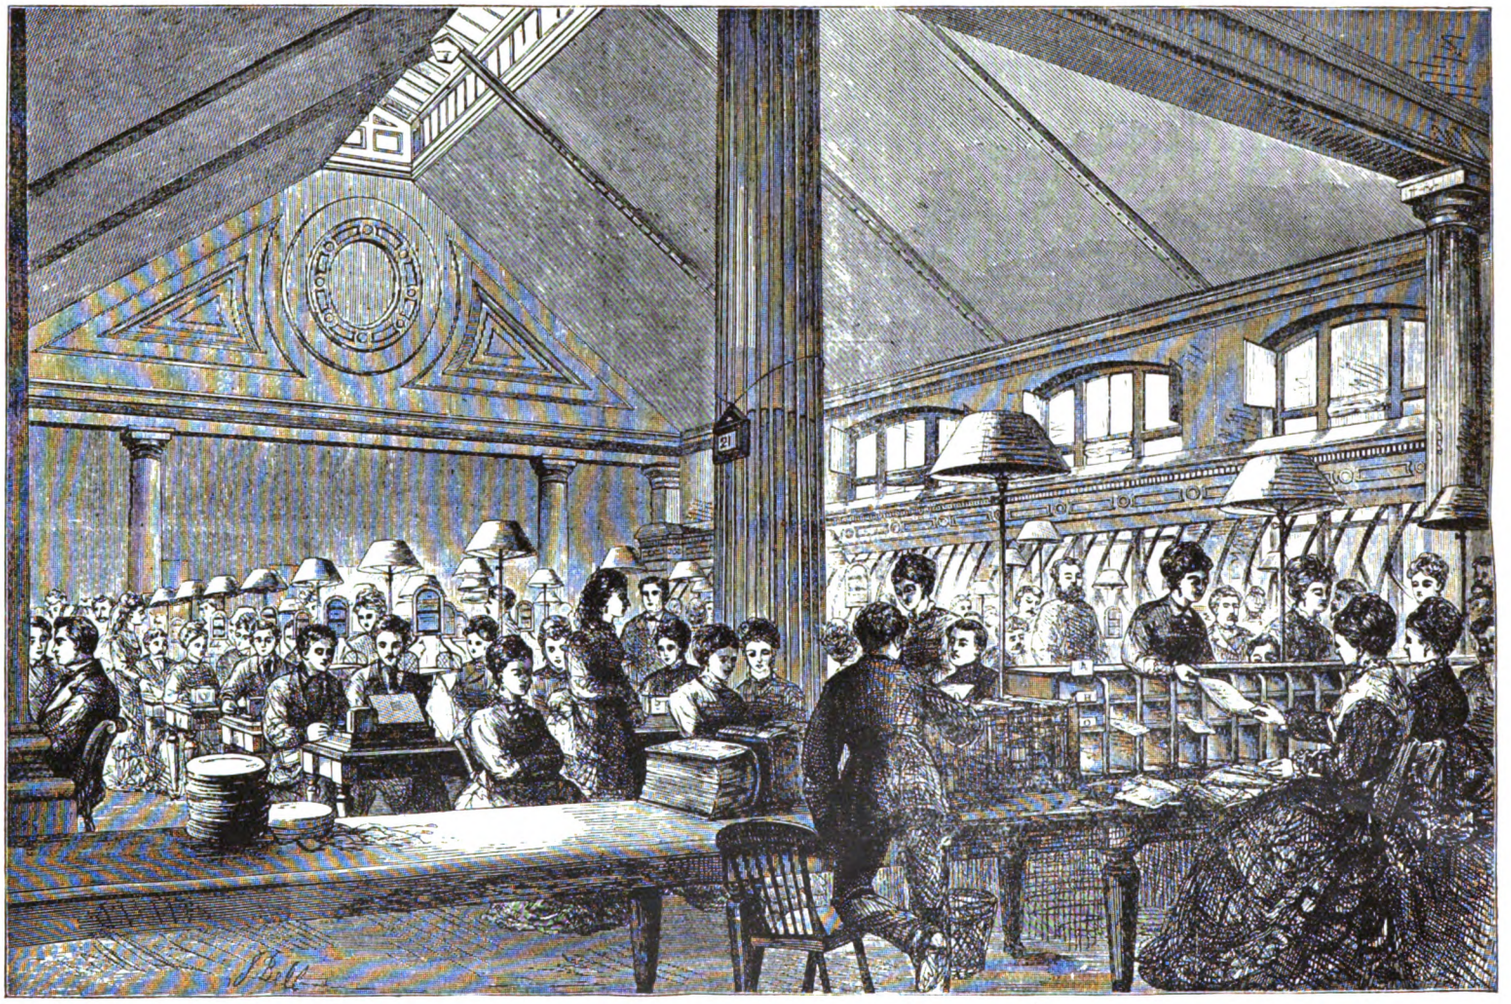
"The study of British legislation in telegraphic matters," says the compiler, "is of particular interest by reason of the special conditions to which the telegraphs of the United Kingdom have been successively submitted in their origin, in their development, and in their transfer. In Continental countries this new mode of communication having been instituted by the State from the beginning, legislation was obliged to regulate the principal conditions of its establishment and working in a more or less complete manner. In England, on the contrary, where the establishment of the telephone was long left to private industry, the legislative authority did not have to intervene until the service had attained to a considerable development when in the general interest the State judged it useful to assign it to the Post Office." Then, accompanied by explanatory paragraphs, follow excerpts from the various acts bearing on the purchase of the telegraphs, the establishment of the monopoly, the protection of lines, and the purchase of the telephones.

The compiler records the Attorney General's judgment of 1880 that "the telephone is a telegraph in the sense of the laws of 1863 and 1869." It is interesting to note that this opinion was not confined to British lawgivers. Immediately after the invention of the telephone, the German Government announced their opinion, maintained ever since, that this means of communication was a subgenus of telegraphy and within the competence of the Empire. This was confirmed by the law of 1892 in which it was expressly stated that the expressions "telegraphic establishments" comprised also telephones. In France it was held that the laws which conferred a telegraphic monopoly on the State referred not only to electric telegraphy, but to all distant transmission by signals by any means whatsoever. Concessions were granted to companies in 1879 to establish telephone systems in Paris, Lyons, Bordeaux, and Marseilles, but a law was passed in 1889 authorising the purchase of these systems, since which date the telephone has been a state monopoly. The Belgian Government also claimed that the telephone service came under the telegraph law of 1876. On the invention of the telephone they authorised the construction of telephone lines at the demanders' risk and peril under payment of a tax, and in 1883 their monopoly was fixed by law. Certain exchanges were constructed by licensees and repurchased 1893-96, and others were exploited by the State itself. In Austria, also, where telegraphic monopoly was conferred by a law of 1847 the telephone service was first established by licensees and acquired by the State 1893-95. In Switzerland the law of 1889 decreed that the exploitation of telephones formed part of the telegraphic service (monopoly conferred in 1851). In Russia the law of 1881 lays down that telephonic communication forms part of the telegraphic monopoly (conferred by the law of 1855). In Sweden there is neither a telegraphic nor a telephonic monopoly, but a law of 1906 provides that no company or person may establish telegraphic or telephonic communication on crown lands, public roads or railways without royal sanction. The telegraph and telephone service is, however, chiefly in the hands of the State. As regards Denmark, an Act of 1897 permits the Minister of the Interior to grant telephonic and telegraphic concessions of a maximum duration of 20 years.

State telegraphic monopolies are of long-standing in Europe. That of Austria dates from 1847, Belgium from 1850, France from 1851, Switzerland 1851, Sardinia 1853, Russia 1855, and Great Britain 1869. Telegraphic communication was regulated by the State in Holland as early as 1852 and in Prussia and the North German States before 1851. By the year 1853, therefore, the lines of all the States of continental Europe which possessed a telegraphic system of any importance (*i.e.*, France, Belgium, Holland, North and South Germany, Austria, Northern Italy and Switzerland) were under State control.

As we have shown, this monopoly was generally held to include the telephone, when that means of communication was introduced to the public. In some countries the telephonic monopoly was specifically confirmed by subsequent legislation, in others not.

We detect one small error in the book. Municipal boroughs are defined in a footnote as boroughs having the right to return members to Parliament. Many municipal boroughs do not, and never did, even before the days of the Reform Bill, return members to Parliament; some parliamentary boroughs are not "incorporated," and the boundaries of several towns which are both corporate and parliamentary boroughs are not coterminous.



W. H. G.

POST OFFICE WORKMAN CAPTURES HOUSEBREAKERS.

Prompt action on the part of a gang foreman recently led to the capture of two housebreakers in a South-West suburb. The foreman, hearing cries for help emanating from an adjacent garden, hastened to the spot to find an old gentleman bleeding from an injury to the head and to learn that the injury had been caused by a brutal attack from two housebreakers who were still at their nefarious work in the premises. The foreman notified the police from a nearby telephone, and commandeering the assistance of a passer-by, returned to the house just in time to grapple with one of the housebreakers who was escaping by the back entrance. They trussed him up with a clothes rope conveniently at hand, and, with zeal whetted by this preliminary success, waited for the second housebreaker, who now had jumped from an upstairs window on to the kitchen roof. On seeing the plight of his "pal," however, this second man retreated to the house, but observing at this moment the arrival of fresh reinforcements in the shape of the police he was wise enough to surrender.

The irony of the whole thing, so far as the foreman is concerned, lies in the newspaper report of the subsequent Police Court proceedings. In this report the constable effecting the arrest is stated to have said "I arrived at the house in time to capture Jones as he ran out of the door. He struggled and I tied him up with rope. I then saw Williams rush out of the door and *with assistance* arrested him." Unfortunately, the gentleman who knew the real facts was unable to appear owing to the extent of his injuries.

(*From the "Illustrated London News," Dec.* 12, 1874.)

THE CENTRAL TELEGRAPH OFFICE: INSTRUMENT GALLERY.

THE CENTRAL TELEGRAPH OFFICE IN 1874.

WE reprint some interesting pictures of the Central Telegraph Office as it was in 1874, which appeared in the *Illustrated London News* of Nov. 28 of that year. The following excerpts from the accompanying text throws some light on the number of staff and volume of traffic in those days:—

The Central Electric Telegraph Establishment at the General Post Office is one of the most admirable results of administrative organisations for business, and of science applied by an apparatus of exquisite precision to the needs of social life. We have great pleasure in setting before our readers a few illustrations of the machinery and the methods here employed for the most rapid transmission of intelligence between all parts of the United Kingdom, and for its communication, also, to the submarine and foreign lines. Before attempting to explain the subjects which our artist has drawn, we would thank the official gentlemen of this department—especially Mr. H. C. Fischer, the controller—for the opportunity lately granted us of making a personal examination. It would be superfluous to comment or to congratulate any of them upon the beautiful order and wonderful efficiency with which everything there is arranged and conducted.

The large and handsome new building in St. Martin's-le-grand, at the corner of Newgate Street, facing the old building of the General Post Office, was shown in an illustration we gave some time ago. Its upper portion is occupied by the collective staff and instruments of the Central Telegraph Station, removed in January last, but with great additions, from their old quarters in a lane off Moorgate Street, near the Bank of England. There are 1,240 instrument clerks, of whom 740 are females, and there are about 270 messengers This does not include the engineering staff, or that of the Controller. Between five and six hundred instruments are here kept at work, and the wires therewith connected within and beneath the building have an aggregate length of nearly three hundred miles. Besides this electric apparatus there are twenty-six lines of pneumatic tube, with air-pumps worked by three powerful steam-engines, for conveying messages bodily, by means of atmospheric power, between the principal City offices and the West Strand office, opposite Charing Cross Station, and the Central Telegraph Office. . . .

To this gallery, on the third floor, we now ascend by the wide staircase, enjoying by the way, the ample provision for clear light and fresh air, and the cheerful aspect of the whole interior. The instruments, of various kinds and uses, occupy a great central hall with four wings, one at each corner. These it will be convenient to mention as the north-east and south-east, the north-west and south-west galleries. The north-west gallery is for messages to and from Scotland, the north of England, and Ireland. The south-west is partly devoted to newspaper despatches and reports, and to the special "racing circuits;" the extra force of spare instruments, on Wheatstone's automatic system, is placed here, for use on particular occasions. The two eastern galleries are mainly occupied by the metropolitan telegraphs. They contain 263 instruments, of which 21 are duplex, 101 Morse printers, and 100 single needles. The central hall contains the instruments which are connecte with the different provincial circuits of England. The provincial telegraph business employs 205 instruments at the Central Office; and of these 57 are Wheatstone's aut matic, 20 are duplex, 7 are Hughes's type-printers, and 97 are Morse printers. But on the south side of the central hall are the pneumatic despatch-tubes for sending telegrams bodily, through an underground tube, to or from the more important London offices. On the west side is a tall and wide frame called the test box, exhibiting in its front a great number of metal knobs and wires; these afford means of establishing an electric communication with any station throughout the kingdom. They derive their power from 4,000 cells in the Battery Room. The battery test box, above referred to, and the sympathetic clock, with the chronifer or regulator of clocks, are situated also here, between the two western galleries. The total floor space is 20,000 square feet; the mahogany desk space extends in length three-quarters of a mile. Mr. H. Eaton, as superintending engineer, is in charge of all the instruments on this floor. We are indebted to one of his staff, Mr. T. Hill, for much assistance in preparing this account.

It is a cheerful scene of orderly industry, and it is, of course, not the less pleasing because the majority of the persons sitting here are young women, looking brisk and happy, not to say pretty, and certainly quite at home. Each has her own instrument on the desk before her. She is either just now

SKETCHES AT THE CENTRAL TELEGRAPH ESTABLISHMENT, GENERAL POST OFFICE.

Digitized by Google

actually busied in working off or in reading some message, or else, for the moment, she awaits the signal, from a distant station,to announce a message for her reception. Boys move here and there about the galleries, with the forms of telegrams which have been received in one part of the instrument room, and which have to be signalled from another, but which have first to be conveyed, for record, to the nearest of the check tables and sorting-tables in the centre. Short pneumatic tubes facilitate the distribution and collection of papers in this building. The total number of messages daily received or sent at this Central Office is from 26,000 to 30,000. But of these a very large part, 17,000 or 18,000, are transmitted through the central office from other offices, and have to be repeated and forwarded; so that, in each case, there is the work both of receiving and despatching, though each is counted but as a single message. In addition to the number above stated, newspaper telegrams and reports, often lengthy, are sent through this office, more especially during the night. The female instrument-clerks do not remain for the night work, and their labour does not exceed eight hours a day, with half-an-hour allowed for dinner, which is comfortably provided for them in their own dining-hall. Five or six thousand of the day's messages are transmitted to or from the Anglo-American, the Eastern, the Northern, the Indo-European, the Submarine, and other foreign lines. Three thousand a day, on the average, are messages within the London district. The markets, the Stock Exchange, the races that may be going on, and other business of the day, communicated at once to all the chief towns in the United Kingdom, give some hours' employment to many instruments in the morning and afternoon, besides all sorts of private messages. In the night work of newspaper reporting, which begins at eight o'clock in the evening and continues two or three hours after midnight for the morning papers, 200.000 or 300,000 words are not unfrequently telegraphed to the provincial press. The heaviest task of newspaper-reporting telegraphy yet done was on a Budget night in Parliament, to the amount of 427,000 words.

SELECT COMMITTEE ON TELEPHONE SERVICE, 1921.

RESUMÉ OF EVIDENCE.

April 6.—Sir EVELYN MURRAY, the Secretary of the Post Office, was the first witness called. After giving a short historical survey of the Telephone Service, he explained how the engineering programme had been delayed by the war and the delay in completing exchanges and connecting subscribers. He quoted figures showing that the London service was practically restored to its pre-war efficiency. He explained the method of registering calls in force, which had satisfied the London Chamber of Commerce and the Merchants' Association of New York. Sir Evelyn then gave figures of the increase of wages since the war and turning to the new telephone rates, he stated the objections to flat and measured rates. He furnished a list of countries where the flat rate has been abolished and condemned, and gave a sketch of the organisation of the telephone service.

On April 11, Sir E. MURRAY resumed his explanation of the organisation of the Post Office Administration, and gave further information as to war bonus and pension liability. Sir HENRY BUNBURY (Comptroller and Accountant-General) accompanied by Mr. F. J. PEARSON, then gave evidence on telephone expenditure, depreciation fund, life of plant, and wages, explaining to the Committee the maximum wage paid to telephonists. He said that the scales of pay for labour in the Post Office was "not widely out of relation to what the Ministry of Labour report about industry in general."

On April 13, Sir HENRY resumed his explanations of overhead charges, renewals, depreciation and wages.

April 18.—Mr. H. C. ROBBINS, of the Press Association, was examined. He stated the case for the large user and gave figures showing the increase which a subscriber making 5,000, 6,000, and 10,000 calls would have to pay under the new rates—in the case of London 94, 123, and 242 per cent. respectively. He complained of the abolition of the flat rate, and the diminution of the London area, and the increase of the trunk rates. He also gave his views on the carrying capacity of a line, and quoted an opinion that the National Telephone Co. was more business-like than the Post Office. He had, however, never joined in denunciation of the Post Office service, which he thought was as good as that of the National Co. He suggested an all-round percentage addition to the present rates. He thought the trend of the Administration was to restrict use, and that one supervisor to eight telephonists was too many.

On April 20 Mr. C. R. S. KIRKPATRICK gave evidence on behalf of the Port of London Authority, opposed the abolition of the flat rate, and complained of the enormously increased cost of the service to the Port Authority. He claimed that Tilbury, which was part of the Port of London, should not be excluded from the London area, even if the loss involved had to be borne by other subscribers.

April 27.—Sir WM. NOBLE, Engineer-in-Chief of the Post Office, accompanied by Major PURVES, was examined. They described to the Committee the division of work in the Engineer-in-Chief's office, the scope of the Research section and the encouragement given to inventions. After showing how that office kept in touch with progress in foreign countries, they explained the c sts in which the new rates are based, and why the cost per call was practically the same in the case of large and small users. The recent development of thermionic valves was mentioned, but it was pointed out that they could not be used with advantage on light temporary lines erected for Admiralty purposes during the War. The relation of cost to development was explained, and information given on the cost of switchboards.

On April 28, further information was supplied on Organisation and Research Work. The question of a fall in prices and wages was considered, and the Committee were assured that the rates would fall when costs came down. The Chairman commented on the ratio of the wages paid to skilled workmen and to telephonists. The system of dealing with correspondence was explained, and information was given to the Committee regarding automatic exchanges, the loss on the trunk lines, the debiting of Post Office accounts with war plant, and the possibilities of rural development. It was stated that American farmers run and maintain their own lines, which could thus be done more cheaply than by sending men from distant towns to do the work. Major Purves doubted whether it was practical politics to allow farmers to run and maintain their own lines here and whether farmers would rise to the occasion.

On May 2, the Engineer-in-Chief's evidence was continued. Major PURVES dealt with cases of alleged waste of time by Post Office men, who, according to communications which had been received, were employed in large numbers to carry out small jobs. Satisfactory explanations were given in all cases, the fact being that besides the Post Office men present there were employees of Gas and Electric Light Companies, of private contractors, or of the London County Council engaged at the points about which complaints were made. Sir WM. NOBLE gave figures of the cost of automatic and manual exchanges, and explained h w cost of work executed by the Post Office was checked by the cost of outside tenders. He gave further evidence of the ratio of costs to development and on the subject of depreciation.

On May 4, Mr. T. S. BROWN and Mr. W. B. SMITH were heard on behalf of the Glasgow Corporation. They suggested the return of the Glasgow system to the Corporation, and gave their opinion that they could afford service at a £5 rate rental plus 1½*d.* a call. They confessed that they had taken no expert opinion but thought that, despite the enormous rise in prices, it should be possible to give service at that rate. The Chairman in summarising their evidence said that it was based on opinion rather than on substantial facts, and that their experience was born of different conditions from those at present existing.

On May 9, Mr. A. J. HOBSON and Sir A. SHIRLEY BENN gave evidence on behalf of the Association of Chambers of Commerce. They suggested transferring the Post Office system to the care of a Telephone Authority, but had not any detailed scheme to offer the Committee. They thought the large user should be charged at a more favo rable rate than the small user, because "the pr portion the latter makes of the user of the capital is less." It was explained that the traffic of great and small subscribers was so distributed on the board that each operator dealt with the same amount and therefore that the cost of operating all calls was the same. Mr. HOBSON, however, claimed that the cost of handling calls was not confined to switchboard work. Sir SHIRLEY BENN suggested that ample funds ought to be provided for the research department.

TELEGRAPHIC MEMORABILIA.

THE following extract from the "Current Topics" of our contemporary *Electricity*, should prove interesting to every reader of these pages. The warning note in the lines which I have taken the liberty of italicising is much needed at the present time when each and every boosted stunt is hailed as a practical success applicable to every-day working and conditions. One has no desire to belittle the results of effective organisation added to those of months and even years of study and research. It is well, however, that the really scientific press should at least raise a warning finger against that type of advertisement which leads the general public to expect the results of the latest developments of the laboratory and those of carefully nursed experiments to be available for common every-day use a week or two after their announcement. "Elektron" the writer of the paragraphs, says:—

> "The recently reported 5,500 miles telephone conversation, although a typical American "stunt," is, nevertheless, of historical interest as demonstrating what the future may hold in the way of transcontinental and international telephony. Given the necessary organisation, apparatus, and suitable cable connexions there is now practically no limit to the possibilities of telephoning half round the world. Wireless can bridge the gaps left in air and cable routes, whilst the thermionic valve repeater provides the necessary additional energy at intermediate points to boost up the initially feeble telephonic currents. *It must not, however, be inferred that these facilities for long-distance telephony will soon be available to all telephone users who care to pay the special trunk fees, which would have to be very heavy indeed to cover the enormous cost of such an organised scheme as that above referred to.*
>
> "It is a comparatively simple, though expensive matter for a powerful organisation like the American Telephone and Telegraph Company to pre-arrange a set of conditions along its various air line and cable routes extending across the Continent so that theoretical possibilities, worked out in the laboratory in detail, can be put to actual test as indicated. Such an experiment involves whole-hearted co-operation between all the responsible officials along the route, and a good deal of preliminary experimental work at the various links to

Digitized by Google

ensure success on the date fixed for the demonstration. Great credit is due to Colonel Carty, vice-president and chief engineer of the company, and his staff of assistants for their achievement, and when *in later years*, perhaps, we speak in London to our friends and business *confrères* at Johannesburg, Bombay, or Hong-Kong, we shall have the A.T. and T. to thank for the inception of the idea."

It is gratifying to discover that in matters electrical and engineering this country is still able to lead the way, at least along certain well-defined directions The *Manchester Guardian* recently stated that according to Mr. Pearce, chairman of the Manchester Electricity Committee, and City Electrical Engineer, who had paid a visit of careful enquiry into the large electricity generating stations of the U.S.A. on the spot, these large generating sets have not been a complete success, and there is a tendency to proceed more slowly and generate with sets of a lower capacity. Consequent upon this visit the responsible engineers of Cottonopolis have decided to continue with the Barton scheme as already designed, without practically a single change, certainly without alterations of a fundamental character.

It may be accepted perhaps as a sign that the writer is approaching the stage of sere and yellow leaf, but taking all risks of this character, one is fain to admit one's leaning towards the pensioned officers of the telegraphs together with that interest in the manner in which they spend the evening of their days. Two letters are in front of me. Both indicate hobbies not easily equalled. Says one, "I am busy with Latin just now, picking up the threads. . . . It has always been my dream to read Horace and Catullus in the original." The other, with his heart still interested in telegraphia and his study of and interest in astronomy still unabated, interrogates:—"Have you or Marconi heard anything of the Martians, or Lunarians or Saturnians yet? Why not try wireless to Orion? It would only take 100,000 years to obtain a reply to your first signal, that is, taking the velocity of electricity to be approximately that of light, about fifty thousand years on the outward journey and the same on the return. There would be quite a comfortable time in between to go out and obtain a little light refreshment!" I have taken the trouble to check these figures and staggering as they may appear they are without doubt well within the most modern estimates. Sir Norman Lockyer says that the time taken for light to travel from the Orion constellation (light and electricity may be considered identical in speed and somewhere in the neighbourhood of 11 to 12 million miles per minute), "cannot be less than sixty thousand years."

It is understood that the re-decoration and restoration of the home of the Institution of Electrical Engineers on the Victoria Embankment are rapidly approaching completion. One looks wistfully towards the possibility of the London Telephone and Telegraph Society resuming their monthly meetings in one of its commodious halls, so well adapted for gatherings of this and kindred character.

From my South African post-bag it is gathered that no less than seven illuminating systems were tried in the Cape Town C.T.O. before a satisfactory one was obtained. Kimberley reported that a satisfactory system had been tried at that office, but had been dismantled owing to its high cost.

The telephone and not the telegraph was responsible for the following on the day of the Football Final: "The King shook his feet in the sand," which, being translated, dear readers, meant, "the King took his seat in the stand!" It must have been the same telephone which directed an adjutant to "Arrest Private Jones, 21421, *have some tea*, report, &c." "Absentee" being the term by which the three more hospitable words had been supplanted.

Readers will doubtless have noted the new feature of the Calendar of Coming Events which commenced in last month's issue, page 130. Secretaries of Post Office educative, social, philanthropic and recreative organisations would oblige by furnishing a one-line announcement by not later than the 15th of each month prior to the nominal date of publication.

The retirement of Mr. Tinson was referred to in last issue by those specially connected with the telegraph school in which sphere he so ably completed the closing term of his service. It will surely not be amiss, though slightly belated, if on behalf of the many friends and colleagues in the wider sphere of the C.T.O. itself expression is here given to the goodwill and best wishes which follow him into retirement.

La bénédiction nuptiale était donnée en l'englise de St. Laurent Anvers à 11 heures le 20 Avril 1921 au mariage de Albert (fils de Monsieur et Madame Collignon) avec Mademoiselle Adrienne Anthonis.

Regret is expressed that direct telegraphic communication between London and Rome should be interrupted even temporarily, and it is hoped that this important line linking up the two capital cities will ere long be re-established.

The *Court Journal* for May 13 announces that the following officers lately attached to the C.T.O. have been authorised to receive the Imperial Service Medal, viz.:—

Messrs. Louis V. Desous and William G. Foord, Overseers; also Messrs. Archibald H. Hunter and Albion G. Tomkins, Telegraphists.

The *Electrotechnische Zeitschrift* gives the following interesting items regarding some of the latest practical developments of wireless telegraphy. During recent wireless trials with the high-speed Siemens printing telegraph system between Berlin and Leipzig, which covered a period of five hours, all the available traffic between these two cities was disposed of. The rate of working during this period attained the remarkable figure of 120 telegrams per hour. The length of the telegrams is not stated. The same journal notes that a very powerful wireless station has been erected at Banjica near Belgrade, Yougoslavia, and that the Japanese Government has constructed a high-power station at Haranomachi, Fukushimaken for a projected communication with the U.S.A.

According to the *Journal Télégraphique* of Berne, the Swiss Government is arranging to erect a powerful station at Münchenbuchsee, near Berne, with a range of 2,000 kilometres. The station will be exploited by a private company, the Government assuring the latter a sum sufficient to pay interest at the rate of 6 per cent. on the capital involved. If, however, the profits permit of a higher dividend than this figure the company is under an obligation of sharing the surplus with the administration.

By a curious coincidence, in the same journal it is noticed that the number of periodicals reviewed dealing with telegraph and telephone subjects and written in the English and German languages, is exactly equal. In the case of our own tongue this includes the U.S.A., and in that of Germany includes Austrian issues. France comes next on the list, but includes Belgian publications.

Herr K. W. Wagner, in *Elektrotechnik und Maschinenbau*, gives some interesting particulars of experiments which he carried out for the German Government in 1919 on the 400 kilometre Berlin-Hanover circuit, in which utilising high-frequency currents (*i.e.*, of a frequency of 100,000 and over) successful trials whereby three simultaneous conversations were rendered possible over the same pair of telephone wires. High-frequency multiplex telegraphy is also being developed, Siemens at a speed of 800 to 900 words per minute being used. It is stated that between Berlin and Frankfort six telegrams were simultaneously dealt with over the ordinary single conductor circuit. It will be recalled that Squier of the U.S.A. has been independently working on this subject for some years with no small measure of success, as also Rühmer in Germany.

A small delegation from the Belgian telegraph administration visited the C.T.O. London during last month and spent a whole week with us, observing investigating and noting the special telegraphic features of that great centre. They were evidently pleased with their visit, and it is hoped that they have taken back with them information which will prove of unmistakable utility to their industrious and enterprising country. J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

Engineering Department Dinner.

THERE are two classes that attend public dinners—those who go for the sake of the dinner itself, and those who go to enjoy the words and music and to greet old friends. Both classes were amply catered for at the Annual Dinner of the Engineering Department held under the Chairmanship of Sir W. Noble at the Connaught Rooms, on April 22. An excellent dinner, excellently served, a musical programme not too long to risk the charge of tediousness, and interesting speeches combined to make a very pleasant evening.

The toast of the Post Office Engineering Department was proposed by the Right Hon. Pike Pease, M.P., in his usual fluent style, and seconded by Sir H. Bunbury, K.C.B., and was replied to by Sir W. Noble. The toast of the visitors was proposed by Mr. A. Moir, O.B.E., who, in a very pleasing speech, skilfully worked in appropriate references to the principal guests present. Mr. Ll. B. Atkinson (President, Institution of Electrical Engineers) replied on behalf of the visitors. The sterling qualities of Sir W. Noble were gracefully alluded to by Sir E. Murray in proposing the toast of the Chairman. The gathering afforded a welcome opportunity to members of the P.O. Engineering staff to greet old friends from other branches of the Service and profession and from commercial undertakings with which the Post Office have business relations.

A Common Sense Decision.

The chief impression gained in listening to Mr. Crum's paper on "Some Features of the American Telephone Service" on April 18, was that the conditions in the United States of America all favour the use and development of the telephone as a means of communication. We were told that even the charlady loses caste unless she has a line. The chief difference between America and this country appears to be that whereas in the former everyone does his utmost to facilitate the development of the telephone service, in the latter every possible difficulty is put in the way of the business being conducted economically and expanded rapidly. Fanciful objections are raised here to the erection of poles in cases where the cost of underground plant cannot be justified. Apparently in America the presence of poles in the streets is taken as an indication of progressiveness. Incidentally, judging from illustrations in the technical journals, American poles are not always so upright as American citizens.

As an indication of the kind of difficulty met with in this kingdom the following case is quoted :—

A pole had stood for 10 years on a piece of waste land in a London suburb. The freehold of the land changed hands and an application was made immediately by the new owner for increased payment on the score of the depreciation of the value of the sovereign. As the Department would have been put to heavy expense to move the pole, and as the owner of the land was apparently suffering no loss by its presence, the case was taken to arbitration and was heard on April 27. The Judge was in sympathy with the Department's efforts to keep down working costs and ruled that as the freeholder was not suffering any apparent loss through the presence of the pole on his land, the rental would be reduced to a purely nominal sum, and the costs borne by the wayleave grantor. In summing up the judge paid tribute to the very fair and courteous manner in which Department's officials had dealt with the matter. When laying plant the first considerations of the Department are efficiency and economy. Although the maintenance charges are less for underground than for overground plant, other factors come into play which militate against the use of the former in all cases. Whenever the prospective development is such as to justify the high first cost of underground being incurred this type of plant is laid. When it is clear that the financial advantages are in favour of overground plant then the Department looks to the local authority or owner of the soil to co-operate in forwarding the national work of providing an efficient service at the lowest possible outlay by granting the necessary facilities without attempts to impose onerous conditions. If such co-operation is not forthcoming the American standard of one telephone per eight inhabitants will never be reached in this country.

Excavations in Ludgate Hill.

Although the lot of the engineer who endeavours to find space for telephone pipes in the congested streets of London may not be a very enviable one, yet there are compensations, especially to one who has a taste for history or archaeology. Some of the "finds" are exceedingly interesting. These finds include Saxon, Roman, and early English relics.

Ludgate Hill has just been opened in order to lay additional pipes, and at a depth of twelve or fourteen feet the surface of the original Ludgate Hill was discovered. It was paved with large stones which bore unmistakeable evidence of having been rounded by running water. At the bottom of the hill was revealed a stone arch which evidently formed part of the bridge which crossed the Fleet River at this point. Remains of old houses were also found, and there is reason to think that subsequent to the Great Fire the level of the road was raised by filling in the debris of the destroyed houses.

It is rarely that a street is opened within half a mile of Ludgate Circus without revealing some objects which take the mind back to the days when London was a small town constructed in the midst of a swamp. Pictures are conjured up of Romans striding haughtily past crowds of half-naked and sullen islanders or of dandies with slashed doublets and silken hose picking their way daintily through streets filled with garbage. From time to time human bones are discovered, showing that what is now a busy and prosperous thoroughfare was once the site of a churchyard or cemetery. The thought irresistibly occurs, "Can these dry bones live?" If it were possible to breathe life into these old bones to rehabitate them in warm living flesh, to clothe them and then to conduct them to a modern telephone exchange, there would soon be another death from shock, even if our mediaeval friend survived the journey on a vehicle without the need of horses, the only perceptible means of propulsion being noise and smell.

Power Supply for Telegraph Offices.

The cost of maintaining primary cells for working busy telegraph sets is a serious item, and in order to reduce this cost a scheme is just being completed for supplying offices within a short distance of the G.P.O. West with power from the C.T.O. For this purpose a six-core rubber-covered and lead-sheathed cable has been laid in the Fleet Street area on the ring main system. The voltage of the supply is 40, 80 and 120 positive and negative. Switches have been inserted at suitable points so that if a fault should develop the section affected can be isolated without interfering with the supply to other sections.

Pneumatic Tubes.

There is a "certain livelines" in the pneumatic tube schemes just now. A tube has recently been completed between the C.T.O. and Mt. Pleasant. This tube is suspended from the roof of the tunnel which has been constructed for the purpose of carrying mails. A number of other schemes for the extension of the pneumatic tube system are also being dealt with.

Electrophone Service.

In most services there are occasions when abnormal demands are experienced. Sunday, May 8, proved to be such an one at the Electrophone Exchange. The reason was that Madame Melba was singing at the Albert Hall. Thanks to the thermionic valve amplifier no less than 600 subscribers were enabled to listen to the famous singer.

Everyone who knows the Managing Director of the Electrophone Co., Mr. H. J. S. Booth, will learn with regret that he is at present dangerously ill, having some 13 weeks ago had a stroke causing paralysis of the left side. The doctors are hopeful of his recovery. It is the wish of his friends that he will be back at business in completely restored health in the near future.

Wireless Installations.

Reference was made in the March issue of this JOURNAL to the installation of a demonstration set at the District Apparatus School, Denman Street.

An aerial has now been erected on the roof of the Superintending Engineer's Office, and the apparatus is now in operation.

Those officers selected to undergo the course of instruction are greatly appreciating the privilege.

Post Office Engineers as Public Speakers.

Sir William Noble's paper was read and discussed before a crowded audience at Manchester recently, and a writer in the *Electrician* in commenting on the discussion states :—

> "The fluency of speech of many Post Office Engineers was a feature of the discussion, ascribed privately by one of their number to the practice they have acquired in preparing official minutes, or is the real reason the necessity they have been uuder recently of explaining the shortcomings of the telephone system."

Post Office Engineers have nothing to apologise for. The reason for this fluency is well-known to the engineers themselves.

An Echo of the Strike.

During the strike one supervising officer received the following laconic message :—

> "Sorry cannot attend to-day. Have not arrived home yesterday."

SECRETARY'S OFFICE CRICKET CLUB.

The captain for the present season is Mr. G. O. Wood, the vice-captain Mr. P. P. Cove, and the secretary and treasurer, Mr. F. J. Pearce. The club is at present without a ground, but hopes by the middle of June to be in possession of one at Walthamstow within half-an-hour of the office. The first match was played at Richmond on May 11 against the Ministry of Labour and won by 7 wickets.

LONDON TELEPHONE SERVICE NOTES.

South London Hospital for Women.

THE splendid success of the Bazaar organised by the women of our London exchanges in December last has been followed by a further notable achievement. During the two days of the bazaar a sum exceeding £2,000 was raised for the South London Hospital for Women. After endowing two beds, one medical and one surgical, a balance of about £400 remained and this has been augmented by subscriptions from the staff to a total of £500. This latter sum is to be used for the endowment of a child's cot. When Miss Heap first suggested the raising of a sum of money for the Hospital the objective was £1,000 for the endowment of one bed. That sum was not mentioned without a measure of hesitancy notwithstanding the acknowledged generosity of the staff. The magnificent conclusion to the effort is sufficient satisfaction to all who worked and subscribed with such enthusiasm. It is a fitting compliment to Miss Heap, who will shortly be retiring from the active list of the L.T.S. establishment, that the staff has decided that the beds shall be dedicated in her name. A photograph of one of the wards of the Hospital is reproduced below.

Queen Mary Ward, South London Hospital for Women.

Telephone and Telegraph Society.

The paper read by Mr. Crum at the final meeting of the Society afforded an opportunity for the discussion of certain features of the American telephone system. A large measure of the discussion centred around the comparison of the telephone development in New York and London, in which London appears to such disadvantage. The reason for the growth of the telephone habit in America's large cities has been much discussed in telephone circles, but the present occasion shed little new light on the question. The curves produced by Mr. Crum comparing the diurnal distribution of the traffic on both sides of the Atlantic are substantial evidence of the difference in the telephone habit in the two countries. The absence of prominent rush period peaks in the American curve and the almost ideal condition which thus exists from the point of view of staff costs seems almost incredible to telephone experts in this country. No satisfactory explanation of the difference in habit is yet forthcoming unless it be that in America incomes generally may provide a larger margin for what may be regarded as non-essentials than is the case in this country. The large number of party lines existing in America in contrast with the comparatively small number in the British Isles is indicative of the greater sociability of the American people and the attitude of seclusiveness which sticks to the Britisher.

Some surprise was occasioned by the statement that in certain exchanges in America enquiries for the time represented as much as 5 per cent. of the traffic. Mr. Crum was unable to give the reason for so large a number of calls of this nature.

Prior to the reading of the paper the business of the Annual General Meeting was transacted. The balance sheet shows the Society to be in a strong position financially. In number of members, however, the position cannot be regarded with satisfaction as the total membership was only 339. Reasons for this condition will doubtless be sought before the next session. Discontinuance of the practice of circulating the papers prior to the meetings is not conducive to the maximum of discussion, and thereby detracts from the value and interest of the meetings, and this may be another cause of the waning enthusiasm towards the Society.

Langham Choral Society.

The concert given at the Queen's Hall on May 10 marked the end of the first year of the Society's existence. An operatic programme was presented such as could not fail to attract music lovers and the success achieved has undoubtedly enhanced the reputation of the Society. The programme comprised :—

Overture—"Tannhäuser"	*Wagner*
Duet Scena (Aida and Radames)—"Aida"	*Verdi*
Introduction and Wedding Procession—"Le Cogg D'or"	*Rimsky-Korsakow*
Choral Scena—"Prince Igor"	*Borodine*
Wotan's Farewell and Firespell—"The Valkyries"	*Wagner*
Prelude—"Tristan and Isolde"	*Wagner*
"Ride of the Valkyries"—"The Valkyries"	*Wagner*
Complete concert performance of "Cavalleria Rusticana"	*Mascagni*
"Marche Hongroise"—"Faust"	*Berlioz*

There was a large and appreciative audience and their commendations are reflected in the favourable reports which have appeared in the Press.

Egyptian Service.

As an interesting comparison of English and Egyptian conditions we borrow from our contemporary, the *Post Office Electrical Engineers' Journal*, the following details of the service in Cairo and Alexandria, supplied by Mr. M. J. Bowes, Traffic Superintendent, Egyptian State Telephones :—

	Month of December. Cairo.	Month of December. Alexandria.
Answer	3.5 secs.	3.9 secs.
Clear	5.3 secs.	4.0 secs.
Per cent. answered in 5 secs. or less ...	83.3	82.9
" " " 10 "	95.5	96.5
" " " 20 "	99.4	99.7
Time taken to answer flash	4.0 secs.	3.1 secs.
Per cent. no reply	2.7	2.1
Per cent. number engaged	11.2	10.5
Time taken to report no reply...	102.0 secs.	85.1 secs.

The operators are required to operate in four languages, viz., Arabic, Italian, French and English. The proportion of each is :—

Arabic	40 per cent.
Italian	30 per cent.
French	25 per cent.
English	5 per cent.

English is the standard language for all order wire and junction working

Phonetic Similarity.

Overheard at Prince's House *Hostel*. "This 'ere building's being got ready for *hostile* purposes."

Bromley Exchange.

From the proceeds of a concert held on April 26 the staff of the Bromley Exchange have sent a donation of £14 to the Hospital Saturday Fund in response to the special appeal.

Sports.

On Tuesday, April 19, the football section of the *East Social and Sports Club* played a match *versus* the L.C.C. Fire Brigade (Brunswick Road) for the Mayor of Poplar's Fund for relief of distress amongst the unemployed of Poplar. The match was attended by the Mayor, Mayoress and Councillors, also by the Sectional Engineer, Mr. A. H. Wood, and the Assistant Engineer, Mr. F. G. Brown, and all the supervising staff of East, Stratford, Walthamstow and East Ham Exchanges. The match was full of interest, the Eastonians winning by 5 goals to 2. At the conclusion of the match the Mayor presented medals to the winning team, and on behalf of the East Social and Sports Club to the losing team. A vote of thanks to the Mayor was moved by Mr. A. H. Wood in a very neat speech. The ball with which the match was played was auctioned on the ground and realised the sum of £7 10*s*. The East Social and Sports Club were responsible for the arrangements. This club embraces the whole of the staffs in the East Exchange area, its objects are to promote sports and social intercourse between the staffs. At present it has upwards of 200 members, and is split into sections as follows:—Football, cricket, tennis, swimming, cycling and socials. Throughout the past season a dancing class has been run, and thanks to the able assistance of the telephonists several of the male staff have been taught dancing. The cycling section have just started their runs and have been rewarded with a good attendance of both the female and male staffs. We would like to hear from any section of the staffs who could oblige with cricket and swimming fixtures. The Hon. Secretary is Mr. A. Williamson, 4, Rounton Road, Bow, E.3, or East Exchange.

* * * *

The committee of the *Belgrave Social and Sports Club*, L.T.S., have arranged a char-a-banc trip to Tunbridge Wells on June 19.

In connexion with the club the lady members will meet for swimming every Monday throughout the season at Hornsey Road Baths between the hour of 6 and 7 o'clock.

City Traffic District.

Under the auspices of the Mansfield House Settlement the staffs of the Exchanges in the City Traffic District entertained 250 children of ages ranging from six to nine years and one baby at the Fairbairn Hall, Canning Town, on April 23 last. The ladies of the Bank, Central, City and Trunk Exchanges and the Carter Lane School prepared and served at flower-bedecked tables.

Digitized by Google

After tea sweets were distributed and a singing competition was held. Ten little girls and ten little boys selected from at least a hundred applicants competed. A show of hands decided the order of merit, which was suitably rewarded, the boys voting on the girls' efforts and *vice versa*. The honours generally fell where deserved, but not always. The first prize for boys fell to a nice little boy with ruddy cheeks and a clean blue jumper whose looks were obviously better than his voice.

Amid great excitement the ventriloquist and marionettes arrived, and thenceforward the children were all "eyes and ears." How they laughed and yelled when Robinson Crusoe danced and when the roller skater "came a purler"! How quiet they were when the ventriloquist asked them to nod at him when his dummy endeavoured to pick his pocket!

The giant bonbon, so tastefully prepared by Miss Bigger and her colleauges on the Carter Lane School staff, was next pulled, and the children filed up and dipped for toys in its capacious pockets. An orange and a new penny were handed to the children as a parting gift, and both children and helpers dispersed to their homes feeling that all had had a happy afternoon. The children's cheers and their happy faces were an ample reward for the efforts made on their behalf.

Throughout the afternoon the chief supervisors of the exchanges were present and actively assisted in the entertainment of the children. The funds for the entertainment were subscribed by the exchange staffs in the City District, and the arrangements made reflect great credit upon Miss Ruffy and Miss Cureton, of the Trunk Exchange who, with Capt. Berry, were primarily responsible for the success of the afternoon.

It was intended to give 250 of the older children in the neighbourhood of Canning Town a day in Hainault Forest on May 21, but owing to transport difficulties it has been necessary to cancel the arrangements made.

The funds will probably be devoted to sending the boys and girls to the holiday camps arranged by the Mansfield House Settlement.

INTER-BRANCH GOLF MATCH.

On the kind invitation of Sir Andrew Ogilvie, formerly Second Secretary of the Post Office, 15 officers representing the Telegraph, Telephone, Home Mails, and Foreign and Colonial Branches of the Secretary's Office, joined with him in a golf match on the afternoon of the King's Birthday Holiday. The match took place on the charming Surrey Links at Woking, and resulted in a victory for Sir Andrew's own particular branches—the Telegraph and Telephone—by 3½ points, each match counting as 1 point and a victory on the byes as ¼ point.

The detailed scores were :—

T. and T. Branches.		*H.M. and F. and C. Branches.*	
SINGLES.			
J. Curran	1¼	D. A. Hogg	0
Sir A. Ogilvie	0	H. Darby	1
de G. Gavey	1	D. J. Lidbury	0

	7¾		4¼

The outing and Sir Andrew Ogilvie's hospitality were much enjoyed by his former colleagues.

PERSONALIA.

LONDON TELEPHONE STAFF.

Resignations on account of marriage.

Miss M. A. MANSELL, Assistant Supervisor, Class II, of Putney Exchange.
Miss E. M. DREW, Assistant Supervisor, Class II, of Avenue Exchange.
Miss M. E. DAVIES, Telephonist, of Avenue Exchange.
Miss D. Z. M. CLARKE, Telephonist, of Avenue Exchange.
Miss C. M. WICKHAM, Telephonist, of Museum Exchange.
Miss M. E. A. TOETTCHER, Telephonist, of New Cross Exchange.
Miss G. J. SWALLOW, Telephonist, of Woolwich Exchange.
Miss H. CANDELIN, Telephonist, of Trunk Exchange.
Miss D. L. FOSTER, Telephonist, of Trunk Exchange.
Miss E. FORREST, Telephonist, of Trunk Exchange.
Miss L. R. BEER, Telephonist, of Trunk Exchange.

PROVINCIAL.

Mr. C. A. GATE, Assistant Traffic Superintendent, Class I, Blackburn, was presented by his colleagues with a case of pipes as a mark of esteem on the occasion of his transfer to Norwich as Traffic Superintendent, on April 9, 1921.

Mr. S. A. YOUNG, Contract Manager, Blackburn, was presented with a smoker's outfit on the occasion of his transfer to Belfast as Contract Manager on April 16, 1921.

Mr. W. MORAN, Clerical Officer, District Manager's Office, Telephones, Blackburn, was presented with an attaché case by his colleagues on his appointment to the Customs and Excise at Chester on April 30, 1921.

Miss VASS, who has been for several years in the service of the Elgin Telephone Exchange, was on Thursday, on the occasion of her retirement from night service, made the recipient of a wallet containing £50. Col. C. J. Johnston, of Lesmurdie, who made the presentation, referred in glowing terms to Miss Vass's valuable work.

(Photo by R. C. Whyte, T.N.S.)

THE THREADNEEDLE STREET P.O.

This historic building is about to be demolished and a new office erected. It will be noticed that on the face of the building are the words "Telegraph Station," the names of the four continents, and the name of the Company, "The British & Irish Magnetic Telegraph Company." The encircled globe over the main entrance will be noticed.

HISTORY OF THE ANGLO-CONTINENTAL TELEPHONE SERVICE.

(*Continued from page* 135.)

IT had been proposed by means of the Lille circuit to serve not only the North of France, but eventually Brussels. Experiments which had been carried out on the Anglo-French lines early in the year 1897 showed that satisfactory speech could be obtained between London and Brussels and even Rotterdam. Indeed, the establishment of telephonic communication between London and Brussels or Antwerp *via* Lille was agreed upon in 1900; but before the Anglo-French convention of 1902 took actual shape, Treasury sanction had been received for the provision of a direct Anglo-Belgian cable. A contract for laying the cable was placed in 1901. On laying it, however, faults were discovered in certain portions of the cable, and it had ultimately to be entirely rejected. Arrangements were made with the contractor, with the approval of the Belgian Administration, for the manufacture and laying of an entirely new cable in 1902. The cable which contained 2 circuits (one of which was superimposed for telegraph working) was laid between St. Margaret's and La Panne in April, 1902, and communication between London and Brussels was opened in June, 1903, and extended to other towns in both countries in October of the same year. The total cost of the cable was £31,374, of which the Belgian Government paid half, viz., £15,687; the land lines cost £16,733, whilst its maintenance was undertaken by Great Britain at the joint cost of both countries. The cable, which was 47.28 knots in length, contained a weight of 160 lbs. of copper and 300 lbs. gutta percha per nautical mile. A convention between Belgium and the United Kingdom was signed at Brussels on Nov. 21, 1902, fixing the tariff between those places in Belgium and England and Wales which could communicate by telephone at 10 francs.

As the traffic between England and France steadily increased, the provision of 4 additional circuits was suggested to the French Government in June, 1907, and it was agreed that each Administration should lay another cable. The contract for the British cable was let to Messrs. Siemens, and a coil-loaded cable containing 2 circuits was laid between Gris-Nez and Abbot's Cliff in 1910. The French cable was laid between the same points in 1912. It also contained 2 circuits, was continuously loaded, and weighed 300 lbs. copper and 300 lbs. gutta percha to the nautical mile. Increasing traffic also necessitated the provision of additional circuits to Belgium, and in 1911 a new coil-loaded cable containing 2 circuits was laid by Great Britain between St. Margaret's and La Panne at the joint expense of both countries.

After the provision of the two additional loaded cables to France, a new agreement with that country was executed on Feb. 5, 1912, under which the charge for calls from London to Paris was reduced from 8*s.* to 4*s.*, and both countries each divided into 3 zones, the charges between which were correspondingly lower than the rates then current. The night charges were also reduced, and a system of night subscription calls was introduced. By 1913 the service was extended to all the principal towns in England and to some 250 places in France.

As soon as these cables were laid, speech trials between London, Geneva and Basle were satisfactorily held, and as the French were willing to facilitate telephonic communication with Switzerland *via* France, no time was lost in negotiating an agreement between the three countries. It was signed towards the end of 1913, and service between London, Basle, Geneva and Lausanne was opened on Jan. 1, 1914. It was withdrawn from the public along with all Anglo-Continental telephone service on the outbreak of war. For the same cause the projected Anglo-Dutch service did not come to fruition. Agreement with the Netherlands Government was reached, the rates were fixed and the cable (to be laid between Aldeburgh and Domburg in Zealand) was actually in process of manufacture when war supervened. The prospect of laying it across the North Sea in that troubled period was remote, and the cable when completed was used to supply Admiralty and War Office communications across the Channel. The war also put an end to the negotiations which had been going on with the German Government relative to the provision of a direct telephonic communication, either by a cable to Emden, which that Government had suggested in 1910, or alternatively by a cable to Walcheren and overland lines to Germany *via* Holland.

Digitized by Google

The average monthly Anglo-French telephone traffic, which as we have seen averaged 3,018 calls a month in 1892, and 4,764 in 1895, reached a monthly average of 7,787 in the year ended March 31 1912, 9,867 in 1913, and 11,735 in 1914. In the July immediately before the commencement of hostilities 19,963 calls passed between England and France over the 9 circuits then working.

II.—(1914-1919).

During the early part of the war the whole of the Anglo-Continental telephone circuits were reserved for the use of the Admiralty, the War Office and the War Cabinet, except only one circuit from the London Trunk Exchange to Paris and one to Boulogne, and even the use of these was restricted to calls on official business, either from Government offices or from the offices of firms employed on Government work. The number of cables across the Channel was soon increased. Military exigencies are always for obvious reasons more rapidly satisfied than civil needs, and during four years of war no less than 15 additional channels of speech were provided between England and France, while 23 years had been required to bring into being the existing nine. On the outbreak of war most of the latter were, as already stated, set aside for communication between the War Office and the Base Offices and the Headquarters of the Expeditionary Force, but when the British Army moved into Picardy and Western Belgium after the Battle of the Marne it became necessary to provide direct communication with that district also, and circuits were promptly run to the cable heads at the French coast towns. On the occupation of Belgium by the Germans one of the Anglo-Belgian cables was diverted to Dunkirk, but the older unloaded cable developed a fault and was not repaired during the course of the war. Three additional circuits to Dunkirk were provided by a new cable from Dover in 1917 and used partly for Admiralty purposes and partly to afford communication with the headquarters of the Royal Naval Air Service in France in order that information and assistance might be obtained in connexion with enemy air raids on England.

The difficulties involved in immerging cables in the English Channel in war time under the constant threat of peril in the heavens above and in the waters beneath can readily be imagined, but the zeal and courage of the engineers and their assistants were always equal to the occasion. The following extract from a report of the Engineer-in-Chief in the laying of the Dunkirk cable gives some indication of the dangers involved :—"The landing of the shore end at Dunkirk gave rise to considerable difficulties owing to the rough but shallow water, in which even a barge was unable to work. As a consequence sailors had to be employed to drag the cable over a bank for a distance of half-a-mile. An attempt was made to do this with 250 men but the number had to be increased to 850 before the operation could be performed. While this work was in hand an aerial combat between British and German aircraft was in progress overhead. The final operation in putting the cable through was the joining of the British and French sections in mid-Channel. The *Mersey* tried to make the joint last night but the weather was too boisterous. Fortunately it moderated sufficiently to enable the vessel to leave the harbour at 12.30 p.m. to-day, pick up the two ends, and join them together."

In the December of the same year a cable containing 3 circuits (one superimposed) was laid between Dover and Sangatte and provided the naval and military authorities with additional circuits to Calais, and connected the War Office with Versailles. By this time the lines of communication in the North of France formed an extensive trunk wire system by means of which G.H.Q. was not only directly connected with England *via* Calais, Boulogne and Dunkirk, but also with the various army headquarters and with Paris.

In May, 1918, two cables were laid between Dungeness and Audrecelles, providing 6 more circuits (2 by superimposition) and were used chiefly in connexion with the Dover Patrol and the transport services. Thus not only were the governments in London and Paris placed in oral communication touch with each other, and the War Office with its armies in the field, but, by degrees, all arms of the service were put in possession of the incalculable advantage of regular telephonic connexion with England.

At the conclusion of the armistice the requirements of the Peace Conference at the Astoria Hotel, Paris, were served by six direct circuits from London, three of which were obtained by utilising existing lines and three by means of a further new cable between Dover and Sangatte, laid in November, 1918. At this time there were 22 circuits working between England and France, nine of which terminated at Paris, four at Dunkirk, three at Boulogne, two at Calais, one at Versailles, two at G.H.Q., and one at the American Headquarters in France. One of the G.H.Q. circuits was subsequently extended to Cologne until the re-opening of the public service to France. This constituted the only direct telephonic communication which has ever existed between England and Germany, although satisfactory speech trials were made in 1913 *via* Belgium between London, Cologne and Frankfort, and, later in the same year with Berlin.

(To be continued.)

THE SUBSCRIBER AND HIS SWITCHBOARD.

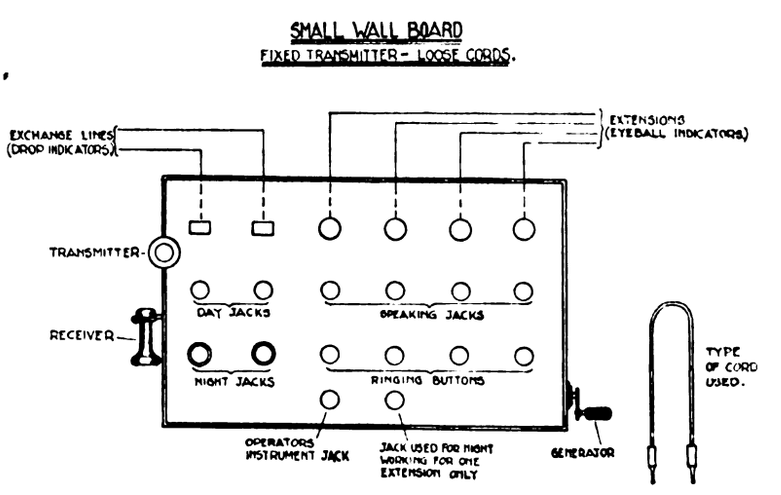
By D. HOWIESON (Glasgow).

"MAN is born unto trouble as the sparks fly upward," says the Scripture, and it would appear that those who have made the telephone business their vocation in life come in for a large share of this mundane joy. It is not only the members of the public who seem to have a telephone twist in their natures that cause the telephone officials' hair to whiten or fall out prematurely, but generally speaking the average members of the telephoning public are ignorant of the most elementary principles of modern telephony and in their lack of knowledge cause difficulties to themselves and those responsible for the service. A certain ecclesiastic of high standing visited one of our modern exchanges in order to extend his knowledge of worldly matters, and in the course of conversation stated he was surprised that the telephonists were not running about the switchroom making connexions. He was asked how he thought telephone connexions were established, and in reply stated that he imagined the operators had to run from one part of the room to another with a wire and hook it to the required subscriber's line. This method would be rather worse than a 10,000 multiple, and there would likely be a few casualties in the course of a day. Between this rather elementary point of view and that of the subscriber who imagines that by some mysterious process his connexion should be through in the twinkling of an eye with no trouble at all, there is a large field of various hypotheses as to what is really happening from the time the exchange is called until the clear is given. Of course we ignore the general skit on telephone operating contained in funny periodicals and on the stage, unless it is to laugh with the crowd at a few of our own short-comings.

A certain amount of propaganda work which we term the Education of Subscribers has been carried out, but there is still a large and ever-changing field to cover, and before we have a telephone-using public who are fully alive to the possibilities and impossibilities of the telephone much time will require to be given to this phase of the work, and every opportunity should be taken to induce subscribers to visit telephone exchanges so that their outlook on telephone matters may be enlarged.

One of the principal difficulties in connexion with the public use of telephones is the inefficient operating at subscribers' switchboards, more especially on the smaller types where there is no proper operator delegated for this work, but any member of the staff makes the connexion as circumstances permit. The trouble caused at such switchboards is incalculable, and the pity of it is that the trouble is generally thrown back on the long-suffering telephonist, who has therefore to stand the abuse for her own as well as the subscribers' errors from the present public point of view. A subscriber called at the Traffic Office one day storming and fuming that his clients were being constantly told his number was "no reply." A watch was being kept on his circuits in the exchange at the time, and while the subscriber was being interviewed word came through that no reply could be obtained on both his lines. An officer ran to the subscriber's premises which were near at hand, and found both exchange indicators down, the bell switched off, and, to make matters worse, the switchboard accommodated in a cabinet with the door shut. Needless to say, a satisfactory explanation was given to the subscriber. Before being enlightened, however, he held the view that the trouble was due to carelessness on the part of the telephonists.

Digitized by Google



Before the amalgamation of the National Telephone Company with the Post Office there were two telephone services in Glasgow, viz., the National Telephone Company, and the Post Office, and the larger users subscribed to both systems. Intercommunication between the two services was allowed. This produced some very complicated apparatus at the subscribers' premises, and when it was necessary to pay a visit to such a place when difficulty was being experienced in the exchange through the subscriber's faulty manipulation of his apparatus, the heart of the visiting officer would almost stop when he saw a goodly portion of the wall decorated with switchboards, switches and cords, a position of affairs which render the working very difficult. It was sometimes a rather awkward predicament to be in when the subscriber asked the visiting officer to show him how to work the apparatus simply, and a certain amount of ready wit had to be conjured up in order to keep the subscriber's attention off the apparatus until the eye could take in what was involved in the various items plastered on the wall. These anomalies have been almost entirely cleared out now and up-to-date switchboards have been installed with all the lines terminating on one board. An opportunity has thus been afforded to endeavour to get subscribers to take an intelligent interest in the working of their switchboards, which until this unification took place was in many cases more than could be expected owing to the complicated apparatus. In this connexion subscribers have been invited to allow their switchboard operators to be thoroughly trained where this was necessary, and in cases where there were no fixed operators, recommendations to have a properly trained person at the board have been agreed to in many cases when the advantages have been demonstrated. The result has been a distinct gain to the service as a whole, for trouble at a few subscribers' ends does not stop there but re-acts on the exchange service. Some subscribers put forward the plea that if they do not work their switchboards properly the trouble is their own. This is a fallacy, as the result is that the delinquent board becomes a minor wave centre and radiates difficulty all round, as our old friend, the stone, dropped in the pond radiates the wavelets.

On the whole there is not a great deal of trouble experienced with large subscribers' switchboards where there is a trained operator, and if any difficulty arises it can be rectified quickly. Cases of difficulty generally found in connexion with this class of switchboard are those where the operator is too busy, where the operator has to take telephone messages, in shortage of cord circuits, and in friction between the subscriber's and department's operators. The first two points usually show themselves in slow answering and clearing, and the third point in slow answering. Such cases and those of friction are reported to the Traffic Office for investigation, and a judicious interview with the subscriber, or the subscriber's operator generally puts the matter right so far as they are concerned. Cases of friction between the subscribers' operators and the exchange staff are not frequent and the relationship, if not cordial at times, is nevertheless tolerable.

With smaller subscribers' switchboards, however, as already stated, there is a considerable amount of difficulty experienced such as slow disconnexion, slow attention, too much telephoning at the switchboard, faulty manipulation and indifferent salutation. Slow disconnexion causing permanent glow in the exchange is a source of a lot of trouble, not only to the subscriber involved but also to any of his clients calling him up. In the Glasgow Central Exchange there is sufficient work in plugging up and looking after such cases to keep a telephonist employed during the busy hour. Lists of defaulting numbers have been kept and the subscribers involved have been visited, but any improvement by such means has been only temporary. The most efficacious method of combating this trouble has been to adopt what we might term worrying tactics. If a subscriber leaves a line P.G. and has another disengaged line at the time he is rung on the disengaged line and asked to clear the defaulting line, and favoured with a few aphorisms on the working of his switchboard. Some improvement has been effected by advising subscribers to set apart definitely a member of the staff to attend to the switchboard and when not required for this purpose some office work can be done sitting near the switchboard. It is surprising, however, to find some subscribers taking umbrage at what they term interference with their business. Slow answering at subscribers' switchboards is another phase of trouble frequently caused where there is no one directly responsible for the answering of the telephone. In some premises it would appear as if the telephone, being nobody's particular business, was left to look after itself. When they waken up to answer the call and obtain the "A" operator who states that there is no one on their line, they complain of false rings or cutting off. A further difficulty experienced with small switchboards is the trouble caused by the large amount of telephoning which takes place at the switchboard instead of switching through to an extension and leaving the board for switching purposes. Cases have come to light where long conversations have taken place at the switchboard and other calls have been ignored during the conversation, giving rise to unsatisfactory cases of no reply. Indeed the exchange is conveniently blamed for no reply calls in numerous similar instances and also in cases where the office staff has been out or the bell switched off. A case came under observation where a subscriber spoke for 40 minutes on one line and ignored completely all attempts to gain his attention on his second line. The connexion was maintained to see what would happen and the evidence collected overwhelmed the complainant. Faulty manipulation at the smaller boards causes some of the cut-off trouble of which we hear a lot in these days of C.B. working. The modern switchboard does not cover up the subscriber's shortcomings as did the magneto types, and the point of holding the exchange while switching through to an extension is a matter which appears beyond the judgment of certain telephone users. In listening to conversations it is surprising to find the extent to which "halloaing" goes on before actual conversation begins. Instead of boldly announcing the name of the firm it would appear to be a case of who would be last to give the name or business away. This may be Scotch "cannyness" in the case of Glasgow subscribers, but it does not make for efficiency, and many a trunk conversation could be materially reduced in time if the subscribers would announce their names when the connexion is made. It would appear that unless the voice was "weel-kent" the subscriber was diffident about giving his name away.

These are a few of the troubles associated with the working of subscribers' switchboards. It must not be taken, however, that all switchboards come under this category as there are many where the working is efficiently carried out. In such cases there is generally an absence of complaint and it often happens that a good private branch exchange operator saves us from trouble made by the exchange staff in her capacity as intermediary between the subscriber and the exchange. It is contended, however, that the number of cases of faulty working at subscribers' switchboards is much too high in these enlightened days, and that subscribers have not yet on the whole realised the importance of the proper working of telephone apparatus and the gain in quick answer and disconnexion.

The work of educating subscribers is met in this district by getting the exchanges to report cases of difficulty to the Traffic Office. An officer calls at the subscriber's premises and investigates the working, giving the necessary advice and help. An opportunity is given to the subscriber to visit his exchange accompanied by a Traffic Officer. The greater a grumbler the subscriber is, however, the less inclined is he to make the visit, as he frequently thinks that he will get a hostile reception. He is calmed, however, by the assurance that we will not give his name away. Some of the testing telephonists have been taken round subscribers' premises where there are different types of switchboards and the working thoroughly explained to them so that they can be in a position to give the subscribers any assistance in explaining the working of their boards if any difficulty comes under their notice at the testing positions. Sets of simple diagrams of subscribers' switchboards with working explanations are in course of preparation for the use of the testing telephonists. As an example of the nature of the diagrams and explanations, the following shows the small C.B. Wall Board, fixed transmitter type which is fairly common in this district.

To answer Exchange line: Insert one end of loose cord in Exchange jack and other end in Operator's instrument jack and carry on conversation.

To put Exchange line through to an extension:—Keep one end of cord in Exchange line jack; withdraw other end from Operator's speaking jack; take another pair of cords and insert one end in Operator's speaking jack and the other end in the extension jack required. Press small white button under extension jack and turn generator handle. (White button should be kept depressed while ringing with generator). When extension answers Operator explains who is calling and then withdraws plug in extension jack and inserts loose end of cord that is in Exchange jack. When conversation is finished P.B.X. Operator receives "clear" on eyeball indicator. After conversation is finished, plugs should be withdrawn at once, otherwise a P.G. is received in Exchange. One end of a cord left in an Exchange jack also causes a P.G. (permanent glow).

Extension to Extension:—Take a loose cord and insert one end in Operator's speaking jack and the other in extension calling. Procedure should then be the same as Exchange to extension. When conversation is finished, eyeball indicator "clear" is given.

Night Working. If it is necessary to leave an extension through to Exchange at night, special wiring arrangements have to be made. In such cases there is a special jack for the Exchange line and extension concerned as shown on sketch. A loose cord is inserted in the night Exchange jack and the night extension jack.

Digitized by Google

The other diagrams include large floor boards, cordless boards and the bell set 4 switch. The testing telephonists display the greatest interest in the work of educating the subscribers, and it was on their own initiative that they were taken to see the subscribers' switchboards.

Such are some of the methods taken to endeavour to bring the Telephone Service up to as high a state of efficiency as possible. The service is comparable in a small way to the position of affairs in the world of trade. When a section of the trade community gets out of joint or a stoppage occurs the effect is evinced in varying degrees in the other sections, and so in the telephone community all parts of the machine require to run smoothly, and the subscriber and his switchboard have their share in the work in order that the maximum efficiency may be attained.

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

BY F. ADDEY, B.SC., M.I.E.E., FELLOW I.R.E.

RECEIVING APPARATUS.

Crystal Detectors.

WE have now completed our brief preliminary survey of the field covered by modern wireless telegraphy and telephony, and can proceed to deal more fully with the various points which have been touched upon therein.

It will be convenient to vary the order adopted in the foregoing sketch, and to deal first with receiving apparatus.

It has been explained that the usual method employed to detect the oscillatory currents set up in the receiving aerial by spark signals is by cutting off from the telephones one half of each oscillation, and causing the other halves to blend together to produce a brief uni-directional current through the telephones. The process is called "rectification." The train of waves corresponding to each spark will thus produce a single pulse of current through the telephones, and cause a click to be heard. The successions of clicks so produced at the receiving end when long or short series of sparks occur at the sending station will be heard as long or short continuous sounds, and so the signals can be read.

Rectification is usually accomplished by making use of a property possessed by certain pairs of substances in contact with one another, by which a current of electricity is allowed to pass across the contact in one direction with comparative ease, but can only be sent across the contact in the opposite direction with considerable difficulty. To express the matter in technical language, the contact possesses "uni-lateral conductivity" (conductivity being the opposite of resistance, the property by which a substance opposes the flow of electricity), and as a consequence a greater driving pressure, or "electro-motive force," is required to send a current across the contact in one direction than in the other. It therefore follows that for electro-motive forces of *equal* magnitudes, applied across the contact first in one direction and then in the other, the currents which these electro-motive forces will produce will be unequal, the current in the direction in which the conductivity is good being much greater than that in the opposite direction. Since one or both of the substances used in these rectifying combinations are crystalline, the arrangements in which they are employed are known as "crystal detectors."

To investigate the electrical behaviour of any crystal detector, electro-motive forces of gradually increasing strength are applied across it in one direction, and the magnitude of the currents which are caused to flow by the various electro-motive forces are noted. The direction of the electro-motive forces is then reversed. They are increased in strength step by step as before, and again the currents corresponding to the various values of electro-motive force noted. The results are then plotted on a diagram, as in Fig. 9. Distances to the right or left of a vertical line represent to some scale the values of the electro-motive forces applied in one direction or the other, while distances measured upwards or downwards from a horizontal line represent the strengths and directions of the currents. Thus each observation of an electro-motive force and its corresponding current can be represented on the diagram by a dot placed in the proper position with reference to the two datum lines. The unit in which the electro-motive forces are expressed is the volt, while the currents, being very small, are expressed in milliamperes or even in microamperes. When the dots thus obtained by altering the electro-motive force by steps from some value in one direction through zero to some value in the opposite direction are joined by a continuous line a curve is obtained by means of which the strength of the current corresponding to any electro-motive force between the limits taken can be obtained. Such a curve is called the "characteristic curve" of the particular combination under investigation.

The combination most generally used now-a-days for a crystal detector consists of a small disc of polished steel, against which is pressed a crystal of carborundum. The characteristic curve

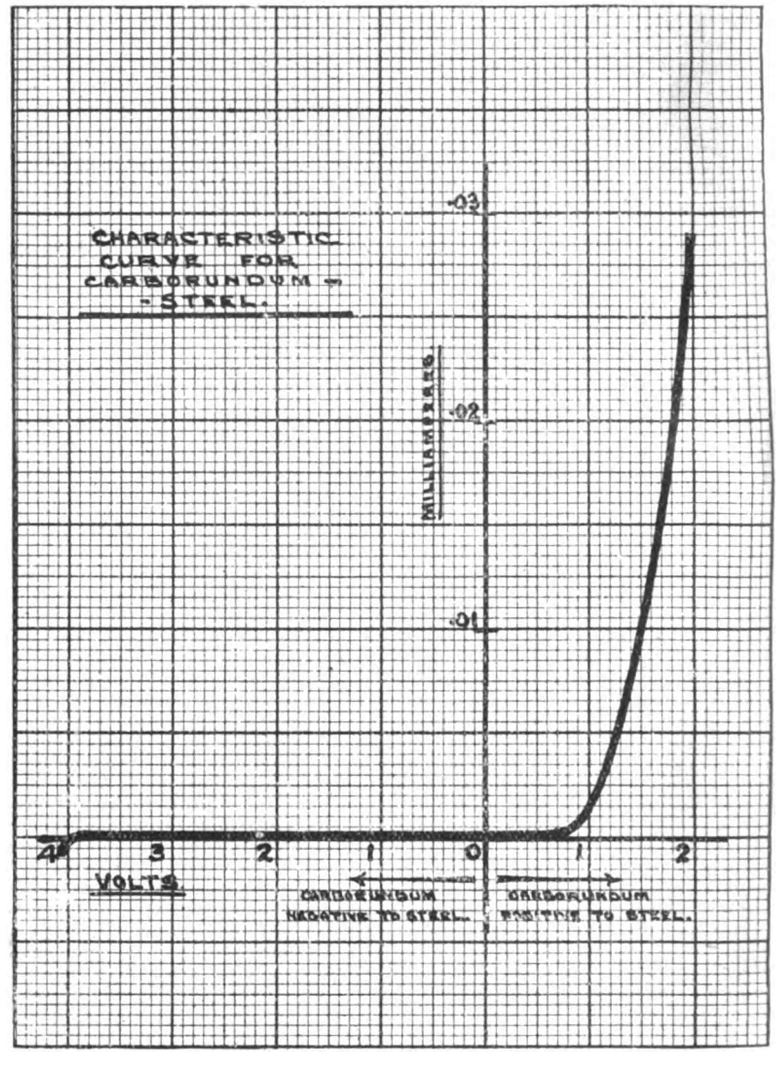


FIG. 9.—CHARACTERISTIC CURVE FOR CARBORUNDUM-STEEL COMBINATION

for such a combination is shown in Fig. 9. Suppose the electro-motive force to be applied across the contact in such a direction as to endeavour to send a current from the carborundum to the steel, that is, that the potential of the carborundum is made positive with regard to that of the steel. Then, as soon as the difference in potential between the corborundum and steel reaches 0.8 volts a current begins to flow, and increases in strength rapidly as the potential difference is made greater. If, however, the electro-motive force be applied in the reverse direction, the carborundum being made negative to the steel, no current will flow until the potential difference reaches nearly 4 volts. A potential difference of 1.5 volts with the carborundum positive to the steel will set up a

Digitized by Google

current of 0.01 milliamperes, while with an electro-motive force of the same amount in the reverse direction no current at all will pass. But although current can be sent across the contact from carborundum to steel so much more easily than in the reverse direction, the potential of the carborundum above that of the steel must be at least 0.8 volts, or no current will flow. This is a drawback to the simple carborundum-steel detector, as it means that this detector will only act as a rectifier when the amplitude of the alternating voltage applied to it exceeds a certain minimum amount, which, in the case of the detector to which the curve in Fig. 9 refers, is 0.8 volts. Below this amplitude of applied alternating voltage the detector acts as a block to currents in either direction.

It is, however, easy to overcome this difficulty. If a steady electro-motive force of 0.8 volts be applied from carborundum to steel we shall have the combination in the state represented by the point on the diagram at which the current curve is just beginning to rise. Suppose now we superimpose an alternating potential difference on this steady potential difference. When the pulse of the alternating voltage is in the same direction as the steady voltage the total potential of the carborundum above that of the steel will be increased, and, as the curve shows, a current will flow through the detector no matter how weak the applied alternating voltage may be. When the pulse of the alternating voltage is in the opposite direction, the total voltage applied to the detector is diminished or even reversed, and unless the amplitude of the alternating voltage be greater than about 4.8 volts no current will flow through the detector.

Thus the pulses of the alternating voltage in one direction will send current pulses through the detector, while the voltage pulses in the opposite direction will have no effect. An indicating instrument for direct currents joined in series with the detector will therefore be actuated by the rectified current set up when even a very weak alternating voltage is applied.

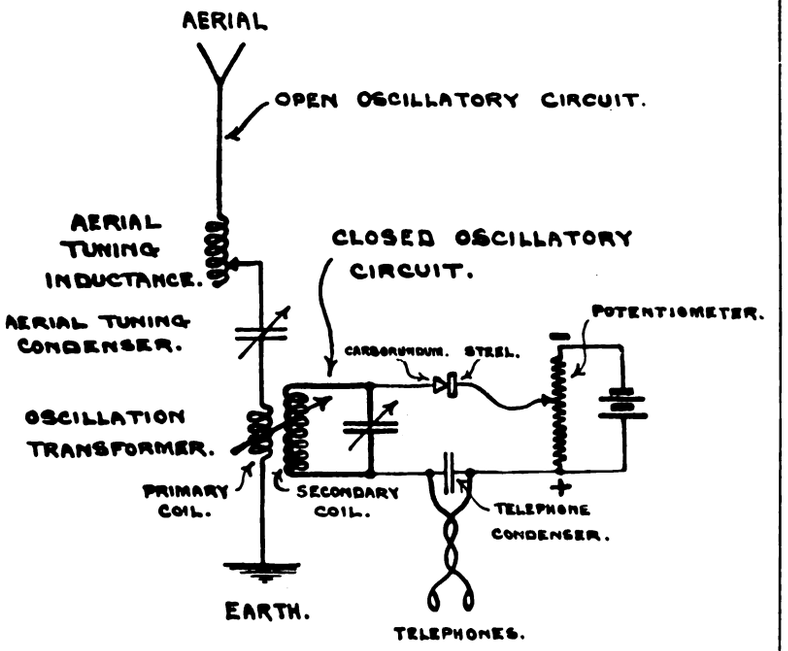

FIG. 10.—RECEIVING SET USING CRYSTAL DETECTOR.

Receiving Set.

The manner in which the crystal detector is used for the purpose of receiving wireless signals is shown in the diagram, Fig. 10. The open oscillatory circuit, consisting of aerial tuning inductance and aerial tuning condenser, has also included in it the primary coil of an oscillation transformer. This instrument consists of two coils placed near to one another so that oscillations in one coil, the primary, will induce oscillating impulses in the other coil, the secondary. This latter coil is joined in series with an adjustable condenser, so forming a closed oscillatory circuit. The arrows across the condensers in the diagram indicate that their capacities can be varied, and the arrow across the two coils of the oscillation transformer indicates that the "coupling" between these coils can be altered, that is, that the magnitude of the effect produced in the secondary coil by a given strength of alternating current in the primary coil can be varied. The open and closed oscillatory circuits are both adjusted so that their natural frequencies are the same as that of the incoming waves. This process is called "tuning" the circuits to the incoming waves. These waves will therefore set up oscillations in the open oscillatory circuit, and these oscillations will act on the closed oscillatory circuit by means of the coupling between the coils of the oscillation transformer and so the closed oscillatory circuit will also be set into oscillation. As the charges swing to and fro in the closed oscillatory circuit first one plate of the condenser and then the other plate will be charged positively, the opposite plate being, of course, charged negatively.

The crystal detector is joined across the plates of the condenser in series with the telephones, and consequently the alternating potential difference set up between the plates of the condenser will tend to set up currents through the detector and telephones, first in one direction and then in the other. By means of the potentiometer shown in the diagram a steady electro-motive force, which can be adjusted to any desired value within limits is applied to the detector. A "potentiometer" consists of a high resistance joined across the poles of a battery, and through which, therefore, a weak current is flowing. There is thus a fall of potential down the resistance, in the same way that there would be a fall of pressure along a narrow pipe through which water was being forced by a pump. The further along from the high pressure end of the pipe one went, the lower would the pressure be. Similarly, the further one goes along the resistance from the high potential end the lower is the potential. The high potential or positive end is joined to the carborundum through the telephones and the secondary of the oscillation transformer, while a wire joined to the steel can be moved along the resistance till a point is found at just the correct potential below that of the positive end to bring the detector into the state indicated by the upward bend of the curve in Fig. 9. The alternating electro-motive force across the plates of the condenser is superimposed on the steady electro-motive force from the potentiometer, and thus the total electro-motive force applied to the crystal contact will be alternately greater and less than that from the potentiometer alone. When the steady electro-motive force is adjusted to the proper value, a very small alternating voltage will cause a rectified current to flow through the detector and telephones, as explained above. Consequently, for each train of oscillations set up in the closed oscillatory circuit a series of unidirectional pulses will flow through the detector. These pulses are not sent directly through the telephones, but a condenser, known as the telephone condenser, which is joined up across the telephone leads, stores up the separate pulses, which are then discharged in a single longer pulse through the telephones, so producing a click. The various steps in the process are shown in diagrammatic form in Fig. 6.

It should be mentioned that with certain samples of carborundum the uni-lateral conductivity is in the reverse direction to that described above, current flowing more easily across the contact when the potential of the carborundum is lower than that of the steel. The principle of the action of the arrangement is however, unaltered.

Thermionic Valves.

The simple crystal detector, although still very widely used, is rapidly being superseded by detecting appliances in which use is made of the apparatus known as the "thermionic valve." These valves enable the sensitiveness of receiving apparatus to be much increased, and therefore the range over which communication can be carried on to be greatly extended. They have further important applications which will be explained later.

Digitized by Google

The thermionic valve is a remarkable example of the application to every-day purposes of phenomena which, when first discovered, appeared to be of no practical importance whatever. It consists of a small glass bulb, from which the air has been very fully exhausted. A filament, usually of tungsten, is placed inside, and has its ends brought out through the walls of the bulb. By joining the ends to a battery, a current can be sent through the filament and cause it to glow. The arrangement so far is simply a small electric lamp.

Opposite to the filament a metal plate is supported by suitable means. This plate is called the "anode" of the valve.

Between the anode and the filament is fixed a partition of wire gauze, known as the "grid" of the valve.

Both anode and grid are provided with wires led through the wall of the bulb. By means of these wires electrical contact can be established between the anode or the grid and external apparatus.

The relative positions of the different parts of a valve are shown in Fig. 11. There are several types of valve in use, and the actual arrangement in any particular case varies according to the type of valve considered. The principle, however, is the same in all.

If such a valve, having its filament made to glow by the current from a battery B_1 (Fig. 12), have another battery, B_2, known as the "high-tension" (H.T.) or "anode" battery joined up as shown, with its negative pole connected to the filament, and its positive pole joined to the anode, then it is found that a current, called the "anode current," will flow from the battery B_2, as indicated by the arrows, the circuit being completed through the apparently empty space inside the valve between the anode and the filament. This current can be measured by a suitable instrument A joined in the circuit. Why this current should flow across the gap between anode and filament will be explained later; for the present it may be taken for granted that such is the case.

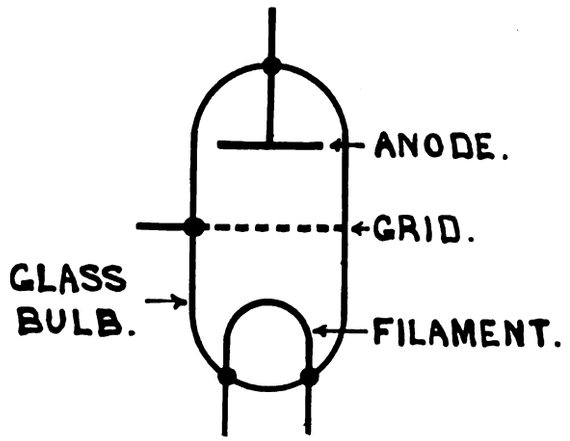

FIG. 11.—DIAGRAMS SHOWING ARRANGEMENT OF PARTS OF THERMIONIC VALVE.

It will be seen that, in its path from anode to filament, the anode current flows across the grid. It is found that the strength of the anode current depends not only on the electro-motive force of the battery B_2, as would naturally be expected, but also upon the difference of potential between the grid and the filament. By varying the potential of the grid the strength of the anode current can be altered, although the electro-motive force of the battery B_2 is kept constant.

It is from this fact that the name "valve" is derived. The apparatus acts like an electrical tap, the amount by which the tap is opened being governed by the potential of the grid.

The exact way in which the anode current depends on the potential of the grid can be ascertained by joining to the grid a potentiometer, consisting of a battery B_3 with a resistance across its terminals, as shown in Fig. 12. The centre point of the battery B_3 is joined to the negative end of the filament. The potential, or electrical pressure, at this point in the battery will, of course, be half-way between the potentials of the positive and the negative ends of the battery. The potential of the middle of the potentiometer resistance will also be half-way between the potentials of its ends, and will therefore be the same as that of the middle point of the battery.

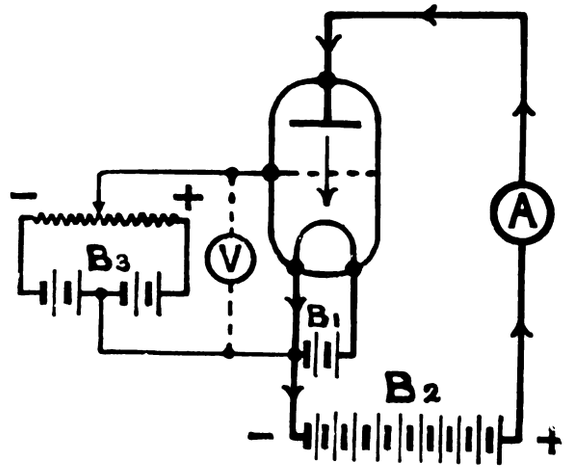

FIG. 12.—DETERMINATION OF ANODE CURRENT-GRID VOLTAGE CHARACTERISTIC OF VALVE.

Hence, when the potentiometer slider is in its middle position, the grid will be brought to the same potential as that of the negative end of the filament, while, by moving the slider to the right or left of the middle position, the grid potential can be made greater or less than that of the negative end of the filament.

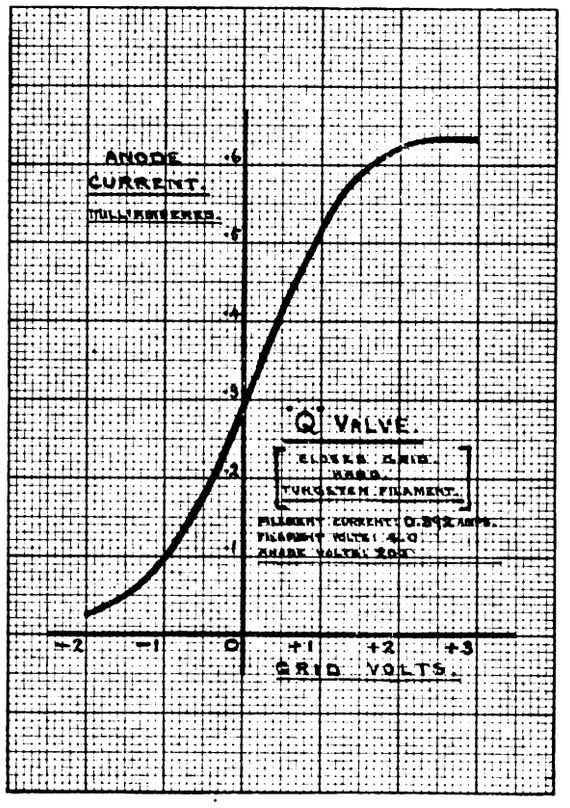

FIG. 13.—ANODE CURRENT-GRID VOLTS CHARACTERISTIC FOR "Q" VALVE

A voltmeter, V, joined between the grid and the negative end of the filament, enables the difference of potential to be ascertained.

Keeping the anode battery B_2 unchanged, we can now vary the grid potential from some negative value to some positive value with reference to the negative end of the filament, and for

Digitized by Google

each particular value of grid potential the corresponding value of the anode current can be noted. The results obtained can then be plotted on a diagram in the same way as has already been explained in connexion with the investigation of the action of crystal detectors, and the "characteristic curve" for the valve thus obtained. Such a curve is shown in Fig. 13. This curve should really be given its full title, "anode current—grid volts characteristic curve," as there are other characteristic curves which can be drawn to show the connection between the values of other pairs of quantities concerned in the action of a valve.

It should be noted that the connexion between grid potential and anode current shown by the curve only holds good for the conditions specified. If the electro-motive force of the battery B_2 be altered, or if the temperature of the filament be changed by varying the current from the battery B_1, the curve obtained will be different. For the particular conditions of filament temperature and anode battery voltage for which the curve was plotted, however, the anode current corresponding to any particular grid voltage can be at once obtained from the curve.

For understanding the manner in which a valve is used for the purposes of wireless telegraphy the fact that the anode current varies with the grid potential in the manner shown by the characteristic curve can be taken for granted. The results indicated by the characteristic curve, however, depend on the actions which take place inside the valve, and, as a matter of interest, a brief account of these will be given.

(*To be continued.*)

SELECT COMMITTEE ON TELEPHONE SERVICE, 1921.

RESUME OF EVIDENCE (*continued*).

On May 11, Mr. J. WALTER CLARK gave evidence on behalf of the National Chamber of Trade. He said that a questionnaire issued to members of that body resulted in a preponderance in favour of the message rate. They thought the proposed charges excessive, and wanted, if possible, to see a telephone in every house. He was of opinion that the rates for the provinces should be much cheaper than those for London.

Mr. R. A. DALZELL gave evidence on *May* 25 and 30. He amplified the Secretary's sketch of the Post Office organisation, and described the relationship of district managers to surveyors and postmasters. He dealt with the training of operators, their duties and loads, and the proportion of supervisors to operators, and in giving an explanation of wrong number troubles stated that on the magneto system subscribers failed to ring off in the case of nearly 16 per cent. of the calls made. On the 30th the Committee returned to the subject of the Executive Control of the Secretary, and Mr. Dalzell gave his opinion that the machine as now constituted was running very smoothly. He explained that the Post Office organisation was necessarily more complex than that of the National Telephone Company, and said that the establishment of a distinct organisation for telephones would be enormously more complicated and would increase expense. After defending the contention that working costs do not necessarily decrease with development, he explained the operating costs per message and why it was necessary to make a special charge for continuous service in certain small exchanges.

Mr. T. HOLME and Councillor OMBLER, representing the Hull Corporation, were called in and examined on *June* 6. They explained the Hull rates and admitted that a flat rate was better suited to a small system than a national one. They also endorsed the Post Office contention that an increase in the number of subscribers did not mean lower cost per subscriber. They described the organisation of the Hull telephone system. They had made a profit up to two or three years ago and were now raising their rates to meet the present loss.

Mr. FRANK BIRD gave evidence on *June* 8 on behalf of the Newspaper Society. He was strongly in favour of flat rates and claimed that newspapers did not overload their lines, which they had in excess of their actual requirements. He complained that the rentals of private wires were prohibitive. He thought that the Post Office was not run on business lines, and complained of over-supervision, but he admitted that he had never visited an exchange, and that his knowledge of business matters was confined to newspapers. He admitted, when pressed by the Chairman, that possibly his estimate of 10,000 calls as a reasonable load for a line too high, but thought that a load of 5,000 was low.

On June 13, Mr. G. L. HARDING, Surveyor for the South Wales District, was examined. He explained fully to the Committee the responsibility of surveyors with regard to the Telephone Service, and in what circumstances district managers referred to him, and in what cases they corresponded directly with headquarters, with the Accountant-General and with the Superintending Engineer. He stated the responsibility of postmasters with regard to staff, and gave a sketch of the general duties of the surveyor and his staff, their system of visiting districts, and the matters under their special control.

Mr. B. WAITE, District Manager of the Cardiff and Newport Districts followed, and informed the Committee of the duties of the contract manager, chief clerk and traffic superintendent who assisted him. He confirmed the opinion of the previous witness that the present system of control was the most economical, and said that for staff work to be performed in the district manager's office would necessitate two sets of staff. He explained the relations of the district manager with the postmasters, and described the former relation of district managers in the National Telephone Company with the provincial superintendents, who were telephone experts, and who were consulted on some of the matters on which surveyors were now consulted. Mr. Waite thought it would be desirable to have at the head of a district an administrative officer who controlled also the engineering department.

A FEMININE PLAINT TO THE EDITOR.

It seems you accuse us of slacking
Where buying the JOURNAL'S concerned,
In "Noblesse Oblige" we are lacking,
Its learned discourse we have spurned.

But, prithee, kind Sir, can you wonder?
The poor frivolous feminine mind
Is assuredly set poles asunder
From magnetos and all their dull kind.

The phrasing's pedantic and solemn,
The articles learned and slow,
Oh, will you not give us a column
On "Things that we'd *all* like to know?"

A cartoon to liven the pages,
Instead of a diagram sketch,
Some cryptic and witty adages,
A short story or two that will "fetch."

We promise you we'll buy the JOURNAL
If you'll give us a few Beauty Aids,
We'll all be subscribers eternal
For receipts to make jams—marmalades.

And, if all this prosiness quitting,
Our interest you would arouse
Then give us a pattern of knitting,
Or cami—ahem! or a blouse.

'Tis a masculine book and 'tis "stuffy."
To *us* it seems woefully dry,
Let it go! Be a little more "fluffy"
Please, Editor dear, won't you try?

DOROTHY TURNER.

Regent Exchange, June 10.

[Reflect, dear correspondent, what you ask
And judge if we be fitted for the task
To counsel beauty, in its hour of need
With toilet tips which may—or not—succeed.
Back to the cheek to call the vanished red
Or ebon tress to some fair moulting head!
Think if our scanty pages have the space
Or, if they had, whether they be the place
For those high matters, which, much better done
In *Home Bits* may be read by everyone?
Though operating curves we sometimes print
We can't give diagrams of . . . what you hint!
Nor can we draw, in tales replete with "grip"
Strong silent heroes with clean-shaven lip.
But seriously, we would bid you try
To read those papers which you deem so dry,
Much that looks dull of interest you'll find
If you approach it with enquiring mind.
Or, better still, O lady-readers, write!
Your views, your thoughts, your letters we invite
Which gladly we shall print, if they suggest
Some little telephonic interest.

EDITOR, "T. & T. J."]

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.1. The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. JULY, 1921. No. 76.

THE REVISED TARIFF AND REGISTRATION.

THE new tariff has brought into the limelight the question of call registration. Directly touching as it does the financial interests of the subscribers, this, the penultimate step in the operation of a call, has always been the central point of attack in public criticism of a message rate tariff. It is true that repeated investigations by representative bodies of business men have shown that the system of call recording followed at register exchanges is as accurate as any humanly operated system can be; but the very fact that in the last resort the human agent and not the machine controls the mechanism which registers a call makes it only natural that even the most reasonably minded subscribers should expect the administrative machinery to provide some safeguards against overcharge.

Such subscribers should find much to allay their anxiety in the recently issued London Traffic Instruction on call supervision in relation to accuracy of registration, the principal points of which have been embodied in a printed leaflet distributed to every London telephonist. The central idea of the instruction is to give expression to the subscribers' point of view; for, so far as the routine of operating is concerned, the new tariff does not introduce any change either in the incidence or frequency of the registration step: under the old tariff the register key was depressed in the case of flat rate and message rate calls alike. The new tariff, however, makes this difference:—under the old conditions, though nearly 80 per cent. of the London subscribers were message rate subscribers, less than 50 per cent. of the traffic was message rate traffic; with the result that in more than 50 per cent. of the calls handled the charge made to the subscriber did not depend in any way upon the telephonist's accuracy of recording. Now it depends wholly upon this.

"Use to the full the comprehensive machinery of call supervision provided by modern switchboards and give the subscriber the benefit of any doubt," is the new instruction in a nutshell. This is an earnest of the spirit in which the new tariff will be applied. At first sight it may seem an exaggeration to say that the success of the new rates—in its complete sense—depends upon the degree of efficiency attained in the simplest of the chain of operations that go to make up an effective call; but there is a very real sense in which the statement may fairly be made. For the complicated mechanism of co-operative effort called "Telephone Service," goodwill is the only lubricant: and of all the multifarious service troubles inherent even in the most perfect telephone service none have deeper adverse re-action on the co-operative possibilities of the subscriber than charge disputes. In a sense widely different from the obvious, therefore, the key to the success of the new tariff is the register key.

THE TELEGRAPH PROBLEM.

WE all have our solutions of the Telegraph Problem. Mr. Skinner, in this issue, tells us the way in which he thinks the deficit can be removed, and he will not think us disrespectful if we suggest that his solution is not altogether novel. The daily press has insisted that if only the product is sufficiently cheapened there is no limit to the profits which could be made. Those newspapers which once were a halfpenny and are now a penny are the most eloquent on the subject, and their reluctance to reduce their price to a halfpenny again is ascribable to a laudable spirit of self-sacrifice. It is very luring to say that if the price of telegrams were only reduced to sixpence we should have thousands more telegrams and all our troubles would be ended. The arithmetic of the subject is not encouraging. If we take the total cost of the staff and divide it by the total number of telegrams we shall get a figure which sets one thinking. Moreover, it is not at all certain that even if such a tariff could be proved to be remunerative the public at the present moment wants a cheaper rate, either deferred, or posted, or treated in any other inferior way. In a vast country like the United States there are possibilities for graded tariffs over long distances which do not arise in the United Kingdom. Nor at a time of industrial depression is it at all opportune to make such a venture. There is a limited demand, at the moment, for most commodities, and it is the business telegram which happens to be lacking just at present. Not even the wildest enthusiast for a deferred tariff will expect to find his thousands of supporters in the business communities.

All this sounds very hopeless, but it is only facing facts, after all. A nationalised service does cater for the country at large in a way which is not possible to a privately-owned service. It is rather remarkable to reflect that we are trying to serve even the smallest town with the same quality of service as the larger town. There is in America a device known as the "Way" circuit. It is a long omnibus circuit serving in some cases as many as thirty small towns. Possibly it gives them some sort of a telegraph service; at any rate, when two of the offices are working together nothing happens to the other twenty-eight. That may or may not be the

Digitized by Google

true ideal. It may be the case that where there is little traffic it is sound economic theory to cheapen the service. At any rate the nationalised services have not done this. They have not graded the service in quality according to the amount of support which they get from the particular neighbourhood. To give a service of practically identical quality to every office is a high ideal, but it is a costly ideal. It involves unoccupied time somewhere of plant and of staff. It may be well worth it for the sake of the cohesion of the nation and the rapidity of interchange of communication, just as a branch railway line has its special value. But the network of telegraphs includes a great deal of branch lines. They are everywhere. No village of any considerable size can get away from them. And while students of transport have been suggesting very limited facilities on branch lines, we in the telegraph service—allegorically speaking—give them expresses and dining-cars.

This is not to say that we should be complacent. On the contrary, there is room for study. Output is an old question and yet if the staff charge per telegram is to be reduced we shall all have to co-operate to increase the output. None of us likes the thought that our industry is labelled unsuccessful, whatever explanations we may be able to give. Sooner or later we shall have to face this issue. Not until we have brought the staff charge per telegram within more reasonable proportions of the total charge to the public will it be possible to consider the various schemes which contributors ask us to publish. There may then be opportunities for developments in the way of finer grading of services, but before that day comes we have to face the bigger problem. No one who knows the telegraph service will accuse its officers of lack of zeal, or enterprise, or keenness. The contributions to which we have referred, such as Mr. Skinner's, bear tribute to these qualities. But if we are to use the newer types of telegraphy to good purpose, to the furthering of the usefulness of our craft to the public, we must set to work to find out in what way we can so economise the details of labour as to encourage the productivity.

A FEMININE PLAINT.

SOME sprightly verses from a correspondent in one of the London Telephone exchanges which we print in another column re-open a vexed and difficult question, and we are glad to give them publicity and, as far as we are able, to take up the gauntlet thrown down. We are, of course, eager that the JOURNAL should circulate in every exchange and that it should contain matters of interest to every telephonist—but we think that interest should revolve round the varied and manifold aspects of the Service and the personal and practical problems connected with it. It is a very wide field, and affords scope for matter which cannot be styled technical or dry. We feel sure that the majority of telephonists agree with us in this view and will understand that the inclusion of a special ladies' column in the JOURNAL would not be a satisfactory remedy of any alleged lack of interest. Purely feminine questions of dress and household management are dealt with so fully in dozens of ladies' papers, not to mention the considerable space devoted to them in the daily and Sunday press, one or several of which every telephonist doubtless reads, that it would be a work of supererogation to occupy our scanty space in an effort to rival those expert purveyors of feminine fare. We have our lighter side, but, after all, ours is a telegraph and telephone journal, and comic sketches, puzzles, anagrams, and serial stories would be out of place in it unless they had some bearing on our work.

We have from time to time dealt with operating problems and with traffic questions generally, and we are always glad to publish articles, paragraphs and pictures dealing with the social life and sports of the exchange staffs. If we do not provide more matter of close interest to telephonists, we think the remedy is largely in their own hands. We should be glad to hear from them more frequently, and will undertake to give a sympathetic hearing to their views. There must be vexed questions and two-sided problems on which they have opinions. We have before stated that the JOURNAL exists for the interchange and expression of opinion, and its success must necessarily be founded on co-operation. All communications sent to us are treated in confidence, and if they contain anything of a helpful, interesting, or amusing nature they will be welcomed by the Committee. We hope we shall not be blamed for quoting an old truism, if we point out that a subject which one tries to understand at once becomes interesting; and this applies especially to our work. We know from pleasant experience what a keen interest many telephonists take in problems bearing on the Service and we beg those who think the subject dry to give it a short trial.

HIC ET UBIQUE.

WE confess we were very pleased to read in the Press a circumstantial and uncompromising rejoinder by the Postmaster-General to Mr. Macquisten's legend of Dalkeith. Amongst other things the legend told of prodigality of staff employed on what in his wisdom our critic considered a simple job. This kind of legend has been very rife of late, and the number of superfluous staff employed on the "simple job" is always an increasing number. We expect the next telephone critic who discovers three or four men installing a telephone will take, like Falstaff, the points of eleven rogues in buckram on his target.

NOVALIS says somewhere: "There is an ideal series of events which run parallel with the real ones. They rarely coincide." We might also say that there is a comic series of events running parallel with real ones; which also rarely coincide. There are people who live in a comic world, who demand that their papers, even their daily ones, be comic papers and their public men comedians; and we know that where there is a demand there is usually a supply. To such the comic aspect of life is so normal that its incongruities remain unnoticed. Fact and fiction are inextricably confused in their minds, and they find the latter infinitely the more amusing.

WE have received the following cuttings from a thoroughly unreliable source:—

Evening Times, Feb. 29.

Mr. Samuel Slumkey (Eatanswill, North) asked the Postmaster-General if it was the fact that 75 officers of the post office telephone department were employed in taking down a telephone pole in the forest of Sapsworth.

The Postmaster-General in reply stated that the pole, which was a heavy one, was removed by 3 men and a foreman. The figure of 75 referred to by the Hon. Member appeared to include a chief ranger, 2 parkkeepers, and 68 Loyal Sons of Temperance, who were picnicing in the forest, and 1 errand boy, all of whom were displaying great interest in the work.

From the same, June 31.

Horatio Fizkin (Eatanswill, South) asked the Postmaster-General whether he was aware that 957 servants of the post office were engaged in

Digitized by Google

removing a telephone bracket from the High Street, Eatanswill, and whether in the days of the National Telephone Company 2 employees would not have sufficed for the job.

The Postmaster-General in reply said the work had been satisfactorily carried out by 2 members of the post office engineering staff. Careful enquiry seemed to indicate that 614 officers and men of the Suffolk Light Infantry, 327 members of a procession of unemployed (who were passing while the removal was being effected), 7 policemen, 1 steeple-jack, 1 turn-cock, 3 brush-binders, and 2 organ-grinders must have been included in the Hon. Member's total of 957.

THE following remarks from the *West London Observer* will both amuse and instruct our readers: "The G.P.O. Telephone Mechanical Staff is having a busy time—cutting off the 'phones, hence the profusion of little canvas huts to be found on the pavement and elsewhere. This is the result of the great telephone swindle."

So that's how they think it's done—cut off at the main like water!

THE BAUDOT.—XXII.

BY J. J. T.

THIS same axle A^1 also carries a geared wheel which when the receiver is placed in position on the base-plate engages with a slower running wheel *inside* the receiver connected to the printing-axle. In the weight driven form of receiver the necessary train-work is also geared on to the moderator axle so that when the receiver is placed in position the engagement of the moderator axle with the printing-axle revolves the latter and its printing mechanism.

In the case of the modern electric motor-driven type of receiver the motor is placed at the side of the receiver (Fig. XIII, Vol. VI, No. 57) and drives the printing-axle by means of an endless band and a grooved wooden driving wheel fixed on to a short extension of the printing-axle *outside* the receiver and behind the rear casing plate. When, in this case, the receiver is placed on the base plate it is therefore the printing-axle which drives the moderator axle. In both cases it is the moderator which determines the running speed of the receiver.

The electro-magnet brake coils have an ohmic resistance of 40 per coil. The free end of each of these terminates on the ebonite block R (Fig. LX) which is also provided with terminals *h h* from which the end of the coils are led away. An armature BB (Figs. LVIII, LX, LXI) the lower part of which is hinged under the base plate at M (Fig. LXI) carries a curved flat spring S^1S^1 with an adjusting screw M^1 (Figs. LX, LXI) which latter determines the position of a cork brake P (Fig. LXI) in relation to the periphery of the brake wheel BW. A capstan-headed screw LS (Figs. LX, LXI) limits the distance of the armature BB from the cores of the coils EM. BB is provided with diamagnetic facings to prevent the "sticking" of the armature and pole-pieces while the springs S^1S^1 further assist to throw off the armature once a current has ceased to flow in the coils. When the brake current from Rings 6 to 3 passes through the coils EM it attracts the armature BB. This action brings the cork brake P (Fig. LXI) up against the periphery of BW gently damping down the speed, for as already stated the running speed of a receiver is fixed slightly higher than that of the distributor of the installation to which it belongs, and this advance speed is determined by the *moderator* which we shall presently examine. The British method of adjustment is such that the moderator speed is fixed at a figure just so much in advance of the distributor that a gentle action of the cork brake on BW at *every* revolution of the distributor suffices to reduce the *running* speed of the *receiver* to the actual speed of the *distributor*, or at least within practical and workable limits. It will be seen from this statement that the moderator need not be so finely adjusted a piece of mechanism as that demanded by the more delicate functions of the distributor governor. The *moderator* is in fact a comparatively roughly constructed type of speed governor.

Before proceeding to the closer examination of the moderator it will be appropriate to mention that although the damping down of the receiver speed by the action of the brake current is a very simple method of phasing the receiver with its distributor it is nevertheless an operation which should only take effect at a certain moment during the cycle of movement of the receiver mechanism. We must therefore return to our study of the Baudot receiver selectors and their action (Art. XV). It will then be realised that it is impossible to actuate the selector levers *during* the passage of the selector N and its cams KK^1 (Fig. XL) into the arc occupied by these same levers. As a matter of fact it is absolutely necessary that these levers which are about to be displaced to the combination selected may be actuated before KK^1 reaches appendix (or selector) lever No. 1. We shall therefore be in the ideal position if the levers are actuated when the double selecting cam KK^1 *is as far away as possible from the appendix levers' field of action.* This may be crystallised into a rule which lays down the adjustment that when the third appendix is actuated the middle of the selecting cam should be diametrically opposite to this third appendix; *i.e.*, when the third appendix is actuated that portion of the combiner wheel to which the selecting cam is fixed should

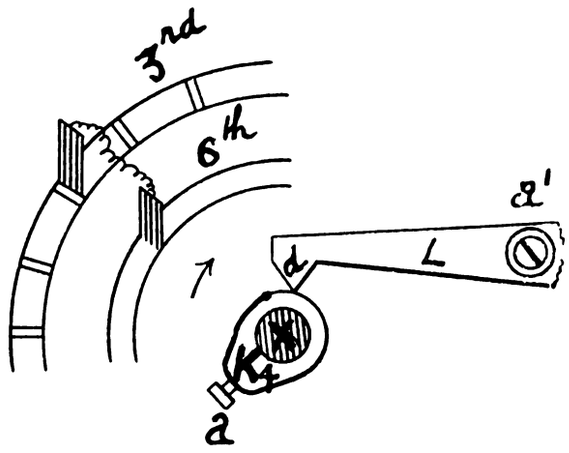

FIG. LXII.

be in its nearest possible position to the base plate. But the receiver is arranged to revolve faster than its distributor and it must therefore happen, and that very frequently, that the correct relationship will not be maintained, and that even the braking effect must take place at such a moment as to maintain this correct relationship. With this end in view the segments of Ring III chosen to actuate the electro-magnetic brake coils are so chosen that the passage of the brake-brush over these segments practically coincides with the segment joined to the third electro-magnet of the respective receivers of the installation. Now the selecting cam KK^1 (Fig. XL) is, as we know, a fixture upon the combiner wheel C, and to maintain the relationship just mentioned between this cam and the actuation of the third appendix *during reception* it is necessary that as KK^1 are not adjustable some other means must be found to accomplish complete phasing. This is done by means of the circuit-closing cam K^4 (Fig. LXII). In the case of this diagram to obtain correct adjustment K^4 should be shifted round upon the axle *x* (by first loosening the binding screw *a*) until it is in such a position that the cam just begins to raise the balance lever L at *d* and thus commences to complete the brake circuit when the selecting cam KK^1 (Fig. XL) is in a diametrically opposite position to the third appendix. There it should be fixed and as the brake brushes have already been adjusted in the relationship mentioned above the braking effect of the energised coils EM (Figs. LX, LX1) can only occur at the correct moment, that is when the selecting cam is well out of all possible action.

(*To be continued.*)

SLUMPS—AND VISIONS.

By J. SKINNER (Brighton).

THE general decrease of business everywhere is beginning to make even those usually thoughtless and indifferent pause and reflect. In Post Office circles the fall in telegraph traffic is apparent to all, and is doubtless causing much anxiety to those responsible for the administration. It is not our purpose to discuss the various causes that have contributed to this unfortunate state of affairs, but the fact remains that we are face to face with a decided "slump."

Notwithstanding the difficulties in which the country has been plunged, and the many unsolved national and international problems following the great war, the Press has seen fit to deliver a bitter attack upon the Telephone Service. Only a strong respect for the official regulations has prevented many of us from taking up the cudgels on behalf of the libelled service, and at least refuting a few of the prevarications circulated daily. In passing, I may perhaps be permitted to remark that the general tone of the Press to-day seems to indicate that we have not made much progress upward from the savage state. The newspaper proprietors, with a very few notable exceptions, probably serve up what they think their readers desire.

Our chivalrous gentlemen of the Press readily and conveniently forget the debt they owe to the Telegraph and Telephone Services, and, "on receipt of instructions," placed the Telephone Hymn of Hate record on the gramaphone, and let it go fortissimo. Well might Shakespeare exclaim :—

"Freeze, freeze thou bitter sky,
Thou does not bite so nigh
As benefits forgot."

Artemus Ward seems to have been well acquainted with the Press, for he once wrote :—

> "Sum editers in a sertain town which shall be nameless air both sneakin and ornery. They cum in krowds to my Show and then axt me ten sents a line for Puffs. I objectid to payin, but they sed ef I didn't down with the dust thay'd wipe my Show from the face of the earth."

This, gentle reader, is by the way.

NOT UNPRECEDENTED.

The "slump" in trade is not, however, without precedent. During the years immediately following the Napoleonic wars, history tells us business matters were indeed serious in Europe, and that prices were "famine high." One writer says :—"The triumph of the nation was succeeded by a reaction of internal distress and discontent. Trade languished from the exhaustion of the Continental nations, and their consequent inability to purchase our goods. A multitude of persons were thrown out of employment through the depressed state of trade, and their numbers were swelled by the soldiers and sailors discharged at the termination of the war. Thus seditions and tumults arose. . . . " Verily, history indeed repeats itself !

Many readers will remember that the South African War—now regarded as quite a minor campaign—which added 160 millions to our National Debt amongst other inconveniences—caused considerable disturbance to business. Figures published by the Board of Trade show that, whereas the percentage of unemployed stood at 2.40 in 1899 (the year of the outbreak of war) in 1904, two years after peace had been signed, the percentage had risen to 6.80. In 1911, however, the figures had fallen to 3.0. How trivial these records seem, when compared with the appalling figures of to-day !

THE ABIDING TELEGRAM.

The Telegraph Service, the Cinderella of the family, is feeling the depression keenly. It has indeed borne its full share of "the slings and arrows of outrageous fortune" during its career, and has had to remain content with the drudgery of the kitchen, whilst its more fortunate sister, the Telephone Service, expensively dressed, has sat in the drawing-room, to receive homage of countless admirers and wreathes of roses—with other offerings—from the Press.

Nevertheless, the telegram will always remain with us. It is the poor man's Mercury, the business man's "stand-by," the wealthy man's toy, and the general public's friend in every emergency. The great majority of people in this country will never be able to afford the luxury of a telephone, and will continue to rely upon the Telegraph Service as need arises.

Someone once said that the Telegraph Service was past praying for, but enthusiasts in the profession—and there are many of them—do not agree. They ask why not "boost" the service ? Only Post Office officials read the Post Office Guide, and members of the public generally are unaware of the facilities afforded by way of the telegraph. Why not large type notices in every Post Office advertising the half-rate and week-end cable rates ? Something pronounced and arresting ; there might even be a picture of the prodigal son, in a remote colony, receiving a deferred rate message from home ! Why not a constant reminder, in bold letters, that a telegram can be sent to ANY place in the British Isles for one shilling ? Why not a special cheap rate—one shilling for 40 or 50 words—for messages to be delivered by post the following morning ? In short, why not advertise "the goods" and increase the facilities ? Then think of the advertising space wasted in regard to telegram forms. What revenue would accrue if only the backs of the forms were used to advertise household remedies and what not. Just fancy—but no, we had better not !

IN FUTURO.

When one thinks of the possbilities of the future, the gloom of the present is dispelled. The telephone is yet in its infancy, whilst the telegraph has only just begun to walk.

Our colleagues in the Telephone Service will continue to press forward, *per angusta ad augusta*. Doubtless many of them have already seen the vision, but perhaps we may be permitted to adumbrate a few of the developments that may follow. Amongst the many items that come to mind we might suggest that an educative and recreative bureau could be established in the central exchange at each large town, so that subscribers could receive information and instruction at a moment's notice. Students of foreign languages could have portions of standard works read to them, in the desired language (per phonograph-telephone if aliens remain *verboten*).

Business men could, at once, obtain information on almost any subject. Invalids could have selections of music played to them, almost *ad infinitum* (if they could stand it) with the assistance of the phonograph, and the latest news could be read to subscribers throughout the day.

The generally admired dulcet tones of our fair telephonists would be of decided therapeutic value in convalescence, and one is confident that the medical profession would order the installation of the telephone in many cases where the patients were of the male sex !

Long distance telephony will be one of the features of the future, and the development of the thermionic valve will permit of conversations over vast distances. The prodigal son referred to above may even be able to telephone home, if he has "struck" a gold or coal mine !

Machine telegraphy is making such palpable strides that it needs no advertisement here. Perhaps the day is not far ahead when the sender of a telegram will go into a "call box" and actually transmit his telegram by means of a type-writer keyboard.

EXTENSIONS.

Many readers will doubtless recollect a most interesting article written a few years ago by Mr. John Lee, M.A., on the "Red Milkman," in which, we think, it was suggested that the postman should deliver the milk. Since that day many, many additional duties have been thrust upon the Post Office, but have we reached the limit of that great institution's usefulness ? The writer humbly suggests No ! far from it.

After acquiring the country's milk trade, the pawnbroking business should be taken over. Here is an El Dorado indeed, and future Postmasters-General would be able to announce phenomenal profits. Perhaps even "The Trade" might be absorbed, and instead of half-a-dozen public-houses in one street, we could have the business confined to the head and branch offices, under strict State supervision ! Objectors to this development are reminded that there would be considerable profits, and after all, did not a celebrated Roman emperor once remark, when a question arose regarding the source of certain revenue," "Non Alet !" For the benefit of our readers who have forgotten their Roman history it should perhaps be stated that fragrant paper money was not in use during this emperor's reign.

The Post Offices of the future should, and will be, housed in stately and handsome buildings. When the writer was in Durban, he enquired for the Post Office, and was directed to a palatial edifice boasting a lofty tower with a peal of bells. He had to go inside to receive assurance that it really was a Post Office before he would believe it. And when he arrived inside and beheld the marble, brass and mahogany—many cathedrals would be glad of such fittings—he was speechless with joy ! The doorkeeper in such a building must be even a prouder man than a commissionaire at a picture palace.

The head Post Offices should be arranged on the lines of the big department stores, and each one should include a restaurant. Adequate seating accommodation would be a feature, and good circulating libraries at cheap rates might be installed. Provision should be made for minding the babies, whilst the mothers are transacting business and taking refreshment. A selected postman, experienced in such matters, could be available for this duty. This is not so ridiculous as it sounds, for at one of the great 125th Street Stores in New York an Englishman is employed to mind the babies outside. He gives a receipt for each child to its fond mother, and is evidently successful, for he is described as an expert tear drier and rattle retriever. What is possible in New York can surely be done in England, and here is a fine opportunity for the Post Office.

Matters are moving elsewhere, for a writer in the London *Daily News* mentioned recently that in Switzerland one could pay taxes, doctors' bills and a dozen or more accounts at the Post Office there, and that the Post Office is the ordinary channel for the distribution of newspapers.

We have wandered from our main theme somewhat, but after all, the Telegraph and Telephone Services are living members of that great body, the Post Office, and the welfare of that body depends upon the sound health of each and every organ contained in it.

To those amongst us feeling somewhat depressed at the outlook we would say "Take courage," and remind them of the philosopher who once said :—"My worst troubles were those that never happened." The clouds will pass, and we shall then march forward to such achievements as Rowland Hill Morse and Bell never even dreamed of.

One envies our youthful colleagues, for they will reap the harvest—the wonderful harvest resulting from hard spade work on the part of those bearing the heat and burden of to-day. "Carry on !"

Digitized by Google

TELEGRAPHIC MEMORABILIA.

IF my information be correct there appears to be a tendency across the Atlantic to veer round towards tape-printing as against page-printing in connexion with machine telegraphy. It is possibly that despite the beauty and perfection of the Murray and Western Electric systems, for example, the extra mechanism and line-time involved in obtaining the page-printed telegram, users of to-day have by no means proved so keen in its advocacy, faced as they are and as must needs be the case with post-war economic conditions.

During the past few weeks amongst those who have visited the C.T.O., London, are Mr. Gates of Manchester, *en route* for Paris on a semi-official visit to that city; Monsieur and Madame Semeelen (*nee* Mowatt), the former to obtain a closer view and experience of Baudot Triple Duplex in his capacity as Technical Officer of the Antwerp office, Mr. John Munro (late of T.S. Foreign), Principal Inspector of the Egyptian State Telegraphs, Cairo, home on short furlough and looking the picture of health, and Mr. Sun, of the Chinese State Telegraphs, who is spending a week or two with us studying the British telegraph system and organisation, also the much-esteemed Mr. H. A. Harrison, fresh from a visit to Chicago, still keenly interested in machine telegraphy and brimful of information regarding the use to which this type of our craft is utilised in the States. "Over yonder" it appears that some of the larger corporations have their own telegraph offices and their own lines stretching "up town," "down town," and to country depots. In Chicago one of these companies possesses a central office with an instrument room to accommodate from one hundred to one hundred and fifty operators, for the exclusive use of the business of the firm. Telephonic communications one may be quite sure are not excluded from the organisation, but it may prove an eye-opener to certain of our readers to learn how wide-awake it is possible for telegraphy to be in modern business methods, while it is equally heartening to those who have believed in the vitality of the telegraphic art to learn that telegraphy can live and thrive in friendly rivalry with the telephone. All the apparatus in the above office, it is understood, was on the type-printing principle.

Mr. Harrison was loud in praise of the Western Union Company's Central Telegraph Office in the same city. Its appointments were apparently on a magnificent scale. Even the retiring rooms and bathrooms of the messengers, I repeat "bathrooms of the *messengers*" were equal to that of some of the best hotels of the city. Should a messenger's uniform appear a little less smart than usual all the owner has to do is to hand it in to the Renovating Department in the evening when he leaves duty to find it cleaned and pressed ready for use in the morning when its owner again signs on. European administrations, please copy!

All Post Office readers will be pleased to note that Sir Andrew M. Ogilvie was recently elected an Associate of the Institute of Electrical Engineers.

It is gratifying to record that at long last the Institute has now returned to its home on the Victoria Embankment and the autumn should find its activities in full swing. The re-opening was practically inaugurated by a unique day in the history of the Institution when two Danish engineers, Johnsen and Rahbek, aided by Mr. Frank Gill, explained the new phenomenon in connexion with electro-static attraction which the two former had discovered in 1917, and had applied to telegraphy and telephony. It is stated that as applied to telegraphy an excellent radio recorder is obtainable, currents from even small valves being sufficient to record speeds of several hundred words per minute.

During this same inaugural period the Council of the Institute extended true British hospitality to a party of the chief engineers of Holland who were paying a return visit to this country to inspect electrical and other kindred organisations.

The British Post Office has been rather proud of itself in the realms of sport this summer. It is not, however, likely that it will be able to readily beat the record established by Mr. W. J. Hunter, of the Deal Post Office, who won the Amateur Golf Championship, or that of the score of 84 made by Mr. W. T. Cook of the C.T.O. in his maiden first class match on behalf of Surrey.

The working of the direct wire which has recently been established between the Paris Bourse Office and London Stock Exchange has proved a complete success, and has perhaps given more satisfaction to the City than anything the C.T.O. has accomplished for a long time. Up to the time of writing only a simplex Hughes has been employed, but there are signs that more traffic channels will soon be needed. It has apparently surprised some folk that the output of this "old-fashioned" apparatus should have been capable of so high an output as 70 to 80 telegrams per hour in skilful hands. One has heard prophesies of its being scrapped, and yet it survives and insists upon surviving. The seasonal wire between London and St. Malo established for the potato traffic is worked by this same apparatus and easily deals with 70 per hour. The new Anglo-German communication between London and Dresden, opened on May 21, is worked by means of Hughes, and the historic opening of the direct line between London and Prag on the 27th of the same month was inaugurated by the same system and for the present is so working. This latter circuit, be it remembered, is the first direct Anglo-Czecho-Slovakian line established and thus marks the calendar.

While dilating upon the undoubted virtues of Hughes apparatus, one must hold the balance fairly and place on record the fact that at the time of writing the Booth-Wilmott keyboard has been working for about two weeks with but little more than the barest maintenance attention, and bids fair to have come to stay when certain elemental changes have been made.

Even if one were inclined to forget the place which high-speed printing telegraphy is bound to take in the world there comes a happy little souvenir post-card from Athens from that modest Baudot expert, Monsieur P. Mércy, of Paris, who is occupied in installating the above system on behalf of the Greek Government.

Electricity with its usual enterprise is publishing in its weekly issue Sir William Noble's paper which was read before the I.E.E. on "The Long Distance Telephone System of the United Kingdom." In effect this paper is really a history and a complete one of that of Trunk Telephone development in these islands, and should prove a classic on the subject of telephones.

According to *Reuter*—

> French wireless experts state that as the result of experiments direct wireless communication between Paris and New York can now be obtained. This will reduce the time of transmission by two hours, as hitherto communications have had to be sent *via* Lyons or the big station near Bordeaux.

One of our watchful correspondents writes, referring to the attempted "Conquest of Mount Everest," on behalf of the Royal Geographical Society and the Alpine Club and the fact that news of the progress of the expedition will be sent by native runners, that it is a wonder that portable wireless is not to be used for this very special occasion.

The Direct Spanish Telegraph Company's accounts for 1920 show that a dividend of 10 per cent. was paid on the Ordinary Shares (free of tax), and that, after paying Income Tax and E.P.D. for 1919, there was still a credit balance of over £46,000. The Great Northern Telegraph Company's Directors announce the distribution of a total dividend and bonus of 24 per cent., carrying forward the formidable sum of £285,892.

Sir William Slingo's arrival in Peru as Controller-General of Peruvian Posts, Telegraphs and Wireless Communications under the concession granted to a private company, leads one to query whether after all the British home-grown Civil servant is so unprogressive an individual after all. Evidently a business organisation not generally accredited with undue sentiment has found the employment of an ex-Government official a profitable investment even in his seventh decade.

On May 31 Mr. C. F. Moody, Assistant Superintendent, late Class II, retired from the Telegraph Service, having completed his sixtieth year. No ordinary eulogy would fit the occasion. Words themselves in all their varying terms of deepest affection and of highest esteem would miserably fail to express what was a unique relationship between supervised and supervisor in the case of "Fred." Around the personality of the man there was an atmosphere of kindliness which forbade the harsh word, the unkind thought, or the ungracious retort, while the honest fun that twinkled out from this atmosphere served only to breathe out yet more of a real love for mankind. "Dear old Fred" said the lads and lassies as he left us, and "Dear old Fred," perhaps best expresses the sum total of the lasting impression of C.F.M. which will ever remain with us. Those who knew him best will best realise that the pen that wrote the above has but partly succeeded to do honour to a very lovable character.

Friends of Mr. George Scholey, pensioned overseer, who had rendered admirable service during and subsequent to the war by his assistance in the Cable Room, C.T.O., will hear with keen regret of his demise on May 20 after a brief illness. As a telegraphist he had spent some part of his early service with the Direct Spanish Company, transferring to the late Submarine Telegraph Company somewhere in the early eighties, and continuing his service under the aegis of the Government when the latter company passed from private control.

The City and Guilds Report for 1920 shows that in 1920 there were the following increases in the number of students who sat for—

	1920.	1919.
Telegraphy	579	198
Telephony	683	267
Magnetism and Electricity ...	839	268

As a leading electrical journal remarks, "this increase is doubtless to be attributed to the return of Post Office employees to their ordinary civil duties."

According to *The Times* the price paid by the British Government to the Direct United States Cable Company for the "cables and properties" of the latter company was £70,086 in cash and £506,700 in 5 per cent. National War Bonds 1923.

It is hoped that the Eastern Telegraph Company's system to India and the Far East will shortly be sufficiently renewed and improved as to increase the carrying capacity of its submarine cables. Work, it is understood, is actually going on in connexion with the Company's Red Sea cables at the present time.

Digitized by Google

The following somewhat cryptic advertisement appeared in the London *Times* of June 6:—

> WANTED, a firm or gentleman of influence to take the responsibility and immediate charge of the exploitation of a TELEGRAPH APPARATUS (covered by five patents and just completed) which so reduces and expedites the work of despatch and delivery that all telegraph services will be enabled to make a substantial reduction in their rates and at the same time considerably increase their profits—an epoch-making development which also benefits the telephone service and would seem to have come at the psychological moment to help the Postmaster-General out of his present financial difficulties. Terms of Agreement with the applicant need not necessarily interfere with his own business.—Address, &c., &c.

The gathering of retired officers of the C.T.O. and their friends at Kew announced in the Coming Events of the T. & T. JOURNAL last month was a huge success. If the editor could manage to squeeze in the full list it would be a very useful and interesting and almost historical list which it will surely not be able to repeat, but alas! he cannot, and a selection of names would prove invidious. It must therefore suffice to record that everyone spoke highly in praise of the organising and painstaking efforts of Mr. C. S. Keen which produced the above-mentioned satisfactory result.

J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

Telegraph Apparatus Development.

THERE are not a few persons who are under the impression that the telegraph system is dead and that the few obsolete instruments that remain will soon be replaced by telephone apparatus.

If anyone holding such views had been present at the Royal Society of Arts on May 24 he would have been astonished at the rate at which the development of telegraph system and apparatus is taking place. Mr. Lack gave a most interesting and useful summary of recent developments in the science of telegraphy, and illustrated his lecture with exceptionally good lantern views of the pieces of apparatus that he was describing. Mr. Lack is to be congratulated on the arrangement of the apparatus for photographing purposes, as well as in the matter of the paper.

It is a fault of some authors that they pay too little attention to the lantern slides, and leave this matter to the photographer with the result that although an excellent picture may be obtained, the special and distinctive features are not brought clearly into view. It is thought possible that Mr. Lack and the photographer had many heart-to-heart talks before they could agree as to the best view, but in any case the result was very satisfactory.

The audience was impressed by the ingenuity of the mechanism and the quickness of telegraph inventors to apply the most recent scientific discoveries to telegraph purposes.

An engineer who is specially engaged upon telephone work may be excused if he becomes so engrossed in grappling with the problems of his rapidly expanding art that he considers his subject the only one that matters. For instance, he is inclined to look upon the development of the three electrode valve only as having important application to telephone working. Mr. Lack, however, was able to show that this valve has already been adopted for use in telegraph working and that a scheme for doing this had been developed in the Research Section of the Engineering Department.

Although machine telephony involves the use of much mechanism there is as yet much less intricacy and variety than there is in machine telegraphy. Some of the movements in the latter are remarkably beautiful and many of the audience would have liked to linger over certain instruments, but the field which Mr. Lack had set himself to cover was so large that he found it possible to make only passing reference to items which were worth the devotion of a whole evening. If telegraphy be in its old age then it is a very vigorous old age, and use must have been made of the thyroid gland injection to bring back the spirit of youth.

It is hoped that it will be possible to print the paper in full for the sake of those who, although interested in telegraphy, have not been able to closely follow its development stage by stage, owing to absorbing interest in other work.

Threadneedle Street P.O.

A photograph of the existing Post Office building appeared in last month's Journal with a notification that it is to be demolished and a new office erected. It is understood that the new building will be one of the tallest in London. The basement, ground, and first five floors will be in use in connexion with the Post Office. The three top floors will be leased to an Insurance Company. The rebuilding is to be carried out in two stages the rear portion of the building being completed first. The premises are adjacent to the Stock Exchange and most of the messages transmitted over the telegraph circuits are in connexion with Stock Exchange business. There are approximately 30 telegraph circuits terminating in the Instrument Room, most of them being direct lines to Provincial Offices fitted with high speed apparatus. There is a complete installation of secondary cells in the basement. A number of tubes connect the office with the Central Telegraph Office and the Stock Exchange.

One room is given up for use as a public telephone call office, and contains 12 cabinets. When the new building is complete, in addition to the public call office, it will contain a room with a suite of cabinets for the use of Stock-brokers who will gain entry to the room direct from the Stock Exchange. This will complete a scheme in connexion with the provision of call office facilities for the Stock Exchange which was started in 1914.

There will be a considerable amount of work for the London Engineering District to do in keeping the whole of the installations working during the rebuilding operations and in fitting up the apparatus in its permanent quarters. Pending the completion of the new Instrument Room the circuits will work in a temporary Instrument Room in an adjacent building.

Improvements.

It was noticed with pleasure that several members of the London Engineering District have been successful in obtaining awards with respect to suggested improvements in plant and apparatus during the six months ending March 31. It will be seen from the Post Office Circular of May 17 that the suggestions cover a wide field and indicate that interest in the efficiency of the service is being displayed in all directions. Men who handle apparatus day by day and whose duty it is to remedy defects therein are in an exceptional position to suggest modifications with a view to remedying shortcomings in design. Such suggestions are very carefully considered by the Committee appointed for the purpose and the fact that some are not adopted should not dishearten their originators. Clearly there may be good reasons which are not obvious to an officer suggesting an improvement why it should not be adopted when considered from the broader point of view by a Committee surveying the need of the country as a whole.

An interesting announcement was made at the Annual General Meeting of the Institution of Post Office Electrical Engineers held on May 24 to the effect that Lieut. Col. Booth, whose valuable work in connexion with the Baudot Telegraph System is well-known, has handed over a sum of £100 for the formation of a fund from which an annual award will be made to the originator of the most valuable suggestion relating to improvements to the Baudot System.

A Suggested New Society.

If the wives of Post Office engineers ever scan these notes they will not agree with the hopes of the writer of the previous paragraph. An American is credited with the statement that "Life is just one blamed thing after another." If, in the homes of some officials, the husband has time to do a little household carpentry, gardening, and even (whisper it gently, Louise) lend a hand in spring cleaning, why cannot the P.O. engineer do likewise? He always appears to have technical papers, magazines and books that he really must read and, when the bottom of the pile is nearly reached, a fresh supply comes to hand.

It is rumoured therefore that in order to secure the use of a little of the time which the husbands spend away from the office the wives and children are forming an association for the suspension during one year of the publication of all technical literature and reports of recent inventions.

Annual Outing.

After an interval of six years the External Engineers of the District renewed acquaintance with the scenes of former expeditions—Ashbridge Park, West Herts. The journey this year was made by road and was a great success. Assembling near Paddington Exchange at noon on Saturday, June 4, the party proceeded by motor coach through Edgware, Elstree, Hemel Hempstead and Little Gaddesden to what is known locally as Ashbridge Monument. Travellers on the London & North Western Railway may observe this monument showing above the trees on the high ground to the north of the railway in the vicinity of Tring Station. It was erected to the memory of the Duke of Bridgewater, father of Inland Navigation. The scenery in the neighbourhood is very beautiful. The return journey was made *via* Berkhamsted, Watford, Rickmansworth and Harrow to the starting point which was reached at 8.30 p.m. An excellent dinner was served at the Swan, Hemel Hempstead, and tea at The Crown, Berkhamsted. Notwithstanding a somewhat threatening sky the day passed without rain and everybody went home happy.

A Literary Test.

As a test of literary knowledge our traffic colleagues are invited to say from which author the undermentioned quotations have been taken. It may be of assistance to state that the writer in question, although not a member of the London Engineering District, was at one time wont to haunt the neighbourhood where the Denman Street offices now stand. A further clue can be obtained by reading the article by Mr. Heath on Denman Street and its surroundings, which appeared in the May issue.

"Traffic confound thee if the gods will not"

"If traffic do it the gods do it."

"Traffic's thy god and thy god confound thee."

PRESENTATION TO MR. MOIR BY THE STAFF OF THE LONDON ENGINEERING DISTRICT.

OTHELLO : "I have done the State some service and they know it.
"Speak of me as I am, nothing extenuate, nor set down aught in malice."

The present Head of the London Engineering District will terminate his services with the Post Office on July 31. On May 31 representatives from all grades of the staff of the district attended a pleasant little gathering at which Mr. Moir was presented with a grandfather clock, silver salver and gold mounted walking-stick, and Mrs. Moir with a diamond and platinum brooch. The fact that nearly 3,000 members of the staff of the district contributed towards the presentation is indicative of the regard with which Mr. Moir is held by those under his control.

The Chairman, Mr. G. F. Greenham, opened the proceedings by outlining a specification for an ideal Superintending Engineer, which he claimed the retiring one was, and wished Sir William success in his task of selecting a successor to Mr. Moir. He took the opportunity of thanking Mr. Moir publicly for the fair way he had dealt with the transferred staff which had resulted in the two groups of men in London being welded together in one efficient whole in a very short time. He suggested that the energy which Mr. Moir had continued to display in face of his impending retirement was an indication of the disinterested outlook which characterised his work. He still took an absorbing interest in schemes which could not mature till long after his period of office had terminated.

Mr. Gibbons, speaking on behalf of the Executive and Assistant Engineers, said that Mr. Moir had been doing work that had formerly taken three superintending engineers to do. He was particularly interested to know how Mr. Moir was going to occupy his leisure and referred to the hobbies of other officers who had retired from the service during the last few years.

Mr. Cooke, speaking on behalf of the Clerical Staff, paid tribute to the Superintending Engineer's strong sense of justice and stated that although Mr. Moir had a certain amount of reserve yet that reserve covered a large heart. He referred to the strenuous days of 1912-13 when the London engineering district was being moulded into its present form, and to the tremendous capacity for work that Mr. Moir displayed in those days. The Head had high ideals which he expected the staff to live up to.

Mr. Boulton, representing the Inspectorial Grade, said that in his opinion Mr. Moir combined in his personality some of the finest qualities which go to make up character. Mr. Moir could pride himself on being a successful organiser, as was proved by the data and statistics available in the district. He suggested that a knowledge of the fact that he had won the esteem and warm regard of the staff would be more satisfactory to him than the bestowal of any gift or honour.

Mr. Rose, speaking on behalf of the Skilled Workmen, had learned to respect Mr. Moir as a Superintending Engineer and love him as a man. He referred to the good work that was being done by the Whitley Committees in bringing the staff into closer touch with the higher supervising officers. The feeling amongst the men was that they had only to take their troubles to Mr. Moir to get them settled satisfactorily, and that although they did not always get their own way they were sure of justice.

Each speaker in turn expressed the hope that Mr. Moir would live long to enjoy the leisure which he has so well deserved.

Sir William Noble in asking Mr. and Mrs. Moir to accept the gifts from the staff, said he had known him since he was a boy. He agreed that Mr. Moir conformed to the specification outlined by Mr. Greenham. He had made a wonderful success of the London Engineering District which formerly had been under the control of three superintending engineers. Mr. Moir had carried on the work single-handed despite the large accession in the responsibility due to the transfer of the National Telephone Co.'s staff.

Mr. Moir, in thanking the staff on behalf of himself and his wife, said that he found it difficult to express in adequate words the great kindness that had been shown to him by the presentation of such handsome mementoes. He had been in the Department's service for something like 47 years and had seen many great changes take place. He referred to the great strides that had been made in the business of the engineering department and to the great improvements there had been in regard to the welfare of the staff, particularly in connexion with accommodation. He referred to the many occasions on which it had been his pleasant duty to compliment members of the staff for satisfactory work done or to present them with medals in the King's name. He felt that perhaps he had not always expressed his appreciation of the efforts of the staff as freely as he might have done, but he had been brought up in the Victorian Age and had been taught that "Virtue is its own reward." He was looking forward with satisfaction, but with some regret, to the fact that one morning in a few weeks' time he would wake up and find himself not in control of a staff of 6,000 men and women, but only one, viz., his wife. The least he said about the control in that case the better.

In again thanking the staff on behalf of himself and his wife he expressed the hope that the future might hold much prosperity for them all.

LONDON TELEPHONE SERVICE NOTES.

New Rates.

By the time these notes appear the revised tariff will be in full operation and the difficult transitional period, if not forgotten, will at least be left behind. The task of transferring more than 170,000 lines in London from the old to the new tariff was a "full size" job and it can be claimed that it has been well done. When it is considered that the work was additional to carrying on the every-day service we think a "night's repose" has been earned, but the telephone business does not permit of such laxity.

Opening of Chancery Exchange.

Chancery Exchange, situated in High Holborn, was opened at 2.30 on May 28 with the transfer of 520 lines from the neighbouring exchanges, City, Central and Holborn. The opening went off quite smoothly, in fact, almost like the proverbial "house on fire," seeing that in the early hours of the following Monday morning the Fire Brigade were summoned on an alarm of fire which happily was of little consequence. The opening of this exchange did not remain unsung in the Press, for one of the evening papers favoured us with a leaderette. Up to the time of going to press, we have been unable to determine whether the paper's humorist was instructed to write a telephone article or their telephone expert to write a funny one.

Post Office Ambulance Corps.

On Monday, May 30, at King Edward's Buildings, the Postmaster-General presented the awards made by the St. John's Ambulance Association to members of the P.O.A.C. Mr. Kellaway handed to the recipients 115 labels, 30 pendants, 14 medallions, 19 vouchers, 65 First Aid Certificates and 3 Special Certificates awarded for Air Raid duties. The women's trophy and medals were awarded to Miss Alice L. Drewe's G.P.O. South team. The Postmaster-General congratulated the corps upon its successes and remarked upon the elevating influence of work done, not for reward, but for the love and benefit of one's fellows. He said he felt it a privilege to be associated with a function of such a character on the occasion of his first contact with the staff in his official capacity.

Dr. Prynne presided, and Mr. G. E. G. Forbes, Secretary's Office, Miss Buchanan, Savings Bank, Mr. C. Sanderson, Controller, London Postal Service, and Mr. Page, Foreign Section, spoke during the evening.

We are told that the recipe to ensure winning an ambulance award, and especially the coveted trophy, is first to take 5 enthusiastic members of the P.O.A.C. and mix them well together, add one whole course of study of the First Aid Manual. When the proper consistency is reached, place before the fire of examination. The three best teams surviving this ordeal are then placed before the public in competition and the one showing the best response to cries of HELP ! ! ! (heard off) wins.

Light on the Wrong Number Trouble.

In a recent issue of *Punch* it was remarked that on the removal of a telephone instrument from a subscriber's premises 23 wrong numbers were found in its crop. Telephonists will be interested to learn of this authoritative confirmation of their suspicions that a crop of wrong numbers might one day be discovered at the subscriber's end.

Woolwich Exchange.

Dr. A. Webley, the exchange medical officer, has again invited the staff to make use of his tennis court this summer. This kindly act is much appreciated by the staff, and their happiness is increased on the many occasions when Mrs. Webley finds time to join them in a game.

More Phonetic Similarity.

The other day a subscriber complained that an officer of the department had called him a fool. The complaint was investigated, and it transpired that in course of conversation over the telephone in connexion with the signing of an agreement, a contract officer had intimated to the subscriber that his "full" name should be given. Merely a matter of accent.

Belgrave Social and Athletic Club.

An all-day river trip from Richmond to Chertsey has been arranged for Sunday, July 24. The Hon. Sec., Miss N. Williams, of North Exchange, will be pleased to give full particulars to anyone interested.

Retirement of Miss A. A. Heap, I.S.O.

Miss Heap retires at the end of the month after an official life of over 40 years, the last 20 of which she has spent as a Superintendent in the London Telephone Service. She was responsible for the recruitment and training of the operating and supervising staff in the earliest days of the Post Office Telephone System in London. Then, and at every subsequent stage, she has taken the keenest interest in the development of the Service and the welfare of the staff. Many who have worked with her have accepted other responsibilities and are to be found in homes (well ordered, without a doubt) up and down this old country and, indeed, the world over. If these notes meet the eyes of any such they will be glad to know that the present members of the L.T.S. are actively engaged in preparing for Miss Heap a fitting tribute of their regard and admiration. Miss A. M. Webb, of the Carter Lane School, G.P.O., South, will gladly acknowledge any contributions old friends and fellow workers of Miss Heap may care to send.

Congratulations to Miss Heap upon the distinction of being decorated by His Majesty the King with the Imperial Service Order in the Birthday Honours List.

CONTRACT BRANCH NOTES.

CONTRACT Notes have been "conspicuous by their absence" from the JOURNAL of late, not from apathy, but by reason of the tremendous amount of work entailed by the revision of rates. It is not at the moment possible to go into figures very deeply, but a general review of the situation from a contract branch point of view might be interesting.

It should be borne in mind that the only exchange line cases dealt with by that branch are those where the subscriber has decided to allow his agreement to cease, cases where it is found that the actual signatory to the agreement is not using the service, cases of any doubt whatsoever and, worst of all, those cases where the subscriber shows absolute indifference to the department's letters and telephone calls.

The calling officers generally have been received with civility, but with arguments which plainly show the power of the Press, it being obvious that the subscribers' minds have been moulded on arguments gleaned from the newspapers, arguments which the contract officers are easily able to overcome.

A great loss of time and money has been occasioned by the Press outbursts, and their statements, although in most cases literally true, have been such that the full story has not been disclosed and the subscriber has not appreciated its true value.

Take one argument.—A paper stated that if a subscriber in a certain district had 400 calls per annum, each call would cost 6*d*., "the price of a pre-war telegram." This ignores the fact that a reply is included in the telephone charge and that an extra 6*d*. would have to be paid if a reply telegram were used. A telephone message provides for the sending of the message, its answer, and a three-minute, at least, conversation, in one operation. This is quoted only as an instance of the unfair methods of criticism adopted by those who should be above reproach.

In many instances it is stated that the cost under the new rates would be too heavy, and we have lost subscribers owing to this, but there is no doubt whatever that within a very short period the person who ceases his line for such reason will find that it is necessary to re-instal the circuit or lose his place in the running for business.

The present state of industry has had a marked effect on small traders but with the revival of business there is no doubt that a rush will be made upon the service, and even at the present moment applications for new service are being received by their hundreds.

As might be supposed the strongest protests come from late unlimited subscribers, and it is only human nature to object when one, after having received something for less than cost for so long, now has to pay for it. These subscribers generally will not listen to arguments as to the equity of the charges, and yet not one of them would presume to offer the Post Office £20 for an unlimited supply of postage stamps. If such a suggestion is made to a subscriber, he states that there is no comparison, ignoring the fact that the department's business is that of message transmission, either by postage, telephone or telegram.

The compulsory ceasing of the unlimited service has had a marked effect on the volume of traffic, to the advantage of the subscriber and the department. In one case the subscriber was irate and insulting at having to make the change. He now states that instead of paying more, his telephone charges will be less, this being brought about by curtailing unnecessary calls.

Then there is the subscriber who would have ceased in any circumstances. Amusing incidents have occurred in this direction. The officer, in making a call upon a subscriber whose wife was unwell, suggested that the absence of the service might cause delay in the arrival of a doctor which possibly might lead to the death of the lady. The subscriber's answer to this argument was—"A thundering good job too." A small shop-keeper was told that the service was practically invaluable in case of fire. He suggested that it would not matter if his place were burnt down as he would then get the insurance money. These arguments come from people whose service would be ceased in any case.

Quarterly payments are highly advantageous to the small trader and the abolition of the surcharge has had a very good effect on the public in general. When agitations have ceased, and departmental officers are allowed to attend to their own business, the service will grow to a greater extent than has ever been anticipated.

The Contract Branch is dealing with the obtaining of private wire agreements at the new rates, and it will probably be found when this work is finished that the percentage of ceasing subscribers exceeds that for exchange circuits, but such cessations are not necessarily a "dead" loss of revenue. Speaking generally, it will be found that in cases where the offices of firms were connected by means of private wires or tie lines, unlimited service lines were rented at both ends, and consequently the existence or otherwise of private circuits did not directly affect the revenue. Now, with a general message rate, the cessation of such private lines means an increase of exchange revenue.

One somewhat amazing feature is the number of firms who have long been paying for private circuits to other firms, and who now state they have not had any business with the other firms for years, and only on the presentation of the new contracts for signature have they realised the existence of the circuits.

The following extracts from letters received from private wire renters may be of interest:—

(1) "May I enquire whether it is the intention of the post office to renew the agreement for the private wire between these two points, and if so, on what terms, and will these terms be inclusive of calls? If not, am I right in assuming that, in addition to the quarterly rental, there will be a charge of 6*d*. for every call of three minutes' duration, as well as the local fee of 1½*d*., making 7½*d*. in all?"

The interesting point here is that the letter emanated from a London newspaper, one, too, that did not lag behind in screaming about the revision of rates.

(2) ". . . wishes to say when the 'phone to stables was placed there was a large family to use it, now for some years only herself."

Later from the same subscriber:—

"The above charge is a swindle. A wire used once or twice a day for an old lady from her house to the old coachman."

There is perhaps in these letters a veiled suggestion that there should be a sliding tariff for private circuits, based on the number and age of the users.

(3) "No private company would be allowed to adopt such an action (*i.e.*, the termination of the old contract) but we are prepared to accept your notice.

. . . This letter will save you the trouble of sending the new agreement."

However, the new agreement was duly sent, and promptly signed at the new rental which was, as it happened, slightly less than the old.

(4) "It is pleasant to find that the statement of alleged unreasonable increases in telephone charges are not always based on fact."

How different is the aspect that a reduction of rental makes in a case.

There were some 9,000 private wire cases to be dealt with in London the annual rental per case ranging from £1 5*s*. for a short power ringing lead to over £4,000 for a long circuit to the Provinces, the average rental per case being about £15.

MISS HEAP, I.S.O.

"A WELL deserved honour" was the comment of all who knew Miss Heap when they learned from their morning papers on June 4 that the King had been pleased to include her name in the birthday honours. The announcement was read by the staff of the London Telephone Service with mixed feelings—joy that their first Superintendent should have been so honoured

(Photograph by F. C. Burnham, Brixton Road.)

MISS HEAP.

regret because they knew that it was an indication of her pending retirement.

Miss Heap is retiring this year after 45 years' service spent entirely in the Post Office. She was a member of the telegraph staff in Manchester

Digitized by Google

from 1876 to 1901. During this period she attained to supervising rank and was for a considerable time attached to the Trunk Exchange in Manchester. Her experiences during this stage of her career include the transfer of the trunk lines to the Post Office and the re-organisation necessary after a disastrous fire in the Manchester Post Office.

The Post Office London Telephone System was opened in February 1902, and shortly before that date Miss Heap was appointed to recruit, organise and superintend the work of the women of that Service—a work which she has carried on most ably until the present day.

The Service opened with one Exchange, Central—in a part of the switch room at present occupied by the City Exchange and with a staff numbering 40 persons. It has since expanded until at the present time it comprises 75 exchanges staffed by 6,560 women.

The most notable additions to the service were the transfer of the London Trunk Exchange in 1906 and the transfer of the exchanges of the National Telephone Company in 1912. Not the least successful part of Miss Heap's work has been the welding together of these staffs which now work as one harmonious whole.

The period of Miss Heap's service includes that of the Great War, and perhaps in no department of the Post Office were the effects of that war felt to a greater extent than in the London Telephone Service. It was necessary to recruit and train 6,700 women for the day and night staffs. The night work had previously been undertaken by men, but as the majority joined H.M. Forces during the first months of the war, it was necessary to replace them by women.

Miss Heap has always evinced a special interest in the training of the women not only on their entry into the service but throughout their career. Many remember the pleasure and profit they derived from a series of lectures which it has been her practice to give to all officers at the time of their promotion to the supervisory class—these lectures have been embodied in a book entitled "Advice to Telephone Supervising Officers."

Her standard in all things has been high, and it is to her insistence on the maintenance of this standard that the staff owes many of the things which oil the wheels of their official life—their well-equipped dining rooms, their comfortable rest-rooms and their excellent libraries. Her unusually wide knowledge of literature rendering her well able to give advice as to the most enjoyable books to secure for the latter.

In all things she has associated herself with the outside interests of the staff, and in many led the way. She has been associated with the Telephone Branch of the Post Office Ambulance Corps since its inception, and she kept up a personal correspondence with the members of that Corps who were privileged to join the nursing service during the war.

From 1914 to 1919 she was Chairman of the London Telephone Service Branch of the Hospital Saturday Fund, and it was due to her energy and personal influence that the subscription to that fund increased from £780 to £1,200 during her chairmanship.

She has from time to time contributed to the success of the Telephonist's Society by reading interesting papers. Several members of the staff are this year spending their holidays in Italy, possibly as a result of the very interesting lantern lecture given by Miss Heap for that Society in January last, entitled "A little holiday in Italy."

The crowning success of her association with the staff, outside her official work, was undoubtedly the organisation of the bazaar in December last, the proceeds of which enabled the staff to endow two beds and a child's cot in the South London Hospital for women. The staff have shown their appreciation of her efforts in this direction and of her work on their behalf generally by endowing them in her name and thus ensuring that these shall be a perpetual memorial of the work of their first Superintendent.

But it is as a friend and not as a superintendent that many of the older women will always remember her. Although in the last few years it has not been possible for her to know all the younger members of the staff individually, as was the case during the earlier years, she has always been accessible to them, and many women of her staff, both past and present, have cause to be thankful to her for advice and assistance of a practical kind which have ever been at their disposal.

"To spend and be spent" has always been Miss Heap's practice. Her many friends will not, therefore, be surprised to hear that her retirement is not to be one of entire leisure, she has already been elected to the board of management of the South London Hospital and the Committee of the Dulwich Scientific and Literary Society, and no doubt in a short time other activities will find in her a willing helper.

ROYAL SOCIETY OF ARTS.

The Albert Medal of the Society for 1921 has been awarded by the Council, with the approval of the President, H.R.H. The Duke of Connaught and Strathearn, K.G., to Prof. John Ambrose Fleming, M.A., D.Sc., F.R.S., in recognition of his many valuable contributions to electrical science and its applications, and specially of his original invention of the thermionic valve, now so largely employed in wireless telegraphy and for other purposes.

The Medal was instituted in 1862 as a Memorial of H.R.H. The Prince Consort and is awarded annually, for "distinguished merit in promoting Arts, Manufactures and Commerce."

NEW CATALOGUES.

Siemens' Bros. & Co.—

No. 600.—*Primary Cells and Batteries—Dry and Fluid.*

No. 531A.—*Leclanche Fluid Cells and Batteries.*

No. 531B.—*Electric Cells and Batteries—Fluid and Dry.*

No. 537.—*Dry Cells and Batteries.*

The first (No. 600) is a revised and enlarged catalogue of primary cells and batteries manufactured. It comprises 88 pages of the latest and most complete particulars relating to the principal dry and fluid primary cells and batteries manufactured at the firm's Woolwich Works.

Nos. 531A and 537, are made up to some extent of excerpts from the principal catalogue, whilst the third (No. 531B) has been prepared with a view to meeting the needs of those dealers in and users of these cells who are less widely acquainted with the technical side of the subject and are interested mainly in the more generally employed types of cells. This branch of the electrical industry is one to which Messrs. Siemens' technical staff at Woolwich has devoted a most specialised and unrelaxed attention for upwards of 50 years.

Relay Automatic Telephone System (*Marconi House, Strand*). This is an excellently illustrated catalogue, setting out the advantages of this sytem, amongst which secrecy, flexibility, quickness and reliability are claimed. Directions for calling numbers and for the wiring of the system are included, and some pages are devoted to special points of interest to architects, consulting engineers, contractors and others.

CALENDAR OF COMING EVENTS.

July 6.—Cricket. Elmers End *v.* Cable Room at Elmers End.
" 7.— " S.E. & C.R. *v.* Cable Room at Catford.
" 12.— " *D and E Divs. *v.* Cable Room at Dulwich Park.
" 19.—Centels Sports Association. Sports and Garden Party Grove Hotel, Dulwich.
" 19.—Cricket. *Met. Div. *v.* Cable Room at Dulwich Park.

REVIEW.

The June number of *The Wire*, the magazine of the Royal Corps of Signals, and the official Organ of the Signals' Association, is to hand, and contains amongst other specialised and interesting matter the first instalment of a series of articles on "Notes on the History of Signals," by Colonel-Commandant E. G. Godfrey-Faussett, C.B., C.M.G.

PERSONALIA.

LONDON TELEPHONE SERVICE.

The following officers have resigned for marriage:—

Miss M. H. GLENNIE, Telephonist, Avenue Exchange.
Miss K. MCCARTHY, Telephonist, Avenue Exchange.
Miss B. M. DONALDSON, Supervisor, Class II. Central Exchange.
Miss F. E. LEWIS, Telephonist, Central Exchange.
Miss E. M. MOSELEY, Telephonist, Central Exchange.
Miss E. F. WADDINGTON, Telephonist, Central Exchange.
Miss A. A. PETERS, Telephonist, Museum Exchange.
Miss V. YOUNG, Telephonist, Museum Exchange.
Miss E. R. VAIL, Telephonist, Putney Exchange.
Miss E. DAINTON, Telephonist, Trunk Exchange.
Miss M. POWELL, Telephonist, Trunk Exchange.
Miss J. C. ENGLISH, Telephonist, Victoria Exchange.
Miss E. HAYDOCK, Telephonist, Victoria Exchange.
Miss M. A E. LOCK, Telephonist, Victoria Exchange.
Miss D. S. VENTERS, Telephonist, Victoria Exchange.
Miss L. M. BARNSLEY, Telephonist, Woolwich Exchange.

SUGGESTIONS TOWARDS THE IMPROVEMENT OF THE SERVICE.*

BY J. M. MCMILLAN.

"THE Mirrors of the Service," by a "Lady with a Duster"—such was the writer's choice of a title, but an inexorable committee made a clean sweep of it, saying sternly: "Thou shalt have but one title, 'Suggestions towards the Improvement of the Service,'" and where imagination would have run rio, it now halts and stumbles.

An improved service! How many of us, from time to time, have seen visions and dreamed dreams towards the achievement of this purpose. But alas! We have had to say sadly, with Romeo, "A greater Power than we can contradict hath thwarted our intents." So many of our pet schemes have we had rejected that we approach the subject with increasing diffidence. In the first place, there are many points of view to consider. Suggestions, then, will be many and varied, as the subject appeals to one or to the other.

"Wrong number trouble," say some, "the most unsatisfactory feature of the service at present. Lessen this by the 'stile strip' method of separating hundreds and tens digits by short pauses, thus facilitating the selection of the right 'hundreds' block, practically enforcing more deliberation on the part of the subscriber and operator, and causing the number to be more easily remembered."

"Extend the scheme of automatic selection as applied to order wire groups," say others, "and prevent confusion by limiting the use of the circuit to one operator at a time."

"Insist upon all private branch exchange operators being trained in the London Telephone Service."

"De-nationalise telephones," say the subscribers.

"Educate the subscribers," cry the telephonists.

It is human nature to want to improve, not ourselves, but the other person:—

How doth the little L.T.S.
Improve its rental dates,
It gains more honey year by year,
By putting up the rates.

The sub., upon the other hand,
Would like that climate best
Where deposits cease from troubling
And agreements are at rest.

Telephonists, I need not say,
Would hardly take it ill
If holidays were twice as long,
And T.I. forms were *nil*.

And each of us, and all of us,
Unceasingly aspire
To try to make the universe
The shape *we* most desire.

Let us, however, consider, as an experiment, not our own point of view, but the *other man's*. For instance, a great deal has been said about educating the subscriber, and he *is* being educated—by means of the preface to the *Directory*, by *Directory* headlines, by occasional propaganda, and, most useful of all, by visits to exchanges. This latter has proved to be of extreme value, and has enabled the subscriber to see the other side of the question, and to appreciate more fully how he gets his service. There is still need, of course, for an extension of educational schemes, and this is being considered. But we must be just to him. After all, he is paying for his service, and has a right to expect a good one. Besides (let me whisper this) he is not *always* to blame, as sometimes we are asked to believe. It may be urged that he can say what he likes, and no "reprisal" is possible. Experience, however, teaches us quite the contrary. The standard expressions are not *really* a handicap. There is quite a lot of scope for resentment or sympathy to be indicated by the use of any one of them. You can send cold shivers down his spine by your "icily regular, splendidly null" rendering of "I am TRYING to get them," or you can

* Paper read before the London Telephonists' Society.

Digitized by Google

make the wilderness of his soul blossom like the rose by a friendly "I am *sorry* you have been troubled." There seems, however, to be a strong case for allowing telephonists to use their discretion when a subscriber has been subjected to extreme irritation, and to reply to him sympathetically in phrases not to be found in the list of authorised expressions. The cold, inhuman "the matter shall receive attention" attitude when a subscriber has been cut off, rung in error, or connected with the wrong number might well give him cause to exclaim—"Put not another sin upon my head by urging me to fury. The time and my intents are savage-wild, more fierce and more inexorable by far than empty tigers or the roaring sea."

He is unreasonable sometimes? Well, perhaps he has made an unlucky speculation; perhaps he has been rejected—or, as the cynic will doubtless murmur, accepted! Don't infuriate him still further. Instead, give him cause to say of you:—

"Her voice was like a sad embrace; the tone of one who can divine a grief, and sympathise." We all want to exercise our imagination more. We want to imagine ourselves in the other person's place.

There is a story told of a noted democrat, Judge French, who in the days of slavery lived on the banks of the Ohio. He asked some of his anti-slavery friends to bring to his office the first runaway negro that crossed the river, as he could not understand why they wanted to escape. This was done. He then asked the slave if he had been ill-treated in any way, ill-clothed, and so on. To each question the slave replied in the negative. "Well," said the judge, "you say you had a kind master, were not overworked, had plenty to eat, good clothes, and a fine home. I don't see why you wished to run away." "Well, judge," said the slave, "I lef de situation dar open. You kin go right down and git it."

We want to cultivate a sympathetic insight into the feelings of others:—

If all the subs. in London town,
And those outside as well,
And all the staff at each exchange
Imagined for a spell,
How much the service would improve
I really could not tell.

Co-operation would prevail
Just as it ought to do,
And timid souls fresh hope would find,
And courage take anew,
And each would make allowances
And take a broader view.

"Everything beginning with an 'M,'" said the dormouse, but our formula is "Everything beginning with a 'C'."

Co-operation; concord; concentration; constructive criticism, and the three cardinal points—courtesy, correctness and celerity—to name only a few of them.

Co-operation! In that word alone lies one solution of the problem. To keep our eyes not only on our own work but also on that of the other person. To realise each other's difficulties, and to remember that all are working to one end. To have "united thoughts and counsels, equal hope, and hazard in the glorious enterprise."

Concord, too, is essential if we would get the best results. Where resentment is felt the service is sure to suffer. To brood over grievances, real or fancied, is the sure way to innumerable errors. Let us be slow to give rise to resentment, and slow to take offence. A sense of humour will do much towards resolving the dissonances of life into harmonies. To be born without this sense is almost as great a disability as to be born blind—so much of the colour of life do we miss—so much more gloom cast over others. A solemn countenance does not add to one's dignity; nor does a smile detract from it. But it would be a monotonous world if it were peopled by one type of human being. There is room for all—the man of action, the dreamer, the serious, the laughter-loving. Let us remember, too, that their weaknesses are ours. "Whatever folly men commit," says Schopenhauer, "be their shortcomings or their vices what they may let us exercise forbearance, remembering that when these faults appear in others it is our follies and vices that we behold. They are the shortcomings of humanity, to which we belong; whose faults, one and all, we share."

To concentrate on the work at one's hand should not be difficult of attainment. Certainly in the busy hour at an exchange it would be almost impossible to do anything but concentrate. But during slacker periods a greater effort is needed, and it is in these slacker times that the danger lies. All of us in the London Telephone Service have every incentive to concentrate. Each is, or should be, doing useful work in the service of the State. "When men are rightly occupied," says Ruskin, "their amusement grows out of their work as the colour-petals out of a fruitful flower." Work interest is needed by one and all.

Constructive criticism. We should welcome, rather than resent, criticism of this kind. To have another opinion on the work we are doing is often of extreme value. We are apt to look at our own work too closely to get the right perspective, and to have light thrown on it from a different angle will often enable us to see wherein we have failed in some particular. It is only when criticism is uninformed and ill-natured that we object to it, and rightly so. A good deal of it in the papers at present seems to have its base on shifting ground:—

First Pressman (morosely): "The service is not so good as it used to be."

Second Pressman (gloomily): "It never was!"

"You know who the critics are," says Disraeli, "the men who have failed in literature and art." And Burns refers to them as "cut-throat bandits." Some of the recent comments on the service suggested the following verses to the writer:—

Three critics on a winter's day
Racked their brains for things to say.

The editor, in accents solemn,
Had said, "I want a deadly column.

Just write the worst that you can do,
I care not if it's false or true.

I care not if it's wrong or right,
Or full of rancour or of spite.

If undeserved and quite unjust—
But write a bitter one you must."

He ceased; and then the critics three
Uncorked their vitriolic glee.

Their pens unsheathed, and with a yawn
Invented things till day did dawn.

And when they'd done, there was no trace
Of a single thing that had taken place.

Of all sad words which are said of you,
The saddest are those which are not true.

"These lies are great," the editor said,
And patted the critics on the head.

"The service the worst in all the land?"
And he shook them fondly by the hand.

Alas for us—that such can be
In this fair country of the free.

Oh, better for us, if the critics found
Themselves (like their arguments) underground.

Oh, better for all if the yellow press,
Were sent to eternal nothingness.

If the criticism is deserved let us do our best to remove the cause. If undeserved, let us cast it back into the oblivion from whence it came.

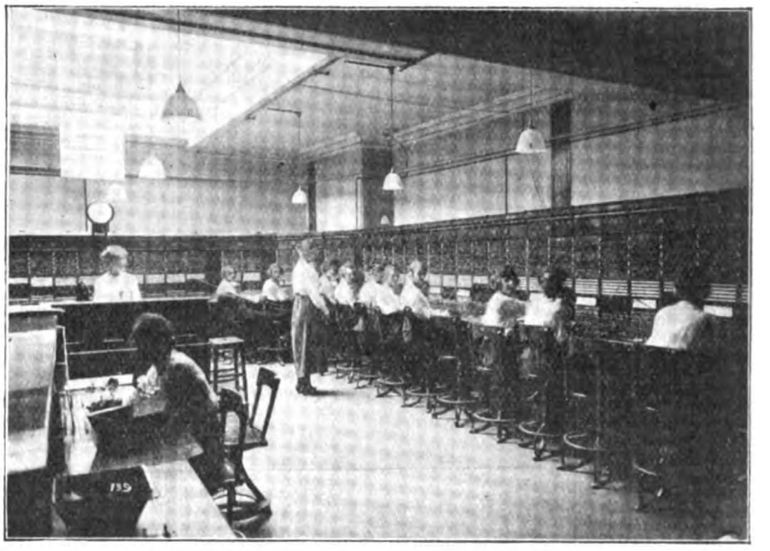
Digitized by Google

It is not necessary to do more than touch on the three cardinal points, so often have we been reminded of them. To be unfailingly courteous, under any provocation; to be as accurate as it is humanly possible to be; and, after accuracy, to work as quickly as possible. Such is our aim and ideal.

The future then is not dark. The service *has* improved, and is improving. Let us remember that the undaunted spirit of the telephonists, the spirit that overcame the enormous difficulties of the past, is with us still. The spirit that helps so cheerfully and willingly the boys at St. Dunstan's, the War Seals Foundation, the Disabled Soldiers' Fund, the hospitals, and many kindred institutions; the spirit that raised over £2,000 in two days, bringing an ambitious venture to a more than successful conclusion—a venture, I think it will be agreed, which could not have been carried out by any other body of women in the world. With this spirit of enthusiasm and loyalty breathing through the service we have no right, no cause to despair.

> Let pessimists grumble, and pressmen upbraid,
> Each gloomy surmise, like their ink, will soon fade.
> *Trust* the telephone staff, and you'll find they'll respond,
> To the very last ditch—and a long way beyond.

And, with this spirit to help us, to quote the Prince of Wales, "Whatever may be the difficulties, we will overcome them, and pull through."



"CHANCERY."

ANOTHER EXCHANGE ADDED TO THE LONDON TELEPHONE SERVICE.

BY C. MARLAND, L.T.S.

STEADILY the expansion of the London Telephone Service goes on. In spite of all the charges that are made against it of being re-actionary and moribund it continues to grow. During last year expansion took place at the rate of 10 per cent.

New cables have been laid down and new exchanges built with all the speed and expedition that was possible considering the difficulties which had to be faced in obtaining materials. In central and suburban areas where insufficient switching exchange plant was the barrier to immediate acceptance of contracts new relief or permanent exchanges have been designed and constructed. Old subscribers are being transferred to the new exchanges wherever it has been necessary to make room for new subscribers within the area of the old exchange. Clerkenwell, Broadway, Latchmere and Langham have been added recently to the list of over eighty exchanges which come within the boundaries of the London area. Now "Chancery" is added, and gradually this new name will become familiar to people who use the telephone, particularly those in the vicinity of Chancery Lane. That is the place which has given its name to the new exchange. It is necessary to go far afield in imagination sometimes to find a suitable name for a telephone exchange, and on one occasion many years ago a test call was passed in all seriousness for "Higgle-de-piggledy, Kingsbury" in order to test the phonetic possibilities over the telephone of "Kingsbury" as the name of an exchange. A name for this purpose matters much. The subscribers who are transferred from one exchange to another sometimes take strong exception to the change for various reasons. In the case of "Chancery," however, there was not so much objection to the change. The district which it serves is occupied principally by people who are in some way associated with the law, and as Chancery carries a similar association the name was, on the whole, quite acceptable. It may be mentioned, however, that it has already been discovered that Chancery is not completely dissimilar from every other exchange name. If it is pronounced with a short "A" as in "fancy" it is apt to be mistaken for Hampstead. Callers are, therefore, advised to forget their University habit and when calling for Chancery to pronounce it with a ong, soft vowel sound.

CHANCERY EXCHANGE.

The area which the new exchange serves is the square inside Grays Inn Road, Theobalds Road, Southampton Row and High Holborn. It has been designed principally as a relief to Holborn. The latter has been working to its full capacity for a long time, and the necessity for a new exchange in a building erected primarily and solely for that specific purpose was accepted and acted upon. The site of the Inns of Court Hotel in High Holborn has been secured, the old building completely demolished and building operations begun. Quite a few years must elapse, however, before

CHANCERY EXCHANGE.

it is completed, and in the meantime Chancery has been brought into use to tide over the period before the new Holborn is ready for service. Like its parent exchange, Chancery is not provided with a home of its own, but is accommodated as a kind of afterthought in a house built for other purposes. Just as Holborn is

Digitized by Google

marvellously tucked away up on the fifth and sixth floors of the suite of offices formerly known as Birkbeck Chambers and now called Bank Chambers, so is the new exchange to be found in an unexpected situation, namely, on the first floor over a new Slater's

REST ROOM, CHANCERY EXCHANGE.

restaurant at 55 and 56, High Holborn. The ultimate capacity of the exchange is 1,560 subscribers' lines, of which 524 were joined for the opening, 376 being transferred from Holborn, 118 from Central, 28 from City, 1 from Museum and 1 fire line. The opening took place at 2 p.m. on Saturday, May 28, and in spite of certain misgivings and fears there were no untoward incidents or happenings. The preliminary spade work which always precedes such an event had been well done and at the psychological moment when the fuses connecting to the old exchange lines were expeditiously removed by a relay staff of engineers and the elastic rings in the cut off relays were released simultaneously by a locally improvised device all eyes were instantly turned in the direction of the switchboard. A sigh of relief was felt when it was noted that the answering field was *not* on fire. Only one or two lamps lit up. Calls to Chancery

TEST ROOM, CHANCERY EXCHANGE.

had actually begun. To be prepared for these the staff answering subscribers' calls had been interspersed with those who were to carry out tests. The latter had been provided with forms on which the results of the tests could be easily recorded and speedily summarised. At the conclusion of the first test at 3 p.m. it was found that there were—

7 exchange faults,
3 line faults,
1 junction fault.

At 5 p.m. there were—

3 line faults,
1 junction fault.

Grave doubts had been entertained that the change of voltage involved in the transfer would possibly upset the balance of the circuits. A special test for low insulation was, therefore, carried out, the result of which was quite reassuring. Only eight cases of low insulation were revealed.

Something more serious happened, however, on the day after the opening. In the early hours of Sunday morning smoke permeated to the switchroom and it was discovered that the power room was full of thick smoke. With commendable promptitude the night telephonist in charge called the fire brigade, who were quickly in attendance. Fortunately, however, the smoke did not develop into flames. No damage at all was done beyond the burning out of the battery choke coil which was the cause of the smoke.

The sister exchange to Chancery is Langham. Apart from a slightly different lay-out of the switchboard necessitated by the configuration of the switchboard Chancery is an exact replica of the Langham board. It is of the C.B.10 type very clearly marked and numbered, and having a four-panelled multiple. The numbering of subscribers' lines begins at 7,000, so that when these circuits are again transferred to the new Holborn it will not be necessary for a further change of number. Sixty subscribers can be accommodated on each A position. There are twenty-six A positions and eleven B, one testing position, four positions on the Information desk and a chief supervisor's desk. The chief feature of special interest in the test room is the combined main and intermediate frame, which is shown in the accompanying photograph. The testing apparatus is accommodated on the same floor as the switchboard, and owing to the structure of the building it monopolises all the light from the spacious windows overlooking Holborn. The switchroom depends for its daylight upon the lantern light which extends over only a part of the room, and except on very bright days the B board has to be lighted with electric light.

The combined sitting-room and dining-room has a very cheerful aspect, commanding as it does a good view of any pageants which may be passing along High Holborn.

The supervisors and staff who have been transferred to Chancery are all gratified at the successful opening and appear happy and contented in their new official home. They are working with that *esprit de corps* and good will which makes for efficient service and a satisfied group of subscribers. This new exchange may be of interest to others, but it means most to the people who will be served by it. And it is hoped that the name Chancery will be a synonym telephonically for happy and efficient relationships both within and without the exchange, serving well those who pay for its service and doing credit to the huge organisation of which it now forms an integral part.

THE BAUDOT.—XXIII.

BY J. J. T.

FIGS. LXIII and LXIV should make the adjustment mentioned in the last article even more clear. These should not, however, be confused with Fig. LXII. The reader has by this time gripped the idea that the selector levers cannot be actuated during the passage of the selector N and its cams KK^1 (Figs. XL and LXIII), and that the ideal position for KK^1 is as far away from the levers as possible. Further, that if, as in Fig. LXIII, KK^1 should be found in any *other* position than that just indicated, say at BB *when the circuit-closing cam* K^4 *is in the exact position as regards d*

Digitized by Google

of the lever L as there shown, then it will be necessary to bring KK¹ into the position marked B in the same figure. KK¹ is, however, a fixture upon the combiner wheel as we have seen, and the problem of how to maintain the relationship is solved by simply moving K⁴ through a space equal to the angular difference between the correct and incorrect positions. In the case before us through an angle equal to the angle YXZ, and in the direction opposite to the direction

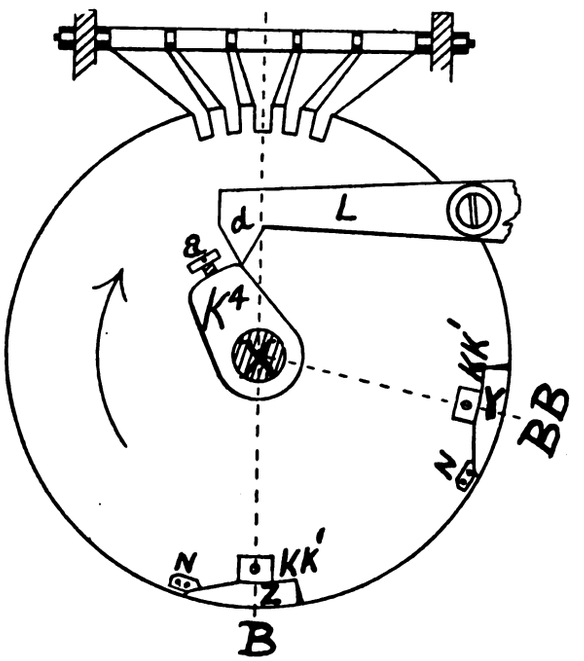


FIG. LXIII.

of rotation indicated by the arrow. The relative position of the receiving and brake brushes to this mechanical relationship is indicated in Fig. LXIV. That is to say, when the brush of Ring II is in the middle of the third segment F the brush of Ring III should be in the middle of the brake segment E allocated to the corresponding receiver, KK¹ being at B and K⁴ as shown in relation to the circuit-closing *lever* L.

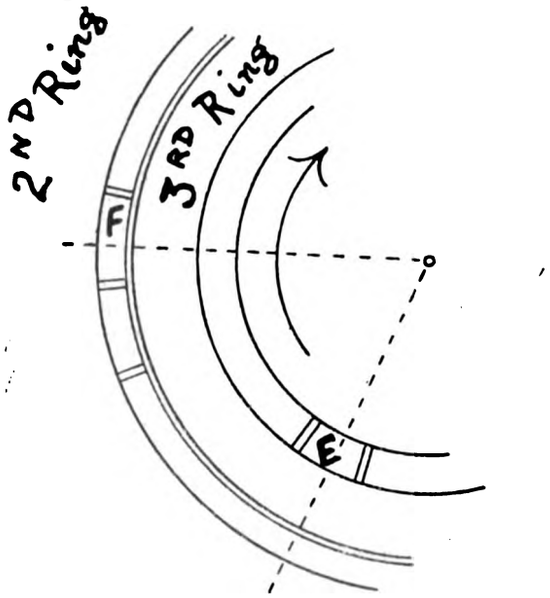

FIG. LXIV.

Figs. LXV and LXVI give views of a later type of brake adjustment and one now generally adopted. Some of the differences between this type and that shown in Figs. LX and LXI are self evident. Tension is given to the armature B by a long flat spring R (Figs. LXV, LXVI) screwed at right angles to the vertical brake piece A at M, below the base-plate W, R being adjustable as regards its tension by means of the screw V (Fig. LXV).

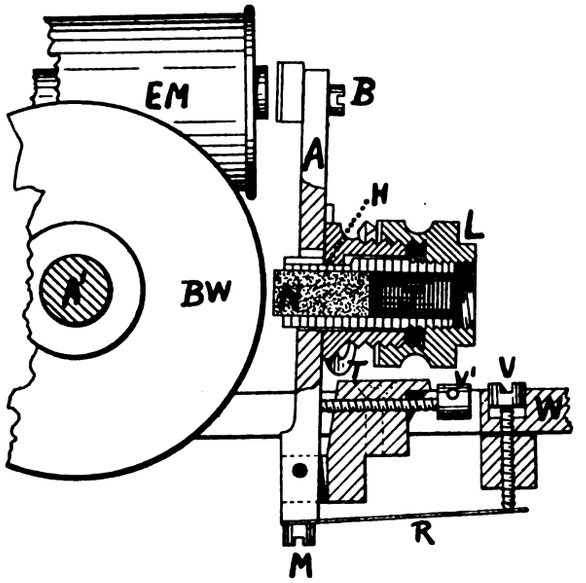

FIG. LXV.

The adjustments of the brake armature are specially ingenious and interesting. To the vertical piece A is fitted a projecting tube K (Fig. LXVI) cut with a right-handed thread on its exterior surface. The interior is channelled and into this glides the catch H of the cylinder J (Figs. LXV, LXVI). The interior of the latter is very finely tapped in order to hold the projecting cork-brake N which is equal in diameter to the thickness of the brake wheel BW. The other end of J is cut with a left-handed thread half the gauge of that of the tube K. L is a large screw consisting of two threaded parts; the smaller thread is the same as that of the cylinder J with which it engages and the larger thread is of the same gauge as

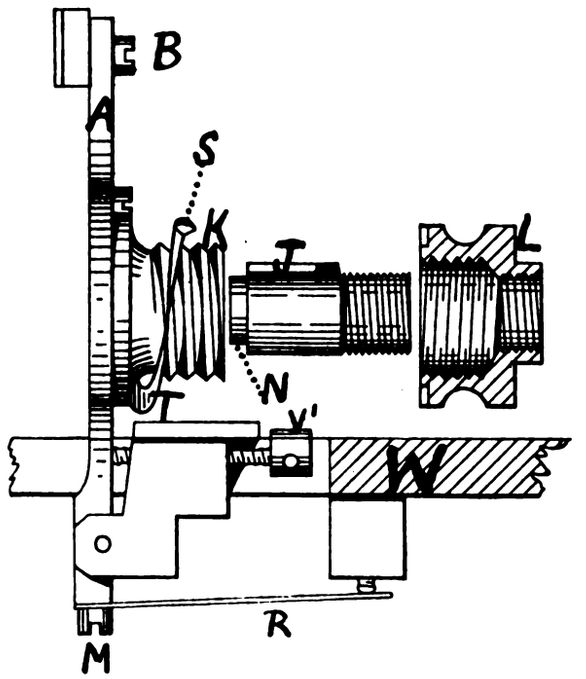

FIG. LXVI.

that of the tube K. This screw L carries on the side facing the armature piece A a number of radial slots. A small steel spur S fitted to the free end of a flat spiral spring T engages with the slots on the face of L as the latter is screwed up towards A and thus holds L in any given position.

Digitized by Google

The adjustment is as follows: Having taken off the screw L the cylinder J is screwed almost into the end of L. Then the reverse end is inserted into the tube K, and the catch H into the channelling of J. If L be now screwed inwards, L will progress towards A over K, but will *unscrew* as regards the cylinder J which latter cannot turn on account of the catch and channelling. The gauges of the screws are in the ratio of one to two and it therefore follows that if for example an advance of two millimeters of the screw L is made the brake-stop carrier J will only move one millimeter. This arrangement gives a specially fine and yet sturdy adjustment. Once fixed the adjustments of the armature piece A made by means of the screws V and V1 should not need to be touched.

(To be continued.)

HISTORY OF THE ANGLO-CONTINENTAL TELEPHONE SERVICE.

(*Continued from page* 148).

III.

TELEPHONE service with Belgium and France was not re-opened to the public until the 27th and 28th October, 1919 respectively. By that time it was found possible to release certain of the circuits in use by the War Cabinet, the Peace Conference, and the Ministry of Shipping, and service to France was commenced with 5 circuits to Paris and 1 each to Dunkirk, Lille and Boulogne. One circuit in the second St. Margarets-La Panne cable afforded communication with Brussels, but early in 1920 a second circuit was brought into use, and the service extended to Antwerp. The pre-war tariff remained in force for both services, but in the case of the Anglo-French only provisionally. Owing to the increased cost of materials and wages it was agreed by the French and British Administrations early in 1920 to raise the charge for calls between London and Paris from 4*s.* to 6*s.*, and proportionately between the provincial towns of the two countries.

Two additional circuits to Paris were released before the end of 1919, another was brought into use in April 1920, and another in October making 9 in all, which with 3 lines transferred from the Astoria Hotel to the Paris trunk exchange made a total of 12 available circuits in the autumn of 1920, about which time the Dunkirk circuit, which was little used, was discontinued. The ex-Astoria circuits, however, only worked intermittently, and indeed seldom more than 7 of the circuits between London and Paris were working at the same time. The maintenance of the French land-lines presented a problem of considerable difficulty to the French Administration. These lines pass through the devastated area, and moreover some of them were originally in the nature of temporary military lines constructed by the British Signal service out of local material. Repeaters have been inserted on some of these circuits, and the French Government have in hand the work of rebuilding others, and at the time of writing 9 or 10 out of the 12 circuits to Paris are usually available each day in addition to the circuits to Calais, Boulogne, and Lille. The latter line carries most of the traffic for Northern France.

Reference has been made to the insertion of repeaters, which seem to be destined to play a great part in the future of international telephony. The thermionic valve repeater was studied and developed largely during the war for military purposes. Rapid as that development was it has only reached full attainment since the war. The use of these repeaters has not only extended indefinitely the possible range of telephonic speech, but has also enabled the amount of copper employed in the circuits to be greatly reduced, thus providing a considerable offset to the enormously increased prices of material. For instance, instead of using 300 lbs. of copper per wire to the mile as in the London and Liverpool trunk cable, it has been possible to use 40 lbs. of copper in the new London-Manchester cable, with equally good results. Although communication was nominally afforded with the south of France before the war, the speaking was undoubtedly difficult, but now, by means of repeaters, speech with Marseilles and Bordeaux has been rendered entirely satisfactory and the service has recently been extended to Toulouse. In addition communication between France and towns in the North and West of England has been improved by the same means. In October, 1920, the service was extended to Metz, Strassbourg and Mulhouse in Alsace and Lorraine.

Great as are the possibilities of extending the range of telephonic communication in Europe, it is unfortunately impracticable to give effect to them until the needs of the French and Belgian services are satisfied. Congestion at present exists in the traffic both to Paris and Brussels, and any immediate addition to the Anglo-French and Anglo-Belgian circuits would have as its primary object the improvement of communication between London and those places. Not until such improvement has been made will there be an adequate number of circuits available to carry traffic for a possible service with Italy, Germany, or any country beyond. Proposals are under consideration for the provision of further circuits to Belgium, and negotiations have been re-opened with the Netherlands for laying a direct telephone cable between England and Holland. Indeed, the details of the construction of the cable are at present engaging the attention of the respective engineers.

That the traffic between England and France has grown very considerably since the opening of the service in 1891 the following figures will show:—

	Calls.
Traffic in the first day (1891)	22
Average per month 1892	3,018
,, ,, 1895	4,764
,, ,, 1912 (March 31) ...	7,787
,, ,, 1913 ,, ...	9,867
,, ,, 1914 ,, ...	11,735
July 1914 (month before the outbreak of war)	19,963
February 1920	18,336
April 1920	23,939
July 1920	24,111
October 1920	28,252
January 1921	28,278
April 1921	28,579
May 1921	31,496

The Anglo Belgian traffic reached 2,428 calls a month in 1912, and 4,878 in 1914, carried by four circuits. Soon after the re-opening of the public service, 4,306 calls were carried in February 1920 with two circuits. The circuits were increased to three, and 5,296 calls were carried in June and 5,460 in September. 8,000 calls were, however, exceeded in July 1920, and again in February, March and April 1921. The number declined to about 7,000 in May, owing to interruptions to the circuits which prevented full use being made of them.

On the value of the international telephone service in promoting business and social relations between the countries connected it is not necessary to enlarge. What part it played during the war in keeping the Allies in close touch with one another and headquarters in London with the forces overseas we have already seen. On the occasions of international conferences and the like it has proved its value more than once in quite recent times, and the extent of its future possibilities would be difficult to foresee. The language difficulty which gave pause to the early promoters of the service proved to be chimerical and has never retarded the steady development of the traffic. On the contrary the present difficulty is to provide sufficient lines to meet all requirements. When this difficulty has been overcome the expansion of the international service over Europe will only be a matter of time and one of infinite benefit to the nations affected.

W. H. GUNSTON.

LONDON ENGINEERING DISTRICT NOTES.

BEFORE the August issue of this Journal is published the control of the London Engineering District will have passed into fresh hands. Up to the time of sending in these notes no official announcement has been made as to Mr. Moir's successor. Whoever is appointed to this important post may rely on the loyal support of every member of the staff in his task of maintaining the efficiency of the district. The control of a staff numbering nearly 6,000 is no light task, and the problems to be faced during the coming years can only be successfully negotiated by the officers of the district working as a team in perfect harmony and by the exercise of mutual trust and goodwill.

Ineffective Time.

The long spell of fine weather is resulting in a considerable decrease in the number of faults. Fault curves like vegetation are wilting. Although, for the time being, this is a satisfactory state of affairs, the reaction is bound to come when nature starts to adjust the average. Unfortunately, the same weather conditions which tend to produce a large number of faults also make their clearance more difficult, although, thanks to the protective clothing with which the men are provided, the dead time due to adverse weather conditions is surprisingly small. On this same subject of dead time it may be remarked that there is a tendency on the part of some members of the public to assume that every Post Office workman who, when observed, is not obviously engaged in work, must be wasting his and the department's time. This assumption is, of course, due to ignorance, but is none the less disturbing. Gangs comprising various numbers of men are required to carry out the different classes of work that fall to the lot of the Engineering Department to perform. Each unit in a gang has his particular duty, and on some portions of the work every unit in the gang must be simultaneously engaged, although at other times this is not the case. Every endeavour is made to reduce the enforced idle moments, but some are unavoidable. To illustrate the point, take two cases where complaint was received that at certain times men were observed to be idling. Investigation showed that in one case the foreman was giving detailed instructions to the men concerning some intricate diversions and in the other case the men, having completed running a telephone circuit, were waiting for the foreman, who was inside the subscriber's premises having the circuit tested.

It is not claimed that the department's men are free from human failings, but the majority do appreciate that by working conscientiously they are helping to build up a successful business with which they are proud to be associated. They also realise that only successful undertakings can afford to pay satisfactory wages.

Technical Classes.

It may not be generally known that by an arrangement with the Education Authorities special classes are held at the various Polytechnics for the benefit of Post Office engineering workmen. The fees and travelling expenses are paid by the department provided the student's attendance is regular. Most of the instructors are members of the Post Office engineering staff. The scope of instruction is laid down by the department. Although the instruction given at these special classes is not designed to prepare students for the City and Guilds Examinations, yet those who do well in the Second Year Course find little difficulty in obtaining passes for the City and Guilds Examinations. Members of the staff who elect to join the classes designed to prepare students for the City and Guilds Examinations have part of their fees refunded to them if successful in the examinations. They are also entitled to a technical allowance of 3*s.* a week.

The results of the examinations for 1920-21 Session will soon be known. Some 820 students, divided amongst eight Technical Institutions, took advantage of the special classes conducted for the benefit of Post Office workmen. It is anticipated that next Session the pre-war figure of over 1,000 students will again be reached.

Civil Engineers Visit Telephone Exchanges.

On July 1 some 70 to 80 members of the Institute of Civil Engineers, who were in London for their annual conference, took the opportunity of inspecting some telephone exchanges. The three exchanges at G.P.O. South and the Automatic Exchange in G.P.O. West were selected.

Messrs. Ridd and Steed are to be congratulated on the very complete arrangements they made to ensure that the visitors should see and have explained to them everything likely to be of interest. Among the visitors was Mr. Frank Gill, Engineer-in-Chief of the late National Telephone Company.

Another Wise Decision.

In the June issue reference was made to a decision given in a Court of Arbitration by the presiding Judge in connexion with a wayleave case. Since that time the management of a large building let out as offices saw fit to demand an increase in the amount paid by the Department to recoup the owners of the building for any small loss that they might be put to on account of the presence of a pole on the roof of the building in question. Their plea was that the actual value of the sum paid to them was reduced owing to the diminishing purchasing power of the sovereign. In the view of the Department the amount paid was in pre-war days out of proportion to the loss sustained by the owners, the original agreement having been entered into by the late N.T. Co., who, having no statutory powers had perforce to make the best bargain possible with property owners. As the wayleave grantor would not see reason the case was taken to arbitration with the result that in future the company, instead of receiving higher payment will get less than half what they had been paid in the past. There would be little prospect of telephone rentals being reduced in the future if the Department were compelled to pay exorbitant sums for private wayleaves.

North External Section.

A grand variety concert was held on May 6, 1921, on behalf of Mr. J. Groves (Labourer) and Mr. W. Thacker (S.W.II). The former received injuries to his foot whilst on duty, and was in the London Hospital some weeks. The latter has been suffering for some considerable time with internal trouble. He has had several severe operations, which we are glad to hear have resulted in his recovery. Although still very weak he is convalescent, and his colleagues will be glad to see him resume his duties.

The concert was promoted by Messrs. G. H. Gillett and W. Lovell. A tip-top troupe known as the Black and White Concert Party took part, and the rest of the programme was provided by members of the staff, including both internal and external. It was well supported by the staff. The concert was a brilliant success. The net proceeds amounted to £16 1*s.* 7*d.*, which was shared between the parties concerned.

This concert was followed by another a few weeks later, which took place at St. Bartholomew's Hall, Dalston Lane, on behalf of Mr. F. Haynes, on his retirement from the service.

The entertainment was a splendid success, and was made an occasion for presentation to Mr. Haynes of a beautiful clock as a mark of esteem. Mr. Martin, Assistant Engineer, accompanied the presentation with a most appropriate and agreeable speech, and Mr Haynes very suitably acknowledged the gift.

The opportunity was also taken of making some recognition of the services of Mr. J. Warwick, one of the prominent members of the Black and White Concert Party, who is always ready to give his services on such occasions.

Extract from daily paper:—

Baby Left in 'Phone Box.

Hearing the cry of a baby in a telephone cabinet in Victoria District Railway Station, an official opened the door and found a 9 months old girl on the floor. It is understood that all articles found in call office cabinets and not claimed by the owners become the property of the Postmaster-General.

Literary Competition.

The quotations about Traffic given in the L.E.D. notes for July are from Shakespeares' "Timon of Athens."

Back to work again.

Now that the coal strike is over a trade revival should quickly follow. The work of putting down new plant to meet the anticipated demand for telephones is progressing steadily, but there is still a great deal of lee-way to make up. It is to be hoped that the cry for economy will not result in the withholding of funds for telephone plant development, for this will be the surest way to hamper the country's reconstruction. The committee of business men who are to advise the Postmaster-General will no doubt quickly realise that the only hope of meeting the needs of the community is for the Department to concentrate all its energies on the provision of new exchanges and outdoor plant.

Golf.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. AUGUST, 1921. No. 77.

LANGUAGES AND LONG DISTANCE TELEPHONY.

IT will be remembered by those who have read the articles on the Anglo-Continental Telephone Service which conclude in this issue, that the question of difference of language appeared to the pioneers of the London and Paris service—at least in London—to be a formidable difficulty which would have the effect of confining the traffic to comparatively few people. This judgment of the linguistic attainments of Englishmen and Frenchmen has happily been so far falsified that the traffic has nearly always exceeded the carrying capacity of the lines. Now, however, the question has arisen in a new form. An American journal, moved by the recent interesting experiments in trans-continental telephone, re-inforced by wireless speech, says: "What fairy tale could compare with this vision of a world-telephone-system that will make necessary to all nations the use of a common language which will join all peoples of the earth in one brotherhood?" The use of a common language will always, we imagine, be an unattainable ideal, nor is it an entirely desirable one. What country with a cultured and copious idiom, enriched by the literary traditions of centuries would consent to forget or forego its language for any possible commercial advantages? We must attain the brotherhood of nations rather by learning one another's tongues than by trying to force our own language on an unwilling world. It is singular how the study of a language creates a sympathy with the country which speaks it, and we believe that such study is the only true specific for understanding the outlook and ideals of other peoples than our own. Moreover, we do not see that any urgent necessity arises for the use of a common language in international telephony. Although this country at present is in communication with two French-speaking countries only, it should be remembered that continental countries, undivided by miles of sea, speak with all their neighbours and employ widely differing languages. France is in communication with, amongst other countries, Holland, Germany and Italy, and Germany can speak to Denmark, Norway, Sweden, Hungary, Holland and Poland, besides its Latin neighbours. Perhaps the intention of the writer was that telephone users should be bi-lingual, using their own language for ordinary purposes and the universal language for international telephony. But in the adoption of that common language surely insuperable difficulties could arise.

It may be of interest to inquire to what extent the principal languages of the earth are distributed amongst telephone users. Owing to its use in highly-developed America, and in the British colonies, the English language has an overwhelming preponderance. There are, perhaps, some 21,000,000 telephones in use in the world. Of these fifteen-and-three-quarter millions are used by English-speaking people in the Unites States, Great Britain, Canada, Australia and Africa. German comes second, *longo intervallo*, with about two-and-a-quarter million telephone users in Germany, Austria, Switzerland and neighbouring states. French has about 500,000 votaries, Swedish 400,000, Dano-Norwegian 400,000, Japanese 350,000, Spanish 250,000, and Russian 200,000. Even thus some of the most widely spoken languages are but ill-represented amongst telephone users. Populous India and China have not 50,000 telephones each, and in the former case the subscribers are largely European. As for Arabic, which is spoken over a vast tract of Asia and Africa, extending from Bagdad and Muscat to Morocco, and from Algiers and Damascus to Zanzibar, we should doubt whether that language is used to speak over more than 20,000 telephone lines. We give these rough figures that the selector of a universal telephone language may take his choice, and we do not envy him his task.

HIC ET UBIQUE.

A BILL before the German Reichstag proposes the abolition of flat rates for telephones. The new charges range from 380 marks (say £19) per annum in small places with up to 50 lines to 760 marks (say £38) per annum in places such as Berlin. In addition calls will cost 3*d*. each, and at least 40 local calls per month must be paid for. Thus a Berlin subscriber will pay 885 marks a year for 500 calls instead of 880 marks for an unlimited service.

BY a clerical error last month our correspondent stated on page 158 that Sir Andrew Ogilvie had recently been elected an Associate of the Institute of Electrical Engineers, instead of a member of the Council. Sir Andrew has, of course, been an Associate for very many years.

THE *Glasgow Citizen* in commenting on the excellent telephonic development of Australia informs us that at present the Commonwealth has 43 telephones to every 100 of the population. Nearly every other person (babies, school children, wives and mothers included) would thus appear to be in possession of a telephone in that happy land. On examining the figures of Australian development we find that what is really meant is that 43 per 1,000 is the correct ratio. We may say that the trifling discrepancy caused us no undue surprise, as we are well accustomed to this sort of telephone statistics in the Press.

A NOTE in the *Electrical Review* on electrostatic adhesion refers to Elisha Gray's experiments in 1873 or 1874 on the transmission of musical sounds by telegraph. Gray constructed a cylindrical

Digitized by Google

sounding-box with a metal cover and mounted it on a spindle to which a crank was attached. The metal cover was connected to earth through the spindle and the operator held one end of the telephone line in his hand. On rotating the box and pressing the fingers against the cover, while the current was flowing, he says: "the tune that is being played at the other end of the line becomes distinctly audible." Gray proved that the effect was due to electrostatic attraction. On one occasion when he had been sending tunes over a short line using one of the batteries of the North-Western Telegraph Co. at Milwaukee, he was surprised to learn that the tunes were reproduced by the relays in the various offices along the line. "Some of the operators being ignorant of the invention of the telephone at that time, were very much amazed at this new exhibition of the musical powers of their instruments and I am told that one gentleman, 60 miles from Milwaukee, closed his office that night much earlier than he was accustomed to do." It will be remembered, comments the *Electrical Review*, that America had not then become "dry."

"A FEW weeks ago," says the *Cardiff Western Mail*, "I called your attention to the difficulty which confronts wireless telegraphy by reason of the electrical disturbances set up by the despatch of wireless messages. These difficulties will be overcome in the future, but at present I believe that even the strongest wireless installation can only be used some five hours a day. There is now an International Commission sitting to decide how the wireless messages shall be despatched in the future, what air currents shall be used by each country, and how their various instruments shall be tuned up. The air will obviously be cleared if it is possible to create special French, American, and other lines, and this, it is said, can be done by the allocation of certain currents and the tuning up of the various machines. Experts are now at work upon this task."

We presume that hot air currents are referred to.

ACCORDING to *The Times*, it is proposed to raise the telephone rates in Vienna 150 per cent. They are already extraordinarily high and have risen from 480 kronen with 12,000 calls a year in 1919 to 3,600 kronen, for a service including 12 calls a day. At the old value of the krone this would represent £150 per annum, though what it means in spending-power to the Viennese at the present time it is difficult to gauge—24 calls a day cost 7,200 kr. a year (say £300), and 40 calls 14,400 kr. (say £600). An Association of Telephone Subscribers met and condemned the proposal to raise these rates another 150 per cent, threatened a subscribers' strike, and proposed that the telephones should be worked by a private company. It is interesting to remember that the telephone service was originally introduced to Vienna by an English Telephone Company in 1881.

WE heartily congratulate our colleague, J.J.T., on his appointment as a third gallery superintendent to the Cable Room, Central Telegraph Office.

THE Australian press is highly satisfied with the cable service reporting the recent test matches as the following extracts show:—

"The Pacific Cable service," says the *Sun*, "excelled itself when handling our test cricket messages last evening.

The story of the third day's play reached us in messages which travelled from London to Sydney in 24, 25, 24, 24, 29, 20, 30, 27, 22, 37 minutes respectively.

That is to say the news came 13,000 miles faster than the result of a race is transmitted from suburban racecourses to the head telegraph office."

"The cablegrams from London describing the test match play came through to the *Daily Telegraph* (Sydney) office last night in remarkably fast time. The first was received at 9 p.m., and the others came every few minutes, until the luncheon adjournment.

What is known as summer time—under the daylight-saving scheme—is being observed in England, and this means that English time is now nine hours behind Australian. A cablegram from Lord's Ground was delivered in the *Daily Telegraph* sub-editor's room just 20 minutes after it had been lodged. This is certainly smart work on the part of the Pacific Cable Board, which is now handling the messages."

The *Sydney Evening News* has a paragraph to the same effect.

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

BY F. ADDEY, B.Sc., M.I.E.E., FELLOW I.R.E.

(*Continued from page* 153).

Internal Action of a Valve.

BEFORE the filament is heated the space inside the valve offers a very high resistance indeed to the passage of the current of electricity, and a very large electro-motive force is necessary to force any current to flow between the anode and the filament. When the filament is glowing, however, the state of affairs is quite different. With a comparatively small electro-motive force applied from anode to filament, that is, with the anode made positive to the filament, a current will be sent through the valve. If, however, the electro-motive force be applied in the reverse direction, the anode being made negative to the filament, no current will flow.

It has been found, as a result of modern research, that from a heated body, such as the glowing filament of a valve, small negatively charged particles are continually being shot off. These particles seem not to be material bodies in the ordinary sense, but each seems to consist solely of a minute charge of negative electricity. They are called "electrons," and their discovery has revolutionised our views on electric charges and currents.

Before electrons were known, an electric current was, for convenience, said to flow from a body at a so-called positive potential to one at a so-called negative potential. This was, however, a purely arbitrary convention. No one knew whether a "positively" charged body or a "negatively" charged body had the greater charge. When a positively charged and a negatively charged body were joined by a wire, no one therefore could say which way the resulting "current" in the wire actually flowed, or even whether any current flowed at all.

The expressions "positive charge" and "negative charge" were simply convenient names for opposite electrical states into which bodies could be brought, while the expression "electric current" was used to denote the sum total of the various phenomena which were set up in and around a wire, one end of which touched a positively charged body and the other end one negatively charged. Certain of these phenomena were directive, and their direction, or "sense," could be reversed when the positive and negative ends of the wire were reversed. For instance, a compass needle near the wire was caused to twist round when the ends of the wire were brought into contact with the charged bodies, and the direction in which the needle turned depended on which end of the wire was joined to the positive body, and which to the negative. The idea was thus reached of something flowing in the wire in one direction or the other, which caused the observed phenomena. The direction in which this "something" should be said to flow was arbitrarily chosen as being from the positively charged body to the negatively charged one.

It now appears that there is an actual flow of electricity in the wire, but that this consists of a stream of the negatively charged electrons, flowing in the opposite direction to that in which the "current" is ordinarily said to flow. The electrons are in the wire all the time, but they need to be set in motion before the phenomena of a current of electricity are produced. A battery is an electron pump, and when its terminals are joined by a wire it forces the electrons in the wire round and round the closed path or circuit formed by the battery and wire, this electron stream passing, in the wire, from the negative battery terminal to the positive one. Since, however, the idea of a current of electricity flowing from a so-called positively charged body to a so-called negatively charged one has become ingrained in electrical matters, it continues to be used, with the tacit reservation that the "electronic current"—which is probably the only real "current" concerned—flows in the opposite direction.

Digitized by Google

We have stated above that a stream of electrons is continually shot off from the glowing filament of a valve. If the positive pole of a battery B_2 (Fig. 12), the high tension battery, be joined to the anode, and its negative terminal to the filament, a complete circuit round which electrons can flow will be formed, and, since the battery provides the necessary driving force, a current will accordingly be set up. The electrons shot off from the glowing filament are attracted across to the positive anode, and complete their circuit through the battery and the connecting wires. The actual electron stream flows round this circuit in the direction from the negative pole to the positive pole of the battery B_2 (clock-wise in Fig. 12), but, as explained above, this electron stream is described as a "current" in the reverse direction, that is, in the direction shown by the arrows in Fig. 12.

Thus the space between the anode and the filament of a valve can be considered as a conductor, completing the circuit of the high tension battery, and allowing a current to flow. But it is different from an ordinary conductor, because current can only flow across it in one direction, from anode to filament (using "current" in its old sense). If the high tension battery be reversed, so as to make the filament positive and the anode negative, then the electrons, as fast as they are shot out from the filament, will be attracted back to it again instead of passing across to the anode, and so no current can flow.

With a fixed value for the voltage of the high tension battery, and with the filament kept at a steady temperature, it will be clear that, assuming no disturbing cause to come into action, the anode current will remain steady. But across the valve, between the filament and the anode, lies the grid, and the electrons, in their passage along the valve, have consequently to pass through its meshes. It is evident that the electrical state of the grid will have an effect on the magnitude of the electron stream which reaches the anode. If the grid be made negative, then, since the electrons are also negative, and similarly charged bodies repel one another, the grid will tend to stop the electrons as they flow towards it from the filament in response to the attraction of the positive anode, and to repel them back towards the filament. When the grid is made very negative none of the electrons will manage to get past it at all, and the anode current will fall to zero. As the grid is gradually made less and less negative more and more electrons will succeed in getting past it and reaching the anode, and so the anode current will rise.

Certain other actions take place inside the valve, unless the interior is absolutely free from traces of air or other gas. A molecule of a gas is composed of a positive nucleus surrounded by a certain number of electrons. In the ordinary condition the positive and negative charges in the molecule are equal, and therefore balance one another, and so the molecule is apparently uncharged. When an electron moving with high velocity collides with a gas molcule, the shock may cause an electron to be detached from the molecule, leaving the latter with an excess of positive charge. The molecules from which electrons have been removed are known as "ions," and the process is called "ionisation." Ionisation will begin in a valve in which the necessary trace of residual gas exists as soon as the velocity with which the electrons move is sufficiently great, and this velocity will evidently depend on the amount of retardation or otherwise which the electrons experience from the effect of the potential of the grid.

When ionisation begins the number of electrons in the valve will be greatly increased, for not only are those which are released from the molecules in the collisions added to the general stream passing towards the anode, but the positively charged ions will be attracted to the filament, to which the negative terminal of the high tension battery is connected, and they may strike the filament with sufficient force to raise its temperature and so cause a greater number of electrons to be set free.

For the valve of which the characteristic curve is shown in Fig. 13, this increase in the anode current begins when the potential of the grid is about half a volt below that of the negative end of the filament. The maximum rate of increase of the anode current corresponds to a positive grid potential of about a quarter of a volt.

When the grid is made positive, however, it begins to attract the negatively charged electrons to itself, and so the number which succeed in getting through and contribuitng to the anode current is diminished. At first the increase in electrons due to ionisation is greater than the decrease due to the attraction of the grid, and so the anode current continues to increase. But as the grid is made more and more positive the number of electrons which it attracts gets greater and greater, and at length the rate of increase of the anode current begins to diminish. For the curve shown in Fig. 13 this occurs when the positive grid potential reaches about one volt. The rate of increase becomes less and less as the grid potential becomes greater, and consequently the curve showing

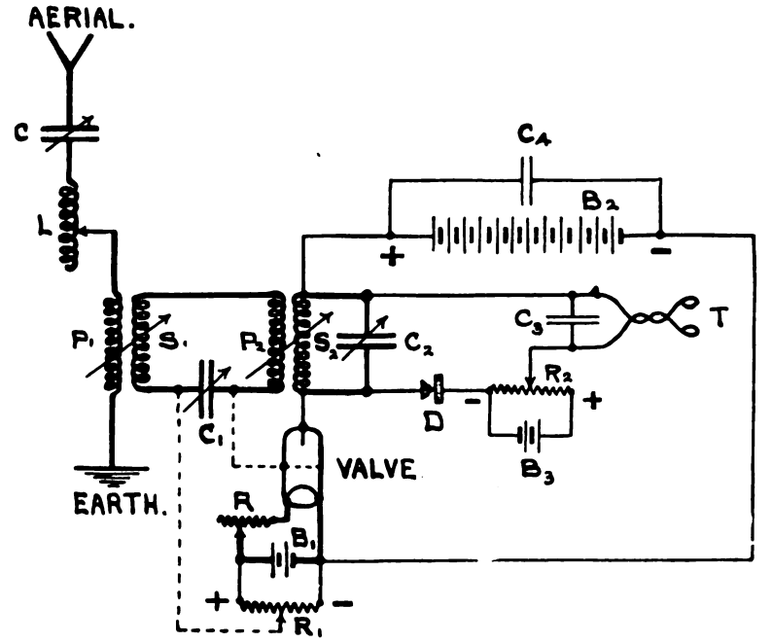

FIG. 14.—CONNEXIONS OF RECEIVING SET, USING HIGH-FREQUENCY AMPLIFIER AND CRYSTAL DETECTOR.

the anode current bends over and at length becomes horizontal. If the grid potential were made still more positive the drain of electrons would be so great that the anode current would begin to decrease.

Applications of Valves in Wireless Telegraphy.

We are now in a position to understand how these thermoelectric valves are employed in wireless telegraphy. They can be used for several different purposes. In the first case a valve can be associated with a crystal detector circuit, such as that shown in Fig. 10, in such a manner as to increase the amplitude of the oscillations set up in the closed oscillatory circuit when a train of electric waves passes the aerial. Thus louder sounds are produced in the telephones. This is known as "high frequency amplification." As far as the part of the circuit containing the crystal detector and telephones is concerned, the effect is exactly the same as if the power of the transmitting station from which the signals are being received had been increased.

Valves may also be used to take the place of a crystal detector for rectifying the oscillations and so producing sounds in the receiving telephones; for magnifying the sounds in the telephones; for receiving continuous waves; and for generating oscillations at transmitting stations.

These various applications will be dealt with in order.

High Frequency Amplification.

Fig. 14 shows the connections of a receiving circuit arranged for high frequency amplification and crystal detector rectification.

Digitized by Google

Between the open and closed oscillatory circuits of Fig. 10 is inserted a third oscillatory circuit S_1 P_2 C_1, known as the "intermediate circuit," but the arrangement is exactly the same in principle as that shown in Fig. 10.

In series with the aerial is joined the aerial tuning condenser C, the aerial tuning inductance L, and the primary coil P_1 of an oscillation transformer. The secondary coil S_1 of this transformer is joined in series with a variable condenser C_1 and the primary coil P_2 of a second oscillation transformer, so forming the intermediate oscillatory circuit. The secondary coil S_2 of this second transformer is joined in series with a variable condenser C_2, and thus a second closed oscillatory circuit is formed. Across the condenser in this circuit is joined the crystal detector, potentiometer and telephones, exactly as in Fig. 10.

The aerial circuit and the two closed oscillatory circuits are adjusted so that their natural frequencies are the same and are equal to that of the incoming waves.

The coupling between the primary and secondary coils of the two oscillation transformers is adjustable. The oscillations set up in the aerial by passing electric waves act on the intermediate circuit by means of the transformer P_1 S_1, and set it into oscillation. The oscillations in the intermediate circuit set up oscillations in the circuit S_2 C_2 by means of the transformer P_2 S_2. Across the condenser C_2 is joined the crystal detector D, the potentiometer R_2 with battery B_3, and the telephones T with telephone condenser C_3. The oscillations in the circuit S_2 C_2 are rectified by the crystal detector and affect the telephones in the ordinary manner.

The advantage of the intermediate circuit is that by its use "jamming" by signals of wave lengths other than that which it is desired to receive is reduced, especially if the coupling between the two oscillation transformers be made small. The aerial circuit may be forced into oscillation by these unwanted signals, but since the frequency of the oscillations so set up is different from that to which the circuits are tuned, the impulses on the intermediate circuit through the oscillation transformer will not occur at the proper intervals to set up strong oscillations in that circuit.

Any weak oscillation of the unwanted frequency which may be set up in the intermediate circuit will for the same reason have great difficulty in producing oscillations in the final oscillatory circuit, and so the effect on the telephones of the unwanted signals will be very small indeed.

The arrangement described so far constitutes a complete receiving set, using a crystal detector. The introduction of the valve does not affect the principle of this arrangement in the least, its purpose, as mentioned above, being only to increase the amplitude of the oscillations in the circuit S_2 C_2.

(To be continued.)

SELECT COMMITTEE ON THE TELEPHONE SERVICE.

RESUME OF EVIDENCE (*continued*).

Mr. W. H. ALLEN, Controller of the Post Office Stores Dept. was examined on *June* 15. He said that more than half of his time was devoted to telephones, and did not think the appointment of a separate controller for telephones would be economical. He described how stores were purchased and tenders obtained, how classified, and how repairs were carried out. £500,000 worth of apparatus was dealt with in the factories each year. He explained the relations of his department with the Stationery Office, and gave evidence on local sales of plant and on distribution of the telephone directory.

The RT. HON. E. G. PRETYMAN, M.P., gave evidence on *June* 22 on behalf of the Land Union. He stated what he paid for his telephone at Ipswich, Felixstowe and in Lincolnshire, and what he had paid in Norway 20 years ago. He thought that free scope should be given to local bodies in rural areas to provide their own systems, and that rural systems should be cheaper than large town systems.

Mr. A. V. ALEXANDER, representing the Co-Operative Societies, was heard on *June* 27. He agreed that the service should be self-supporting, and said that as regards war bonuses the Society would never stand for any attack upon wages to Civil Servants. He thought, however, that the increased charges would reduce the use of the service. The Society were in favour of the message rate system, but thought a larger discount than that proposed should be given to large users.

On *June* 29 Sir CHAS. OWENS, a director of the L. & S.W.R., gave evidence on behalf of the London Telephone Advisory Committee. He said that prices had come down since the Departmental Committee reported, and that the new rates were based on figures which had become obsolete. He compared the arrangement of the Engineer-in-Chief department with that of a railway company's engineering department, and suggested that there was duplication of clerical work in the P.O. He compared operator's wages with those paid to women by private firms, and complained of lack of co-operation and co-ordination between the spending department and the selling department. As regards the flat rate he said that the P.O. was to blame for overloaded lines, and he thought the fact that the flat rate had not been abolished earlier was a proof that the administration was bad. He suggested larger rebates on the message rates. Sir Charles came in for a good deal of heckling by the members of the Committee with reference to railway service, and delays to calls were compared with the overcrowding of carriages, which he appeared to justify. The table of wages which he produced was also much criticised.

Sir ISAAC CONNELL, Scottish Chamber of Agriculture, gave evidence on *July* 4. He thought that the telephone service should be worked on business lines, that the State should economise and bear the loss while prices are high. The present rentals, he said, were prohibitive for farmers, and rural party lines were not suitable for Scottish farmers. He thought the extra mileage rate should be reduced from £10 a mile to £5.

Lt.-Col. W. J. O'MEARA gave evidence on *July* 11 on behalf of the London Telephone Advisory Committee. He was Engineer-in-Chief of the Post Office 1907-1913. He thought that the telegraphs and telephones should be separated from the Post and Savings Bank and that the work should be decentralised. He complained that in his opinion the Engineer-in-Chief was subordinate to the staff of the Secretary's office. He gave particulars of the administrations in Italy, Germany, and Sweden, and suggested a direction-general for telegraphs and telephones and a direction general for posts, both under the same minister. He thought the traffic department should be under the engineer-in-chief, who should be the principal man under the minister on the telegraph side.

Mr. ALEX. MCEWEN (Highlands Reconstruction Association) was the next witness (*July* 13). He complained of the cost of proposed guaranteed trunk lines into the Highland districts, and of the proposed telephone rental charges. He gave comparisons of rates for rural districts in Great Britain, Switzerland, Sweden, and Norway. The Highlands were a poor district and wanted help, but he thought the service would eventually pay.

UNVEILING OF THE CENTRAL TELEGRAPH OFFICE WAR MEMORIAL.

AN impressive ceremony took place on Sunday, July 17, in front of the G.P.O. West before a large gathering when the memorial tablet inscribed with the names of those members of the C.T.O. who had fallen in the great war was unveiled by the Postmaster-General. The subscription to the Memorial had exceeded £1,300, and with the major part of this sum a bed was founded and endowed in St. Bartholomew's Hospital, of which Mr. A. W. Edwards, Deputy Controller of the C.T.O. and chairman of the War Memorial Committee was elected a Life Governor.

The band of the Post Office Rifles, which was in attendance, played Sullivan's In Memoriam, and after Mr. A. W. Watts had read the names of the fallen, the St. Martin's Glee Singers gave a rendering of Mendelssohn's "For ever Blessed." Mr. Edwards then presented photographs of the receipt for £1,000 and of the bed at St. Bartholomew's Hospital to the Postmaster-General and requested him to unveil the Memorial.

The Postmaster-General (the Right Hon. F. G. Kellaway) having done so, read a letter from Lord Stamfordham, the King's Secretary, expressing His Majesty's thanks for the Souvenir of the occasion which had been sent to him, and his recognition of the work done by the Telegraph Service. Mr. Kellaway remarked that Wellington commanded about 30,000 British troops at Waterloo, and that the British Post Office had sent three times that number of men to the late war, of whom 9,000 had laid down their lives. It was a record of which the Post Office might be proud. Divided as were these men's interests during life, their unity was so great during the war that they were prepared to give their lives for it. To be worthy of them and to do the things that matters, we must be united in our lives.

Following on the hymn "O God, our help in Ages past." the Bishop of London was asked by the Controller, Mr. John Lee, to dedicate the Memorial. The Bishop, after reading the dedicatory prayers, referred to his connexion with the P.O. volunteers. He pleaded for peace at home, and begged all to work with determination so as to be able to show something worthy of the blood which was shed in defence of the country.

After another quartette by the glee singers, the "Last Post" and "The Reveille" were given by Mr. W. W. Hodges and Corporal W. G. Veazey. Then after a few minutes' silence Mr. H. S. Jordan and Miss Russell thanked the Bishop on behalf of the War Memorial Committee, and the proceedings terminated with "Land of Hope and Glory" by the band. During the ceremony, foreign offices were requested to suspend work with the C.T.O. The following messages were received in reply:—

Ns agreons volontairement votre attente et sommes touches par la pensee sympathique d'eriger un monument pr les collegues tombes qui ont ete aussi nos collegues.—(*Rome.*)

Digitized by Google

D'accord pour la suspension du sce 3.30 a 4 heures. Nous nous associons bien sincerement a la ceremonie qui commemore la memorie de nos collegues anglais tombes pour la defense droit de la justice et de l'honneur.—(*Bruxelles.*)

Entendu pour l'interruption a partir de 3 h. 30 nous sommes de coeur avec vous dans cette circonstance.—(*Paris.*)

The Hague and Hamburg also agreed.

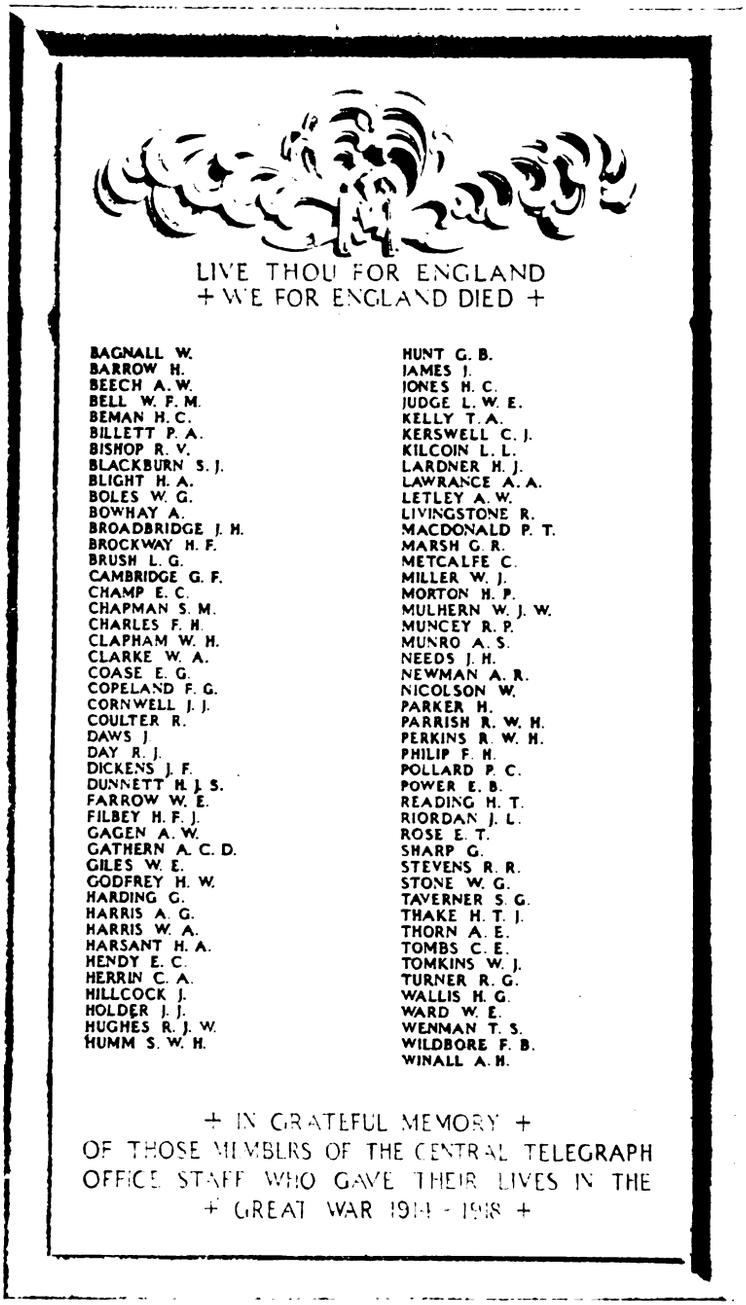

Photo by ALEXANDER CORBETT, 48, *Baker Street, W.*

LONDON TELEPHONE SERVICE NOTES.

Miss A. A. Heap, I.S.O.

MISS HEAP has still a few more days with us at the time of writing these notes, but she will have vacated the official chair before they are circulated, and they must needs go to press before the reception and presentation to her takes place. An account of the function will, therefore, necessarily be delayed until the September issue.

* * *

Friday, June 24, heard another echo of the bazaar. It was the anniversary of the opening of the South London Hospital for Women, and H.H. the Princess Helena Victoria, who attended the fete held to celebrate the event, received purses. A small sum, £12, still remained from the proceeds of the bazaar, and Miss Channer (Sidcup) and Miss Wheatley, City Exchange, had each the honour of presenting to her Highness a purse of £6. The full sum raised by the bazaar and by additional subscriptions has reached the grand total of £2,512.

The Imperial Swimming Club (Trunk Exchange).

The club are holding their Annual Swimming Gala at the Holborn Baths on Sept. 14. A 60-yards handicap, open to all ladies' departments of the Service, will be held.

Will Club Secretaries please forward names and times of intending competitors to the Secretary, Miss Hodder, Trunk Exchange, G.P.O. South, E.C.4, not later than Aug. 15. Entrance fee, 1*s.* 6*d.*

Further Light on the Wrong Number Trouble.

This time it is the *London Mercury* which has been unravelling the mysteries of the wrong number trouble, and we are extremely grateful to learn from so respected a source that there is foundation for our apprehension that some at least of the wrong number tales are "fishy" ones. The July issue includes a poem by Geoffrey Dearmer, of which the following is an extract :—

> "Where crabs with eyes set squinting in their shells with sidelong crawl
> Are scudding; where the baby dabs with squashed flat faces sprawl;
> Where the lurking lobster spawns and a hueless host of prawns
> Where anemones like rubies gem the rough and rocky wall,
> And swimming from a narrow—'Are you Hammersmith or Harrow?
> Yes, I want you. Wait a moment, two-nine-seven London Wall.
> Five? Sorry you've been troubled: two-five-seven London Wall.'"

Contract Branch.

The Contract Branch has during the past month lost one of its well known figures in the person of Mr. William Logan Rae, who retired on July 3, having attained the age of 60 years on that date. He entered the service of the National Telephone Company on April 11, 1905, and was appointed Divisional Contract Agent of the North-East Division of London in September, 1910. The North-East Office was one of the two Contract Offices in London which were closed down for reasons of economy in the early days of the war, and Mr. Rae then acted as a third class clerk in the Accounts Branch, subsequently being transferred to the Headquarters Section of the Contract Branch. His health has been far from good for some time past, and all who know him will join in wishing that as a consequence of his rest from official duties he may be completely restored to health.

* * *

How greatly simplified the Revision of Rates work would have been if all subscribers had adopted the same attitude as the writer of the following letter :—

"We beg to acknowledge receipt of your letter of the 28th instant. In these matters the public are entirely in the hands of a Government Department. You will remember when you were a boy reading the fable of the lamb and the wolf. Whatever we do in the guise of the lamb we are quite satisfied that you will devour us some day in the future.

"We, therefore, academically agree to all your terms and everything you suggest, because we are entirely helpless."

Langham Choral Society.

Rehearsals re-commence on Sept. 13 and will continue weekly on Tuesdays at 6.30 p.m. at the Rangers' Hall, Tottenham Court Road, W.C.1.

The first concert of the season will take place at the Queen's Hall on Armistice Day, when the programme will include Beethoven's Mass in C and Elgar's "Banner of St. George."

Vacancies still exist for tenors and basses. Applications for membership should be addressed to the Hon. Secretary, Miss W. M. Nurse, 11/12, Norwich Street, E.C.4.

Minus and Plus.

With the provision of a new exchange located at the Orpington Post Office to serve the Cray area, the late Cray subscribers pass from the London to the Brighton District and are re-christened Orpington. The Cray Exchange had 87 subscribers, and on that basis was among the four smallest exchanges in the London Telephone area. It had been in use for 17½ years and was of the magneto type. The new installation is C.B. signalling.

The new Toll Exchange in Norwich Street, Fetter Lane, is rapidly nearing completion, and with the new exchanges, Grosvenor and Minories, will probably be opened at no great distant date.

The Belgrave Social and Athletic Club.

The members of the above club and their friends spent an enjoyable day at Tunbridge Wells on June 19.

We started from the Manor House at 10.20 a.m., and, after stopping at Dalston to pick up the remainder of the party we soon left the City behind and enjoyed a splendid view of the surrounding country. We arrived at Tunbridge Wells at 1.40 p.m. where an excellent luncheon was served at the Swan Hotel. This hotel proved doubly interesting, as hanging in the stairway were several very clever cartoons, depicting the transfer of the telephone system in Tunbridge Wells to that of the G.P.O. in 1912.

During the afternoon several of the party walked to Happy Valley and "Toad Rock," armed with cameras, but, owing to the rather bad light, the efforts of the majority were not very satisfactory. After tea, which took place just after 5 o'clock, a rag cat was raffled among the party and realised £1 1*s.*, which has been sent as a donation to St. Dunstan's Hostel. Everyone thoroughly enjoyed themselves, including the drivers and conductors, and it is hoped by all to have a similar trip in the near future.

SUNSPOTS AND MAGNETIC STORMS.

By ARTHUR E. COTTERELL.

THE magnetic storm of May 14 and 15 last not only affected the needles at the observatories and caused considerable interference on telegraph systems throughout the world, but afforded us another reminder of an unsolved problem of nature. Although we are well acquainted with effects, our knowledge of the causes is very far from being established.

It is true that several plausible theories have been advanced but terrestrial magnetism is surrounded by so much that is complex, contradictory, or elusive, that none of them can at present be regarded as conclusive.

In the course of my study of the subject there are certain points which have particularly impressed me as adding to the complexities.

It is generally accepted that sunspots pass through cycles in which their maxima or minima respectively are attained on an average of about 11.1 years and that magnetic disturbances are closely in accord therewith; magnetic storms of magnitude being usually coincident with sunspot maxima. Graphs of various observatory records certainly support this theory.

In my estimation, however, the most important storms are not merely those which bring about violent agitations of the needles but those which also induce "earth currents" so strong and variable as seriously to interfere with single wire telegraph circuits, the extremities of which are connected with the earth. Now, although such telegraph circuits are frequently affected by minor "earth currents" the great magnetic storms to which I have alluded occur at very irregular periods and curiously enough do not coincide with sunspot maxima or minima, as the following table of some of the greatest storms will show:—

Magnetic storms affecting telegraphs.	*Sunspots.*	
	Maxima.	*Minima.*
Sept. 1, 1859	1860.1	1856.0
Aug. 3, 1872	1870.6	1867.2
Nov. 17, 1882	1883.9	1878.9
Feb. 14, 1892	1894.1	1889.6
Oct. 31, 1903	1906.1	1901.7
Sept. 25, 1909	1917.7	1913.1
Aug. 11, 1919		
May 15, 1921		

It is not suggested that there is no connexion between spots and storms; the recorded evidence is overwhelming, and on each of the occasions mentioned there was a huge spot or group of spots. The point which I desire to emphasise is that none of these great storms during the last 62 years have been coincident with a maximum spot phase if we except the storm of 1859, which did nearly coincide.

As the average interval between sunspot maxima shewn in the above table is 11.5 years and minima 11.4 years it should be stated that the 11.1 years average is based on records taken over a much longer range of years.

The most tenable theory as to the connexion between sunspots and magnetic storms appears to be that which was, I think, first advanced by Mr. Maunder, in which it was suggested that streams of electrified particles are ejected from the spotted region of the sun and that these affect the earth's magnetism and set up or start terrestrial currents if such a stream happens to be so directed as to hit the earth's atmosphere. Whilst very largely accepting this view, I am constrained to indicate certain circumstances which present some difficulties when considered in conjunction with the generally accepted graphs which illustrate the connexion between magnetic storms and sunspot maxima. It is well known that coronal streamers are comparatively short all over the sun at periods of sunspot maxima and that at periods of sunspot minima there are always long equatorial streamers extending probably beyond earth-sun distance, and that from their direction approximating to the ecliptic such streamers are likely to reach the earth. Examination of them by the spectro-heliograph has revealed their electric or electrified nature. It would, therefore, seem to be curious that magnetic storms should occur when these electric streamers are short, as at times of sunspot maxima rather than on occasions of sunspot minima when the streamers are long. No doubt much may depend on the precise direction of any particular stream, but the conditions to which I have alluded seem to illustrate some of the complexities and contradictions which surround any inquiry into this interesting but elusive subject.

In considering the incidence of sunspots it is a natural though to question the possible effects of combinations of the planets. Some years ago I made rough computations of their relative positions at various dates of magnetic storm with a view to ascertaining whether the configuration was such as might warrant the assumption that the combined gravitational pull of several in a given direction might be a key to the secret, either as causing the spots or directing the electrified streams. I have recently gone over my figures and added similar details as to later storms.

In a few instances the configurations seem to be suggestive but in others the positions of the planets were such as rather to dispel the thought. I understand that Prof. E. W. Brown some years ago investigated the planetary positions at certain times of sunspot maxima, but although obtaining some extremely interesting results, missed establishing an acceptable theory owing to certain occasional discrepancies.

If I may venture to tread on speculative ground I would suggest that there is still one field within the Solar system which, so far as I know, has not been explored in this connexion, and which in the present state of our knowledge cannot yet be fully investigated. I refer to the minor planets whose orbits lie between those of Mars and Jupiter, not as a sole cause, but as a possible contributory one.

I quite realise how comparatively small they are and am aware of the views held by eminent astronomers as to their probable aggregate mass. Their views, however, seem to vary considerably and can hardly be deemed to be conclusive at the present stage when we do not know how many asteroids there are. In one respect we have definite information, that is in regard to the periodic times of a very large number of them which we know vary between some three and nine years.

It follows that they must be continually changing their position in relation to one another just as runners in a race of several laps change their groupings, from which we may infer that at times they are scattered in the belt of their orbits whilst at others they may form groups which may conform more or less with the celestial longitude of some of the eight principal planets.

It has naturally happened in the past that special consideration should be given to Jupiter on account of his giant size, the close approximation of his orbital plane to the ecliptic, and not least of all to his period of 11.86 years so closely approximating to the 11.1 years average of sunspot maxima. On the other hand it was easy to discard Jupiter, as not only is there a difference in the two periods of .76 of a year but there would be cumulative differences with succeeding cycles, although after many years they would come into phase again to be followed with a repetition of the divergencies. Another reason for discarding Jupiter arose from the fact that his time of reaching perihelion can only rarely coincide with sunspot maxima.

Had there been a planet whose periodic time was about 5.74 years its synodic period with Jupiter would have been about 11.1 years.

Seeing that a large number of the known minor planets have periodic times ranging about 5 or 6 years it would not seem unreasonable to speculate as to the possibility that they may be a contributory cause of sunspots in combination with Jupiter.

Recently I attempted a preliminary investigation as to the motions and positions of the first 280 minor planets. The changes of groupings was interesting but not such as I could consider strongly suggestive. As I have already said, however, any such theory cannot be adequately probed until we are possessed with a fuller knowledge as to the many thousands, perhaps millions, of asteroids which it is thought may exist.

TELEGRAPHIC MEMORABILIA.

THE *Cable Room Monthly* of June anent the retirement of our esteemed friend, Mr. C. F. Moody, reminds us of one of the most interesting of the many reminiscences of our colleague. It was on Dec. 10, 1877, when the receipt of the news of the fall of Plevna came trickling through to London by Morse-printer on the direct London-Vienna wire. Archibald Forbes, the famous newspaper correspondent, "rode some 50 miles to a small telegraph station and got his message in first to the Austrian capital. The *Daily News*, to whom the telegram was addressed, was advised that the message was being received on that momentous Sunday evening and made preparations for the 'scoop.' The last pages were rushed to their offices sheet by sheet in a cab."

I find I am expected, by some of my particular friends, to write something on the Advisory Committee which is at present sitting on the Post Office—metaphorically, of course! While anxious to oblige it is very questionable whether I shall give voice to exactly the sentiments which those particular friends would have expressed for the simple reason that, feeling unbounded confidence in our organisation, without esteeming it faultless, there does not appear to be room for any qualms respecting the final result of any enquiry into our ways and method. To write that much does not infer that there is no room for improvement in method, in apparatus, or in personnel. One can find flaws in the organisation and material and goods, yes, and even in the personnel of some of the best organised and best advertised emporia. That at least has been the sad experience of the writer, sad but comforting in that one recognises the human touch in its very fallibility. One has heard of private railway companies whose engineers have designed engines too heavy to travel over certain bridges of their own system, others whose funnels would not pass under arches of their own building. One has heard of shipbuilders whose vessels have been failures, and commercial men whose business methods have brought the whole fabric of their design crashing about their ears with untold misery for thousands in its train. Behind the history of the Post Office and its administration there is at least the unique record of much unselfish thought and labour for the community, and not a single error which has ruined a life or broken a heart. Our one great difficulty has been and will be for many years yet, to obtain that sympathetic understanding of the difficulties and intricacies of the technical side of our crafts. It is one thing to drop a letter lightly into the pillar-box, to hurriedly scribble a telegram and throw it across the counter of the nearest Post Office, or to call up the doctor, the police, the fire-brigade or the theatre on the 'phone, and quite another matter to appreciate to the full the personal service rendered, the complicated organisation demanded, and the skill required to give the most satisfactory results for the few pence at which such services may be purchased.

Post Office administrators would have a much easier task if, once and for all, it were definitely laid down that it was to be run either on commercial or philanthropic lines, but the pendulum of criticism swings first in one direction and then in the other. No private organisation has ever been requested to adopt both methods, or even to work them alternately.

The C.T.O. Amateur Gardening Association held their Fruit, Flower and Vegetable Exhibition in an out-of-the-way corner of the building kindly lent for the purpose on July 6. How the exhibitors managed to produce so high a standard of excellence in each of these departments is their own secret. There was, however, a complete absence of those phenomenally sized tubers which the normal season produces and which are apparently the particular pride of the prize grower.

It is regretted that room cannot be found for the complete list of prize winners, space available only permitting the names of "Firsts" in the various classes of the following:—Potatoes: Mr. P. Hutchins, Mr. G. H. Parker. Carrots: Mr. F. S. Parker, Mr. C. W. Ledger, Mr. C. Land. Beans: Mr. C. Young. Edible Peas, Onions, Beetroot, Shallots, Rhubarb, Violas, Sweet Peas: Mr. F. S. Parker first in each of these seven classes. Turnips: Mr. C. Young. Bush Fruit: Mr. T. H. Wright. Roses (two classes), Violas, Spray: Mr. E. F. Bing. Rambler: Mr. E. Bothwell. Sweet Peas: Mr. H. Lang. Violas, Cut Hardy Flowers, Antirrhinums, Annuals: Mr. W. P. Barry first in each of four classes. Cut Flowers: Mr. C. W. Ledger. Biennials: Mr. E. Hill. There was a special class for Novices, apparently those who had never before exhibited in the following:—Potatoes: Mr. W. A. Fisk. Onions: Mr. J. Pratt. One Rose: Mr. W. P. Barry. Sweet Peas: Mr. F. S. Parker. Violas: Mr. W. P. Barry. The first prizes for the arrangement of cut flowers went to Miss M. J. Clarke and Miss L. F. Ransom (novices). Special congratulations are due to Mr. F. S. Parker for his record of eight firsts, three seconds, one third. The cut flowers were despatched to our friends and neighbours, the patients of St. Bartholomew's Hospital, from whom a grateful acknowledgment was duly received.

Advances in the direction of improved selectivity for Wireless Telephony may be judged by the following experiment which the *Telegraph and Telephone Age* records as having been described by Mr. E. F. W. Alexanderson before the Institute of Radio Engineers at New York. A trial installation was erected three miles from the New Brunswick station whose wave length is said to be 13,600 metres. Despite this close proximity, signals from Carnarvon, Wales, were distinctly and clearly received at the experimental station, although the wave-length of the Welsh station is 14,200 metres. The New Brunswick signals, despite their intensity and small wave-length difference, were practically obliterated by the special methods described by the lecturer.

A correspondent who is always interesting sends a number of newspaper cuttings which he encloses to prove that there is "some reference to telegraphy in almost every paragraph one reads nowadays." Whether our friend has been particularly lucky in the days he has chosen from which to prove this bold assertion, I am afraid my own lack of observation is unable to verify. Truth, however, bids me place on record that on four consecutive days in a recent month the following subjects were either heavily head-lined or mentioned with some degree of prominence in a leading London daily:—"The Admiralty (Signalling) Flag Book," "Hundreds of Telegraph Wires cut in England," "Wireless calls for help. Ship strikes iceberg," "Submarine Cable Telegraphy (Oscillatory Circuit Signal Conditions)," "Warning electric Signals for Vessels approaching land, the submarine cable method," "Wireless Tests by R36," "Eastern Telegraph Company's dividend," &c., &c. It is an interesting list and only intensifies what many of us do not perhaps fully realise, how much in modern life depends and centres round the art of signalling in one word *our* craft!

The recent visit of representatives from the Celestial Empire to the C.T.O. has, we trust, proved of no small utility to our Chinese colleagues. On the other hand, thanks to the courtesy of these same representatives, we have gained that ever interesting experience of a peep into other lands as well as that generally speaking chastening experience of seeing ourselves as others see us.

We learnt of some of the difficulties experienced by the Chinese in applying their language to a telegraphic system. Burdened with a written tongue which necessitates the use of some thousand or so of signs to represent its various meanings when telegraphing it becomes necessary to signal each one of these by a series of numbers. Thus telegraphy in Chinese vernacular always means an uninteresting text comprised solely of figures. When the sender of a telegram hands his message in at a Chinese Post Office, having first written or rather painted it on the form with a brush, it is coded into groups of figures. These are signalled through to their destination where, should the receiver require it, the telegram is decoded, at an extra cost of 10 per cent. As a point of interest I was assured that there were certain Chinese counter clerks who could code or decode no less than three thousand of these groups without referring to the key. Whether legend or not I cannot tell, but it was also stated that an American had invented a type-writer capable of printing two to three thousand characters. It was not a portable machine, as it occupied about the same space as an ordinary upright piano!

The daily output of an office of the size of Pekin is not more than twelve to fifteen hundred telegrams. Each Chinese telegraph office retains its forms for twelve months. My informant stated that there was a movement in commercial China to utilise the English language entirely for commercial purposes, and with this end in view the Pekin University had conceived the idea of compiling a special Anglo-Saxon commercial vocabulary for general use which would prove of special utility in telegraphing and cabling. One can understand that so cumbersome a system of communication had proved a heavy handicap in international trading.

It struck our visitor as something humorous that we should lend staff from one division to the other. In Chinese offices the same superintendent always controls the same staff and only in the event of one of the latter desiring transfer to another "division" or "brigade" on the grounds of disagreement, or for some other cause, is a change ever permitted or even desired.

The following appointments are announced in connexion with the C.T.O. Foreign Telegraph Department. To be Assistant Superintendents, Messrs. Page, Poffley and Pratt. To be overseers: W. Annible, C. J. W. Barrett, Beaumont, Classey, Cumber, Fursman, Roebuck, Upson, and H. A. Webb. To one and all the sincerest congratulations from past and present colleagues.

J. J. T.

The above is a picture of the Bradford Telephonists' Hockey Club. The sender assures us that the members are even more excellent as telephonists than hockey players.

CORRESPONDENCE.

CONTRACT BRANCH NOTES.

TO THE EDITOR OF THE "TELEGRAPH AND TELEPHONE JOURNAL."

DEAR SIR,—It was with pleasurable feelings that the writer commenced to read the article under the above heading on page 161 of the T. & T. JOURNAL for July, 1921.

My pleasure was, however, soon turned to dismay when, upon reading the second paragraph one learned that "the only exchange line cases dealt with by that branch are those where the subscriber has decided to allow his agreement to cease, &c.," and one said to oneself, "surely this was never written by a contract man"—but there it is, and one must suppose that one has been dreaming during the past eight months and that instead of being in the midst of a whirlwind of hundreds of various matters concerning preliminary work, issuing notices, following up with agreements, then reminders, telephone calls, and finally disconnexion forms one has only simply been dealing with cases "where the subscriber has decided to allow his agreement to cease, &c."

Reading on, one becomes more interested, and nods agreement at the results regarding the new private wire rates.

Then behold the sequel; the article relates to London only (lucky devils) —and not to the whole of the country. This fact is, one hesitates to say deliberately held back, but certainly very modestly kept from the reader until the last paragraph,* and in almost the last word, for who but London could refer to "long circuit to the Provinces."

Most contract managers will be inclined to commiserate with their brethren of the London Contract Branch because of that which they (L.C.B.) have missed, and having successfully accomplished a task which at times seemed overwhelming, one sticks out one's chest and with pride tells you that he would not have missed it for anything.

Thus, dear old London, we of the Provincial Contract Sections, can perhaps be permitted to blow our humble trumpets and say, whenever memories of the Revision of Rates are revived, "well, *we* did it *all*."

Please don't think, ye Londoners, that this letter is written in a boastful mood, for your difficulties are appreciated, but it is desired to correct an impression which the uninitiated would form were the fact that the article refers to London only not given publicity.

ROBT. P. LOWE,
Contract Manager.

Telephones, Norwich, July 9, 1921.

* The Editor must be held responsible for this. The Contract Branch Notes were sent in by the writer of the London Telephone Notes along with his other paragraphs, but the Editor thought them sufficiently interesting to require a separate heading. There was, therefore, obviously no idea on the writer's part that he was referring to any district but London, and it was unnecessary for him to say so specifically.

As one of the writers of the Contract Branch Notes which appeared in the July issue of the JOURNAL, I have been favoured with a sight of Mr. Lowe's letter. One has always regarded the city of Norwich (for obvious reasons) as "hot stuff" and, therefore, one has confidence that the Contract Branch of that city will have lived up to its reputation. It should, however, perhaps be mentioned that the total number of stations in London is well over 320,000. In London, too, it must be remembered that there are four separate Contract Offices none of which is housed in the same building as the Accounts Branch, and, therefore, it was far more economical for the work in connexion with exchange lines to be dealt with by a special staff in the Accounts Branch rather than that the very heavy work should have been undertaken of splitting up the rental ledgers into the four sections concerned. It is interesting, too, to note that over 11,000 Exchange cases were dealt with by the Contract Branch in London in connexion with the revision of rates work and these cases, so dealt with in London, are, as pointed out in the second paragraph of the July notes only the difficult ones, and therefore, London's backwash is probably of greater volume than Norwich's full flood.

W. GLENNY.

July 13, 1921.

CIVIL SERVICE SPORT.

AN OPEN LETTER TO ALL CIVIL SERVANTS.

Ladies and Gentlemen,—It should be evident to all members of the Civil Service that the time has now come when a strong effort should be made towards the establishment of Civil Service Sport upon an adequate organisational basis. At the present time there is no body in existence which can be said to represent the Civil Service in sport. There has long been in existence, it is true, the Civil Service Athletic Association, which has just held its fifty-fourth Annual Meeting at Stamford Bridge. But the scope of this Association is limited solely to athletics and, even so, its organisation is by no means as perfect as might be desired. Neither the Civil Service Association Football Club nor the Civil Service Rugby Football Club can be termed representative, because, so far as our inquiries lead us, no effectual effort is made from year to year to attract the best talent the Service possesses to these clubs. During the football season just ended an effort was made to arrange a match between the Civil Service Football Club and a team representative of the Civil Service Football League. The effort proved unsuccessful largely, we believe, because of lack of energetic support for the proposal by the League teams. As for the Civil Service Cricket Club, the less said about it, as being representative, the better. The Civil Service Amateur Swimming Association may be said to be truly representative, and it is to be hoped that other sections of sport within the Service will speedily perfect their organisations to the same extent as has been done by the swimmers. Even here, however, we find the handbook for the year 1921 "Roneo-ed" and not printed; and several championships are still without trophies (back-stroke, diving, life-saving and various team and ladies' championships).

Our object in drawing attention to these matters is to secure the establishment in the very near future, of a Civil Service Amateur Sports Association which shall truly represent all branches of Civil Service Sport (duly affiliated to such organisations as the A.A.A., L.F.A., R.L.S.S., S.C.A.S.A., R.W.A., L.R.C., and N.C.C.U.). Under the aegis of this body would exist and, we hope, flourish sections for as many as possible of the branches of sport: such as Football (Rugby and Association), Cricket, Swimming, Athletics, Hockey, Tennis, Billiards and Golf. Leagues could be formed, cup competitions instituted and the truly competitive spirit between the Departments fostered. By this means, also, properly representative teams could be selected to meet, on equal terms, teams from the banking, teaching, commercial and industrial worlds. New entrants to the Service would be speedily attracted and everyone would benefit. In this way, too, the Civil Service would gain in the esteem of the man in the street, and much of the ignorant and damaging criticism at present prevalent and popular respecting the Civil Service would be "scotched."

I would desire to appeal to all present secretaries and representatives of Service Sport to take this matter up. There should be no further delay. No existing organisation would suffer—in fact, all would inevitably benefit by union under the banner of the new organisation—and there is the great possibility that, having such an Association, representations could be successfully made to H.M. Treasury for the allocation of funds for the purchase of grounds or for the use of Crown Lands for the pursuit of Service sport. In any case, the formation of such an Association would be a move in the right direction, would give a welcome fillip to sport, and would inevitably benefit the health of the Civil Service, individually and collectively.

RICHARD R. COX,

[Referee, Civil Service Football League and London Business Houses Football League and Cup Competitions; Captain London Dock C.C. (Customs and Excise Cricket League); Editor, *The Civilian*.]

82/3, Lower Thames Street, E.C.3.

WEST YORKSHIRE TELEPHONE DISTRICT.

UNDER the auspices of the Traffic Discussion Circle, an enjoyable picnic was held on June 4 at Bolton Abbey. The journey was made by charabanc, and parties were made up at Leeds, Bradford and Dewsbury.

There was a good representative gathering, including many officers from Bradford and Dewsbury sub-exchanges.

The staff were very pleased to have with them Mr. Beaton, the Postmaster-Surveyor, and Mrs. Beaton; Mr. Lawrence, Postmaster of Dewsbury, and Mrs. Lawrence; Mr. Elliott, Assistant Postmaster, Bradford, and Mrs. Elliot; Mr. Riley, Superintendent of Telegraphs, Bradford, and Mrs. Riley.

The afternoon was spent in wandering through the woods, enjoying the beautiful scenery for which the district is noted. An excellent tea was provided at the Devonshire Arms, to which full justice was done. After tea the younger "bloods" indulged in sports. The sack race was well patronised by the ladies, and some of the entrants showed considerable skill in the manipulation of the sacks. A novelty race "speed of answer and disconnect" was also well patronised, and we look forward with hope that the entrants will show the same eagerness to "get there first" when engaged in their more serious occupation. What proved to be the most enjoyable and keenly contested event was, perhaps, the tug-of-war; there was keen friendly rivalry between the teams from Leeds, Bradford and Dewsbury. It would perhaps be inopportune to discuss the merits and demerits of the various teams, or how the winning team achieved success, especially as they were ladies, but we can, it is thought, without offence quote a remark which was heard on the ground, "Weight does tell, doesn't it?" Now, dare we mention the winning team? better not, perhaps.

The prizes were distributed by Mrs. Beaton, and Mr. Beaton, in the course of a few well-chosen remarks, said that such gatherings served a very useful purpose and that he hoped the example set would be followed by other branches.

All returned safely to their homes and turned up smiling on the Monday morning, voting that the outing had been an unqualified success, and expressing fervent hopes that they might be off duty for the next one, which we hope will be in September next.

MR. W. I HUNTER

of the Deal Post Office Staff, whom we congratulate heartily on winning the Amateur Golf Championship at Hoylake, at the end of last May. He created a record in the Amateur Championship by the margin by which he beat his opponent in the final. Mr. Hunter's photograph came to hand just too late for insertion last month.

MR. W. T. COOK

of the Central Telegraph Office, has had the honour of playing for Surrey several times this year. He scored 84 *v.* Sussex on his first appearance in first class cricket, and 71 *v.* Oxford. He also scored 101 and 65 for the Second XI. *v.* Wiltshire.

PERSONALIA.

LONDON TELEPHONE STAFF.

THE following resignations for marriage have taken place during the month of June :-

Miss E. T. COWLEY, Assistant Supervisor, Class I, of London Wall Exchange.
Miss F. E. IVE, Telephonist, of London Wall Exchange.
Miss K. M. WRANGHAM, Telephonist, of London Wall Exchange.
Miss E. F. BOURNE, Telephonist, of London Wall Exchange.
Miss M. E. N. KING, Telephonist, of Sydenham Exchange.
Miss E. MARSHALL, Telephonist, of Trunk Exchange.
Miss G. S. RICHARDSON, Telephonist, of Trunk Exchange.
Miss W. T. SMITH, Telephonist, of Trunk Exchange.
Miss L. WEEKES, Telephonist, of Trunk Exchange.
Miss M. V. FARQUHAR, Telephonist, of Paddington Exchange.
Miss V. WELLS, Telephonist, of Paddington Exchange.
Miss E. V. JOY, Telephonist, of Hammersmith Exchange.
Miss A. BURGESS, Telephonist, of Avenue Exchange.
Miss H. HITCHINGS, Telephonist, of Avenue Exchange.
Miss D. G. F. WALLIS, Telephonist, of Central Exchange.
Miss G. A. DAWSON, Telephonist, of Museum Exchange.
Miss E. M. COLEMAN, Telephonist, of Museum Exchange.
Miss J. E. SERVANTE, Telephonist, of Victoria Exchange.
Miss L. E. WILDMAN, Telephonist, of Victoria Exchange.
Miss M. E. BARRETT, Telephonist, of Victoria Exchange.
Miss D. S. WILLIAMS, Telephonist, of Victoria Exchange.

PROVINCIAL STAFF.

On April 28, Mr. HARRY ROSTANCE and Miss V. M. STEWART, both of the General Office, Sheffield, entered into a life partnership. On the eve of the wedding the bride and bridegroom elect were presented by their colleagues with a handsome oak timepiece.

Miss M. CARR, Writing Assistant, Sheffield, on leaving to be married on June 25, was presented by her colleagues with an oak clock.

Miss J. G. PEARSE, Telephonist, Devonport (Plymouth), was the recipient of a silver cake basket from the staff on the occasion of her marriage on June 1, 1921.

Mr. S. G. CAPLE, Clerical Officer, Traffic Dept., District Manager's Office, Plymouth, was presented by the clerical, operating, engineering and cleaning staffs with a set of rustless and plated cutlery on the occasion of his marriage on June 1, 1921.

Miss G. A. PEARCE, Telephonist, Plymouth, and Mr. HERBERT PETHICK, Telegraphist, Plymouth, were presented by the Postmaster's and District Manager's staffs with a silver tea service and glassware on the occasion of their marriage on June 4, 1921.

Miss W. PRIDEAUX, District Manager's clerical staff, Plymouth (formerly Telephonist, Plymouth), resigned for marriage on June 2, 1921. The staff presented her with a plated cruet.

Miss E. M. COOPER, Telephonist, Plymouth, was the recipient of an embroidered linen bed-spread from her colleagues on the occasion of her transfer to Yeovil as Senior Telephonist on July 10, 1921.

CALENDAR OF COMING EVENTS.

Aug.	3.	Cricket.	Cable Room *v.* Civil Staff Police at Paddington.
,,	4.	,,	Cable Room *v.* W. Norwood Social at Dulwich Park.
,,	5	,,	T.S. Foreign Annual Sports, Grove Hotel, Dulwich.
,,	9.	,,	Cable Room *v.* A. and B. Divisions at Dulwich Park.
,,	15.	,,	Commercial Cable Co. *v.* Cable Room, away.
,,	15.	Last date for entries for the 60 yards handicap open to all Ladies' departments of the Service, which takes place at the annual swimming gala of the Imperial Swimming Club (Trunk Exchange) (see L.T.S. Notes.).

THE BRAZILIAN TELEGRAPHS.

AT a time when the British Continental Telegraphs are well to the fore and great interest is being evoked the world over by automatic telegraphs and in view of the ever-increasing conquests of wireless, perhaps I may be allowed to occupy the reader's attention awhile with the origin and subsequent development of telegraphs in the great South American Republic of Brazil.

It will surely be of great interest to a large number to peruse a few facts concerning enterprise in other than European circles. Most of my data are culled from *Brazil Products and Manufactures*, a government publication, and I am also greatly indebted to the kindness of the Brazilian Vice-Consul here in London, who has rendered great assistance in the compiling of historical events coincident with the growth of telegraphs.

The birth of Brazilian telegraphy was due to the untiring efforts of Eusebio de Queiroz Coutinho Mattoso Camara aided by a competent helper in the form of the Professor of Physics, Dr. Guilherme Schuh. The initial stages of the telegraph service were inaugurated in 1852, but for a number of years developments did not proceed with great rapidity. However, the outbreak of the Paraguay War (1865-1875) necessitating speedy communications added great stimuli to the efforts of prominent engineers. In 1874 communication was established between Rio and Victoria (Espirito Santo), the next year saw Parahyba linked with the capital. The towns of Fortaleza 1881, Therezina 1884, and Para 1886, were thus connected in the early part of the next decade.

Internal lines were constructed about the same time to Curityba, Sao Paulo, Porto Alegre, and to the frontier of Uruguay at Jaquaràa.

The physical features of the country, however, are such as to present formidable barriers to the telegraph engineer. This led the State to obtain the services of the Amazon Telegraph Co. for the purpose of laying cables in the river Amazon. The principal cable commenced activity on Feb. 16, 1896, and served for providing Para and Manâos with direct communication. By this time, all the capitals of the various States forming the Republic were in telegraphic communication as well as towns, which were actual hubs of commercial activity. Progress was rapid, and each succeeding year saw further and greater development in telegraph construction.

The guiding influence and administration are in the hands of the Ministry of Public Works.

Not content with merely being alive to the necessity of adequate communication, the Ministry has keenly followed the example of European Administrations, and experiments were exhaustively carried out towards reaching the highest pinnacle of efficiency possible for maintaining a thoroughly reliable system.

In 1877 Brazil became an adherent to the International Convention of St. Petersburg.

The instrument extensively favoured was, and I believe still is, the Werner-Siemens polarised apparatus. Prior to this, Stohrers double Morse and Breguets with dial plates were originally the apparatus employed. 1885 saw Wheatstone apparatus in the service, followed in 1889 by the trials of modified Hughes-Maeyers automatic Morse, duplex with alternating currents, and Siemens quad. Steljes failed to give satisfactory results in 1894. Nov. 15, 1897, was a red-letter day, for on this date the Baudot was installed between Rio Janeiro and Sao Paulo. This inauguration after severe trials met with success, for exactly four years later a similar communication was established between Rio, Bahia and Pernambuco, the distance covered being somewhere in the region of 1,000 miles. A further development became operative in 1903 in a southerly direction between Rio and Porto Alegre and by repeater to Curityba with extensions to Pelotas and Rio Grande. The town of Fortalezza received Baudot double (or triple) installation on April 15, 1905, bringing up the distance of lines covered by this successful system to approximately 3,500 miles. The Hughes as we know it, did not meet with the same degree of success. Installed in 1900 at the central office (Rio) and at Petropolis and Juiz de Fora it met with but very little success. The reason is not definitely known, but exponents of the Hughes art would undoubtedly ascribe technical difficulty and incomplete tuition or inaptitude of operators as having some bearing upon its shelved position.

Digitized by Google

With regard to external communication the directorship, maintenance, &c., is in the hands of several "Sociétes des Telegraphes." Northerly, the cables are under the auspices of the French Transatlantic Telegraph Co., whose cables land near Salinas and the State of Para, and the South American Co., and the Western Co., whose cables land at Pernambuco. In the Southerly direction transit is provided by the cable of the Western Co., and aerial wires by way of Uruguay and the Argentine Republic.

The Eastern Telegraph Co. also, through the mutual agreement of the governments of the three Republics, Brazil, Argentine, and Uruguay, in 1899 provided a very important link with the outside world. The object of the inauguration of the French Transatlantic cable was to facilitate communication between Viven (Para), and the U.S.A. Commencing activities in 1892 the cable end had to be shifted at least twice on account of the powerful current at the mouth of the Amazon playing havoc with the shore end.

It was finally restored in 1907. The overland route passes from Porto Alegre and by three channels, these being—(1) Normal, by way of the Argentine. (2) Appointed, through the medium of the Eastern Telegraph Co.'s lines. (3) Optional, by the lines of the National Telegraph of Uruguay.

Also, to provide against isolation consequent upon possible interruption of the recognised routes an auxiliary line can be linked up by way of Quarahy-Santo Eugenio.

Before the advent of wireless, following the introduction of the electric telegraphs, messages were transmitted to and from ships by means of an elaborate system of semaphores round the coast, these were all linked by telegraph or telephone to the normal land lines. The more modern means has now replaced or is replacing the older and more cumbersome system.

W. H. GATEHOUSE,
Cable Room.

THE TOLL EXCHANGE.

BY CAPTAIN J. G. HINES, M.I.E.E.

A NEW exchange has just been completed which embodies some unusual features, and it is thought that a brief description of the installation will be of interest.

Hitherto the telephone traffic in the British Isles has been divided into two main classes, viz., local and trunk. The former class comprises all calls which do not pass outside the telephone area in which they originate. Sufficient junctions are provided to enable the majority of these calls to be completed on a no-delay basis. The second class comprises calls from one area to another. In the case of the trunk calls a certain amount of delay has hitherto been recognised to be unavoidable during the busy hours, especially on the longer lines. The cost of erecting and maintaining these lines is so heavy that they must be kept busy in order to prove remunerative.

The division between the two classes of traffic above-mentioned is not very sharp. A special fee is charged when calls are made between certain exchanges in the same telephone area. This involves the use of a ticketing system. On the other hand there are some towns which have so much traffic that trunk lines have been provided on what is practically a no-delay basis.

The trunk lines terminate in London at the Trunk Exchange, which is situated at the G.P.O. South. Owing to the nature and value of the traffic carried on the long trunk lines each operator handles the calls on two or three lines only.

In order to deal with the growing traffic on the shorter trunk lines a suite of 80 sections was installed in 1912 at the G.P.O. South in a room adjoining the Trunk Exchange. The suite was given the name "Toll," to distinguish it from the main Trunk Exchange. The installation was entirely carried out by the Sectional Engineer's local staff, and it was understood then that it was of a temporary character only, and would be replaced by a permanent exchange to which all the short distance trunks would be connected, thus affording much needed relief to the main Trunk Exchange. During the respite afforded by the opening of the temporary exchange, investigations were undertaken to determine the best means of dealing with the traffic on the shorter trunk lines and the longer junctions. It was eventually decided to remove all the short trunk lines (*i.e.*, up to 25 miles in length) from the Trunk Exchange and to connect them to one or more Toll Exchanges to be established in suitable positions. Sufficient lines would eventually be provided to enable the toll circuits to be worked on a no-delay basis, and an adequate provision of local junctions with a suitable grade of transmission for the class of traffic would also be made.

The traffic on the trunk and temporary toll exchanges at the G.P.O. South grew so rapidly however, that it was necessary to take further steps to relieve the immediate pressure, and in 1914 an existing building was acquired in Norwich Street, Fetter Lane, in which it was proposed to instal some switch sections as a temporary measure of relief. The outbreak of war stopped the scheme and instead of the dulcet tones of the operators, the building resounded to the strident notes of the sergeant-major and the beseeching request—it could not be called command—of the embryo officer.

Neither staff nor material was available for proceeding with the scheme and the fall in traffic removed the immediate urgency. At the conclusion of the War the trunk traffic increased and the scheme was revived.

Drawings and specifications were prepared by the Engineer-in-Chief and a contract was placed with the Western Electric Company for the internal equipment.

Plans were also prepared for a cable scheme which would enable the selected circuits to be diverted from the G.P.O. South and would also enable additional circuits to be provided to the towns which were to be included in the toll scheme.

The scheme includes new cables to the following towns :—

Hatfield and Welwyn.
Bishops Stortford.
Dartford, Gravesend and Chatham.
Purley, Caterham and New Oxted.
Ascot, Egham and Staines.
Dorking, Leatherhead and Cobham.
Pinner and Chesham.
Uxbridge, Beaconsfield and High Wycombe.

Some trunk circuits will be carried in the above cables and in addition other cables are being provided which will carry trunk circuits only.

During recent years much experimental work has been carried out in order to improve transmission over underground conductors, and the results of this experimental work have been embodied in the specifications for the new cables.

Considerable difficulties were met with in the work of laying the necessary conduits between Norwich Street and the G.P.O. South. Not only does the route between the two buildings carry some of the densest vehicular traffic in the world, but beneath the surface of the roads there is a mass of pipes of all descriptions. In Holborn it was necessary to excavate deeply and to lay the new conduits underneath a nest of conduits which had been laid by the Post Office some years ago. Still greater difficulty was met with in Ludgate Hill where gas mains, water pipes and sewers have had

Digitized by Google

to be diverted in order to find space for the Department's conduits. The difficulties have been surmounted, however, and a very valuable route has been secured. Opportunity was, of course, taken while the ground was open to provide sufficient conduits for the expected local, trunk and pneumatic tube development on this route.

Junction cables have been drawn in between the Toll Exchange and certain junction cable centres. Provision has also been made for extending to the Toll Exchange certain toll circuits which are carried in cables connected to the Trunk Exchange.

The actual number of toll circuits connected to the exchange at the opening is approximately 350 and the number of junctions is 600. On the completion of some cables now in hand the number of toll circuits will be increased to 540.

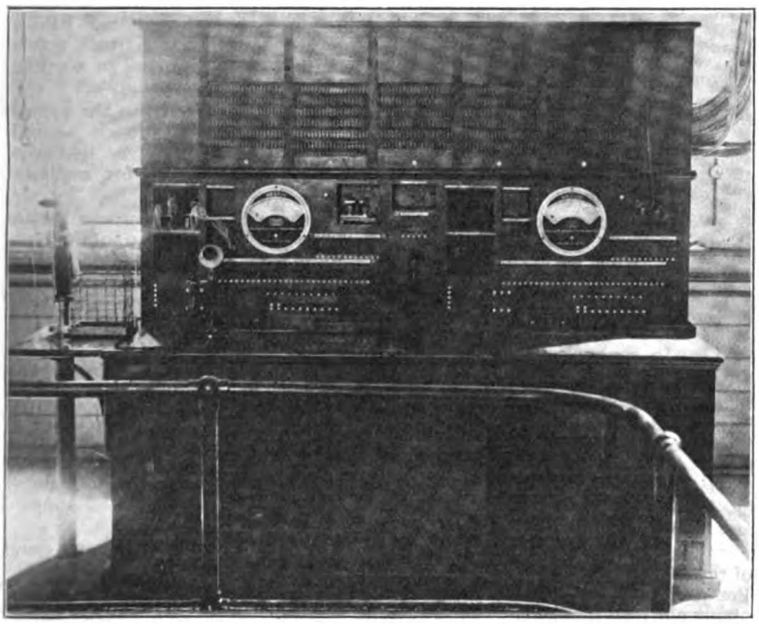

FIG. 1.—TEST DESK.

In anticipation of the opening of the exchange in Norwich Street, the name of the temporary exchange at G.P.O. South was changed from "Toll" to "Annexe" and the suite of sections will serve as an overflow to the main Trunk Exchange.

As the acquired building had not been designed for telephone work the exercise of some ingenuity has been necessary in order to use the space to the best advantage. The power plant, distribution frames, test desk, batteries, repeating coil and relay racks are on the ground floor. This plant is generally of standard design with modifications to suit the particular equipment and class of circuit. The two main batteries each have an ampere hour capacity of 1,750 hours, and are fully equipped. The voltage is 22. Two auxiliary batteries are provided each having a capacity of 315 ampere hours. There are two motor generators each having an output of 260 amperes at 26 volts.

A novel feature is the provision of a test cabinet over the test desk through which all the toll circuits are led on break jacks. It is thus possible for the testing officer to test both the internal and external portion without moving from the desk or obtaining special connexions. (Fig. I).

The switch sections are located on the third floor and on a gallery which partly surrounds this floor. Fortunately the natural lighting is fairly good, although the positions of the lights are not arranged as they would be in a building specially designed for telephone work. (Fig. II).

The switch sections are of the Number 10 C.B. type with two panels per section, each section forming one position.

Sixty of the sections are equipped with 10 answering jacks and lamps for incoming local junctions. These sections are termed "Control" positions. They are equipped with 12 cord circuits each and have a capacity for 17. Provision is made for concentrating all the incoming jack-ended junctions upon 20 selected positions at slack periods.

Thirty sections are each equipped with 20 answering jacks and lamps for incoming toll lines and are provided with 17 cord circuits per position.

Provision is made for concentrating the incoming toll lines on 10 sections when required.

Three sections are equipped with 30 plug-ended junction circuits and will be used for circuits incoming from the Trunk Exchange.

Two six-panel multiples are provided. The upper is for junctions to local exchanges and comprises 500 jacks per multiple. The lower is for working to provincial exchanges and also comprises 500 jacks per multiple, but is divided into two parts. One part containing 380 jacks is further divided into groups of four working lines and one test jack. The latter, which is the first jack of the group, will test engaged if all the four working lines are in use. The test jack is fitted with a metal plug of conical shape to facilitate the operation of testing.

The second part of the multiple, containing 120 jacks, is not provided with group testing jacks.

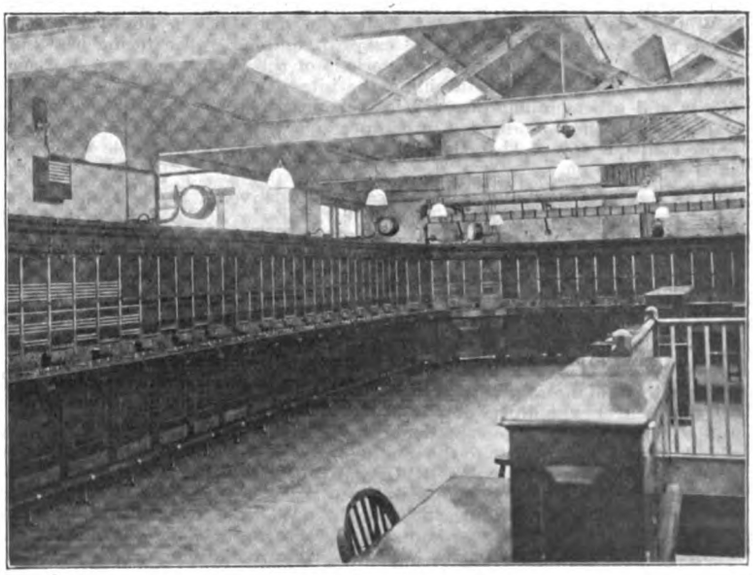

FIG. 2.—PORTION OF SWITCHROOM.

The two parts of the multiple are separated by a spacing strip.

Two one-position and two four-position desks are provided for supervising purposes.

The number of different electrical circuits of varying degrees of intricacy is over 70. This is not great compared with some exchanges, but is an indication of the complexity of a modern telephone exchange compared with those that were constructed 25 or 30 years ago, when the number did not, as a rule, exceed half-a-dozen.

THE REVISED SYSTEM OF DELIVERING TELEGRAMS.

BY MAJOR A. A. JAYNE, D.S.O., O.B.E., M.C.

THE authority given by the Postmaster-General recently for the introduction of the Revised System of Delivering Telegrams marks an advance for the Telegraph Service more far-reaching than the local character of the change indicates. It is true that an improved delivery service will result, in addition to a large annual saving, but above all it points the way to a better regulation and control of traffic than has ever yet been contemplated in our Service. We will first of all look at the Revised System. It is based upon the following principles :—

A. The division of telegraph delivery areas into definite walks radiating from the delivery office so arranged that the time occupied for each walk will be so far as local conditions permit of approximately equal duration.

B. A pre-arranged time table for the despatch of the messengers on their walks.

1. Messages will be despatched from the sending-out point in the delivery room at intervals of 10 minutes in the case of Head Post Offices and Branch Offices where the traffic is received by tube from the Central Office, and at 15 minutes' intervals at Branch and Town Sub-Offices where the traffic is received by wire.

In connexion with A. the delivery area should be divided into walks after the density and direction of the traffic has been ascertained. For this purpose returns showing the time of receipt at the sending-out point and particulars of the "address to" should be taken for the *busy hour* on *three representative* days of the week. The direction and density of traffic for each 10 minutes, or 15 minutes' interval should be plotted on maps of the whole area by means of coloured pencils; each interval being indicated by red, black, violet, green, blue, and yellow pencils respectively. A separate map for each day is required. When the average density and direction of the busy hour traffic for the three days has been ascertained the probable duration of the journeys should be estimated and the proposed walks radiating from the delivery office should then be marked on a delivery map. At some offices the direction and density of the traffic are already known and in this case walks should be marked off on a delivery map without returns. Observations will reveal the need for any adjustments of boundaries. It is important that the maximum number of walks for the busiest hour should be taken as a basis. It will then be easy to combine walks during less busy times of the day and during slack periods of the year, when less messenger force is required, while maintaining the integrity of the walks. At Class I offices and other similar busy offices certain walks have dense zones. The walks should then be divided into Inner and Outer Zones. The whole walk being sent out say at 11.0, the Inner Zone at 11.5 and the whole walk again at 11.10 and so on.

In cases where batches of messages are delivered to the same address (*e.g.*, commission agents), the number of addresses to be dealt with should be taken into account and not the actual number of telegrams delivered.

2. As regards "B." The messages as they arrive at the sending-out point should be sorted into shallow trays corresponding with the walks and entered as soon as possible on the messengers' dockets (T. 155) by the sending-out officer. At busy delivery offices the sending-out officer should be assisted by a messenger whose knowledge of the delivery area would enable him to sort the messages. It is convenient to have separate trays for addressees who receive large batches of messages in order to obviate subsequent sorting by messengers. The messengers should be despatched promptly in accordance with the time table. Immediately after the departure of one relay of messengers the next should hand their dockets to the sending-out officer and take up their positions near the sending-out point. "Urgent" (triple-rate) and other special telegrams should be sent out *at once* but other telegrams for the appropriate walk may be delivered after the "Urgents." Where there are many "urgents" one or two extra messenger-hours should be arranged so that the special journeys have the effecting of improving the quality of service.

3. As a preliminary to the permanent adoption of the system the following procedure provides a ready means of obtaining statistics for calculating the staff required on delivery work. After arrangements have been made as in 1 and 2 the system should be brought into force for three full consecutive days with the normal messenger force on duty and returns taken in the form shewn on Appendix A. A summary of the information shown on Appendix A should be prepared on Appendix B.

4. The result of the preliminary trial (paragraph 3) may necessitate some adjustment of boundaries either for the purpose of equalising the duration of journeys or for effecting reductions of force. 'Full' sorting should be maintained throughout the day, but the returns will show the extent to which walks may be combined during the slack hours. It follows that the full force of messengers will not be required for delivery purposes during the less busy hours, and it is during these periods that resting time, meal reliefs, and educational facilities where given in official time should as far as possible be arranged.

5. At many offices the demands of Express Letter Services present difficulties in the maintenance of a sufficient number of messengers for telegraph delivery work.

As regards Service 1 it has been found economical to have the Express Letters brought from the counter to the delivery room where, if they fall within the normal telegraph delivery area, they are sorted to the walks and sent out with the next periodical despatch. If they are outside the area and the use of public conveyance all the way is necessitated they should be sent out at once; otherwise they should be sorted to the most appropriate walk. In cases where requests for Express Messengers are received by telephone, the address of the Express packet should be ascertained to enable the sending-out officer to determine whether it should be brought to the delivery office for sorting or delivered direct. Where necessary, one or more messengers should be allocated for this service throughout the day in order that the regular walk arrangements may not be unduly disturbed.

Service II. These letters if for an address within the normal delivery areas, should be sorted into the ordinary walks for delivery. If outside, they should be included in the most appropriate walk. If this is done during the preliminary trial the average duration of journeys will automatically include this service.

6. In order that there may be no leakage of messenger force it is important that certain services such as the following should be organised and the walk system used to the fullest possible extent.

(i) Telegrams for the Postmaster's offices or other offices in the building should be sorted into walk No. 1, and central points at which telegrams should be left for various branches or sections should be arranged and notified to the sending-out officer.

(ii) Telegraph Money Order advices, should be delivered to the proper officer at the counter and the messenger should at once proceed on his walk. When the necessary order for the payee has been prepared it should be sent to the delivery room for ordinary treatment.

(iii) Requests to the delivery room for messengers to convey letters and packets specially to offices within the building or to subordinate offices outside should be restricted as far as possible. All covers of an urgent character should be sent to the delivery point for inclusion in the usual walks. Non-urgent communications should fall into the ordinary postal delivery.

7. In connexion with the study of the foregoing method of delivery, the average time occupied in delivery to addresses under both the present and the new system should be ascertained.

8. At offices where the walk system of delivery has been tried it has been practicable to suspend certain branch and town sub-office deliveries by the concentration of the delivery work upon the Head Office. The total transit time of telegrams has not been materially increased while economy has been effected inasmuch as both telegraph transmissions have been avoided and messenger force saved.

A very senior p.s.c. staff officer once remarked to me that "the worst of technical services is, that they always quarrel among themselves." In the Post Office we do not exactly quarrel but we are all so frightfully enthusiastic about our own particular way of looking at problems that we are inclined to become somewhat parochial in our outlook. This cannot be said of the attitude adopted by responsible officers all over the country, in regard to the Revised System when it was first tried. Certainly, it was pointed out that a neighbouring hilly town would be more suitable for the system than the flat town we were in and *vice versa*, and in other places that the traffic was too dense or not sufficiently dense, in short that in other towns it would be quite practicable but not in the particular one under notice for some abstruse reason. As soon as a short demonstration was made, however, nobody could have been more helpful or enthusiastic than the local officials.

As regards paragraph 1 above, it is quite clear that the average sending-out times are improved, if times under the old system are impartially compared with those of the new. Whatever system is used there is a certain amount of preparation work to be done, such as sorting into routes, entering on dockets, &c. This is not delay any more than any other necessary treatment during the transit of a telegram. Under the old system there was no prearranged route—the route of the messenger was determined by the addresses of the telegrams on hand and when the messenger had been despatched a fresh route was made up. In what manner succeeding routes clashed with those that had gone before no man knoweth, but it was fairly indicated by the puzzling mystery of three or four messengers strolling down a street together. However, everybody was quite happy if the few messages actually being dealt with were sent out comparatively quickly regardless of the delay accumulating in the message cage. It was based on the theory of individual delivery which like other theories did not evolve into practice. And then came that awful period of messages waiting and no messengers! What was the explanation?—"shortage of messengers." Does not everyone know too of the times when messengers would be sitting down, idle, and no messages to be sent out—always the occasion for a Inspecting Officer to come round and demand reduction of force; and how between the requests for increased force and reduction of force everybody concerned "gave it up." Now, however, the routes are prearranged by means of walks, there is a fixed interval at which batches are to be despatched; and the average time within which the messages are to be sent out is laid down. Leaping into the dark should be a thing of the past, as should be shortage of messengers, while it ought to be a very long arm of coincidence to account for messengers walking or cycling on a route together. In some cases different series of walks have to be arranged at different hours of the day, for example, the delivery from the C.T.O. at different times of the day is affected by Billingsgate, Smithfield, the lunch hour, Stock Exchange opening, and the like.

APPENDIX A.

Office..... *Date*.....

DELIVERED TRAFFIC RETURN.

HOUR.	WALK NO. 1.			WALK NO. 2.			WALK NO. 3.		
	Messengers' No.	No. of Messages.	Time of Messengers' return.	Messengers' No.	No. of Messages.	Time of Messengers' return.	Messengers' No.	No. of Messages.	Time of Messengers' return.
	Examples :—								
8. 0	12	SI	9.10	—	—	—	—	—	—
8.10	22	4	8.35	18	3	8.29	14	5	8.36
8.20	13	3 IE	8.45	11	(3) + 2	8.40	16	2 2E	8.50
etc.									

NOTES :—

S. Indicates Express letter sent out specially under Service I.

E. Signifies Express letter sent out with a batch of telegrams.

(3) Signifies 3 telegrams for one address. To be counted as 1 in the Summary.

APPENDIX B.

Office..... *Date*.....

SUMMARY OF DELIVERED TRAFFIC RETURN AND DELIVERY FORCE REQUIREMENTS.

Hour and Number of Journeys.	Number of items delivered :— See Appendix A.			Total time occupied in delivery.	Average duration of journey.	Average number of addresses per journey.	Number of Messengers required each hour.					Existing Messenger Force
	Telegrams for separate addresses.	Express Letters delivered.					In respect of Column (5)	As an addition to Column (8) for rest during slack hours.	For educational facilities (where given in official time).	For meal reliefs.	Total	
		In walks.	Specially (Service I)									
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	

NOTE :—The periods covered by columns (10) and (11) are to be taken into account as resting time.

It should be made quite clear that the " Revised System " is not one that should be started off and then left severely alone. It requires regular and frequent overhauling at every office ; traffic observation in this direction will be remunerative and Appendixes A and B have been designed to make it easy.

The time table is really the basic principle of the system. Without this no proper method can be introduced. Life cannot be imagined without time tables, and it is difficult to visualise a proper messenger delivery service at a busy telegraph office without them. Here at once there is an objective for telegraph offices to work up to. At every office there should be a standard time for a message to be collected from the circuit, taken to the circulation table, addressed and enveloped, and despatched to the delivery room. That is to say, at a fairly large office that has despatches every 10 minutes, messages received at circuits at 11. 57 should be received in the delivery room in time to catch the 12 o'clock despatch. I can hear my readers saying " there is the weakness, the messages received at 11.58 will not be despatched until 12.10 p.m." That is so, of course, and my reply is that under the old system it would probably not be despatched until *after* 12.10 p.m. Having regard to all that depends upon the System, staff matters, efficiency, standards of working, &c., it is surely better to have an average sending-out time from circuit time of say 6 minutes, than for a few messages to go out with 6 minutes' transit time and very many more with 15 minutes and over.

Paragraph 2 provides much needed relief to sending-out officers at busy delivery offices. Instead of mental gymnastics in order to find the best combination of telegrams for routes, particularly in cases where the sending-out officer does not know the area, efforts to find the messengers next for going out, dealing with the boys continually returning, meeting demands for messengers to go on express services and so on, the sending-out officer will have a properly regulated interval in which to prepare his next despatch. Comparative calm will reign in the delivery room, for the last boy in will take his seat next to the messenger who returned just before him and then when the despatch is made, the next relay of messengers will move up to the best position for the sending-out officer.

Paragraph 6. For some mysterious reason everybody has the idea that a messenger's time is not worth very much and that, therefore, his services may be most generously taken up for all sorts of minor tasks. As a matter of fact an *effective* messenger hour costs the Post Office something in the neighbourhood of 2*s*., and I hope this fact will cause all concerned to see that it is not frittered away. A messenger should not be put on a duty where he can only occasionally do something useful. A great deal of the economy effected under the scheme is due to the attack it automatically makes on the leakage of messengers from their proper work of delivering telegrams. At many offices it is the practice to ring a bell for a messenger to take a note or a return, frequently of no urgency, to another part of the building, a small parcel of stationery to a sub-office or a bundle of forms to another Department. Where the new system is properly brought into force, that is to include all such missives in the walks, the amount of leakage that must have taken place under the old system can be seen at once.

Paragraph 8 is most important. It will often be found that telegrams can be delivered quicker from the Head Post Office than from a local Branch Office if internal circulation and line time are taken into account. The economic gain is obvious.

As already indicated the principal advantage of the Revised System is derived from the fixed time table. The time table could have been fixed at any interval desired, but *there must be a time table*. It discloses the weak spots and renders a correct revision of force an easy matter ; without it there is no basis upon which an efficient delivery service can be built up

(To be continued).

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

BY F. ADDEY, B.Sc., M.I.E.E., FELLOW I.R.E.

(*Continued from page* 173).

The valve is joined up as shown in Fig. 14. The filament is made to glow by the battery B_1, the strength of the heating current being controlled by the adjustable resistance R. The grid is joined to one side of the condenser C_1, and the other side of this condenser is joined to the filament, not directly, but through the potentiometer R_1. By means of this potentiometer the potential of the grid can be brought to any desired value above that of the negative end of the filament, up to the limit set by the electro-motive force of the battery B_1, the connection between the slider of the potentiometer and the grid being by way of the coils S_1 and P_2.

The high tension battery B_2 has its positive pole joined to the anode of the valve through the coil S_2, while its negative pole is joined to the negative terminal of the filament.

The potentiometer R_1 is adjusted so that the grid is brought to a potential corresponding to about the middle of the steep part of the characteristic curve of the valve. For the curve in Fig. 13 this potential would be about a quarter of a volt. The anode current which will flow through the valve can then be read off the curve. For Fig. 13 its value would be 0.35 milliamperes.

The anode current will remain steady at this value as long as the grid potential remains unchanged. Any alteration in the grid potential, however, will have an immediate effect on the strength of the anode current.

When signals are being received, and the intermediate circuit is set into oscillation, the potential between the plates of the condenser C_1 will oscillate, the potential of the plate joined to the grid being first a certain amount above and then nearly the same amount below the potential of the plate joined to the filament, and so on alternately as long as the oscillations last. These alternating potentials will be super-imposed on the steady potential given to the grid by the potentiometer. Suppose the potential of the grid alternately to rise and to fall by a quarter of a volt, that is first to rise half a volt above the negative end of the filament, and then to fall to the same potential as the negative end of the filament. Referring again to Fig. 13, the effect of these changes in the grid potential will be that the anode current will alternately rise to about 0.41 milliamperes, and fall to about 0.29 milliamperes, a change in each direction of about 0.06 milliamperes from its steady value of 0.35 milliamperes.

Since the characteristic curve is a straight line for some distance on either side of the point to which the grid voltage is adjusted by the potentiometer, it follows that the changes in the anode current produced by fluctuations in the grid voltage will be proportional to these fluctuations, so long as they are not great enough to reach the parts of the curve where it begins to bend over. That is, because a change in grid voltage of a quarter of a volt in either direction produces a change of 0.06 milliamperes in the anode current, a change of grid voltage of one eighth of a volt will produce a change in the anode current of 0.03 milliamperes, and so on.

Consequently, any regular or irregular changes of grid voltage whatever within the limits mentioned will cause exactly similar fluctuations in the anode current. If both the grid voltage changes and the resulting anode current fluctuations be plotted as curves in the ordinary manner, the horizontal scale of the curves representing time, these curves will be of exactly the same shape.

This proportionality between grid voltage and anode current is of special importance in connection with wireless telephony, as will be explained later.

The pulsations in the anode current will occur in step with the variations in the grid potential, which latter occur at the same frequency as the oscillations in the circuit S_1 P_2 C_1. The anode current pulsations in the coil S_2 set up alternating electro-motive forces in that coil by virtue of a property called its "self induction," the electro-motive force being in the same direction as that in which the anode current is flowing when a pulse of anode current is diminishing in strength, and in the opposite direction when a pulse is increasing in strength.

Because of the steepness of the slope of the characteristic curve, however, a small change in grid potential will produce a comparatively large change in anode current. As a result of this the electro-motive forces set up in S_2 by the pulsations in the anode current will be considerably greater than the potential changes at the grid by which they are originated. Thus we have alternating electro-motive forces set up in the circuit S_2 C_2 of the frequency to which the circuit S_1 B_2 C_1 is tuned, and therefore also of the frequency to which the circuit S_2 C_2 is tuned, because, as explained above, all three oscillatory circuits in the receiving apparatus are adjusted to the frequency of the incoming signals. The connexions of the apparatus are so arranged that the successive pulses of the oscillatory electro-motive forces set up in this way in the coil S_2 occur not only at the same times but also in the same directions as those of the other electro-motive forces in that coil induced directly from the oscillations in the coil P_2. Thus the two oscillatory electro-motive forces in S_2 assist one another in setting the circuit S_2 C_2 into oscillation, and the amplitude of these oscillations will be considerably greater than that of the oscillations which would be set up by the unaided electro-motive forces induced in the coil S_2 from the oscillations in the circuit S_1 P_2 C_1.

But the increase in the strength of the oscillations in the circuit S_2 C_2 does not end at this point. The oscillations in S_2 C_2 will react back on the circuit S_1 P_2 C_1 across the oscillation transformer S_2 P_2. The connexions of the apparatus are so arranged that the electro-motive forces set up in the coil P_2 by this reaction help the oscillations which have already been set up in the circuit S_1 P_2 C_1. Consequently the amplitude of these oscillations is increased, the potential changes applied to the grid become greater, and these give rise to larger pulsations in the anode current and more intense oscillations in the circuit S_2 C_2.

The same train of actions is then repeated, and the amplitude of the oscillations in the circuit S_2 C_2 continues to increase till the energy losses in the various circuits due to resistance, &c., which increase more rapidly than the current increases, just balance the energy supplied to the circuits from the high tension battery and from the incoming signals. Thus the amplitude of the oscillations in the circuit S_2 C_2 is very much greater than it would be if the valve were not used, and as a consequence the signals in the telephones are very much louder.

For receiving spark signals the circuits are so adjusted that directly the supply of energy from the aerial due to the incoming signals ceases, the energy losses in the various circuits are greater than the supply of energy from the high tension battery, and so the oscillations stop. It is possible, however, by making suitable adjustments, to arrange that the energy losses may be completely made good by the supply from the high tension battery. In these circumstances the circuits are in a state of unstable equilibrium, and the least electrical disturbance will cause the oscillations to start. In fact, with the proper conditions it is not possible to avoid starting the oscillations. Once started, they will build themselves up till the stage is reached at which the loss and gain of energy just balance, and then they will continue with a constant amplitude.

Digitized by Google

These conditions are not required for the reception of spark signals. They are, however, required for the reception of continuous wave signals, and for the generation of oscillations for transmitting purposes, as will be explained later.

The condenser C_4 (Fig. 14) joined across the high tension battery B_2, is to facilitate the production of the pulsations in the anode current. This condenser is kept charged by the battery B_2, and may be looked upon as a battery of low internal resistance. As the effective resistance of the valve rises and falls as the grid potential varies the anode current is varied in a corresponding manner by the discharge from the condenser, the charge in which is replenished by a more or less steady flow of current from the battery B_2.

Rectification.

In the receiving set just described the valve was employed to amplify the received oscillations before they were rectified by the crystal detector and so rendered audible on the telephones.

It is possible to use a valve in place of a crystal detector for rectifying the signals. When this is done an increase in the signal strength can also be obtained, if a suitable valve used under proper conditions be employed.

Referring to the diagram of the crystal detector, Fig. 10, it will be remembered that, when signals are received, oscillations occur in the closed oscillatory circuit. These oscillations cause alternating potential differences to be set up between the plates of the condenser in that circuit. The crystal detector, potentiometer and telephones are joined across the condenser, and since the potentiometer has been adjusted so that the steady voltage applied to the crystal detector is that at which the characteristic curve, Fig. 9, bends up sharply, these oscillations will be rectified, as already explained, and a sound will be produced in the telephones.

The crystal detector characteristic curve shows the connexion between the voltage applied to the crystal, and the current through the crystal and telephones. The action of the detector depends on the existence of the sudden bend in the curve. The characteristic curve for a valve, Fig. 13, shows the connexion between the voltage applied to the *grid* and the current flowing in the *anode* circuit. It will be seen that there are two bends in this curve, one at about—2 volts grid potential, and one at about+2 volts grid potential. If the grid voltage be adjusted to—2 volts a very small anode current will flow. An alternating voltage superimposed on this steady voltage will cause a considerable increase of current when the voltage pulse is in the positive direction, but there will be only a slight diminution of current when the voltage pulse is in the negative direction. Thus the effect in the anode circuit when an alternating potential is applied to the grid will be similar to that produced when an alternating voltage is applied to the crystal. Unidirectional pulses of current will be set up in the anode circuit, and these can be caused to effect a telephone, as in the case of the crystal detector.

If the grid voltage be adjusted to about+2 volts, then a negative voltage pulse on the grid will cause a considerable decrease in the anode current, while an equal positive pulse will cause only a slight increase in the anode current. An alternating potential applied to the grid will thus produce pulsations in the anode current below its normal value. A telephone in the anode circuit will be effected by the diminution in the current, and the signals will be reproduced. It must be remembered that a sound is produced in a telephone by either an increase or a decrease in the current flowing through its coils.

The connexions of a receiving set using the method just described, which is known as " anode rectification," are shown in Fig. 15. The arrangement of the various oscillatory circuits is similar to that already described. For simplicity only the aerial oscillatory circuit and one closed oscillatory circuit are shown. An intermediate oscillatory circuit, similar to that shown in Fig. 14, could of course be introduced. The grid of the valve is joined to one side of the condenser, C_1, of the final oscillatory circuit, the other side of this condenser being joined to the slider of a potentiometer R_1. B_1 is the filament heating battery, and B_{11} is an extra battery joined in series with B_1. The potentiometer resistance R_1 is joined across both B_1 and B_{11}. The addition of B_{11} enables potentials lower than that of the negative end of the filament to be applied to the grid.

By this means a sufficient range of voltage is available on the potentiometer to enable either bend in the characteristic curve to be used, as may be desired.

The positive pole of the high tension battery B_2 is joined through the telephones to the anode of the valve. The negative pole of B_2 is joined to the negative terminal of the filament.

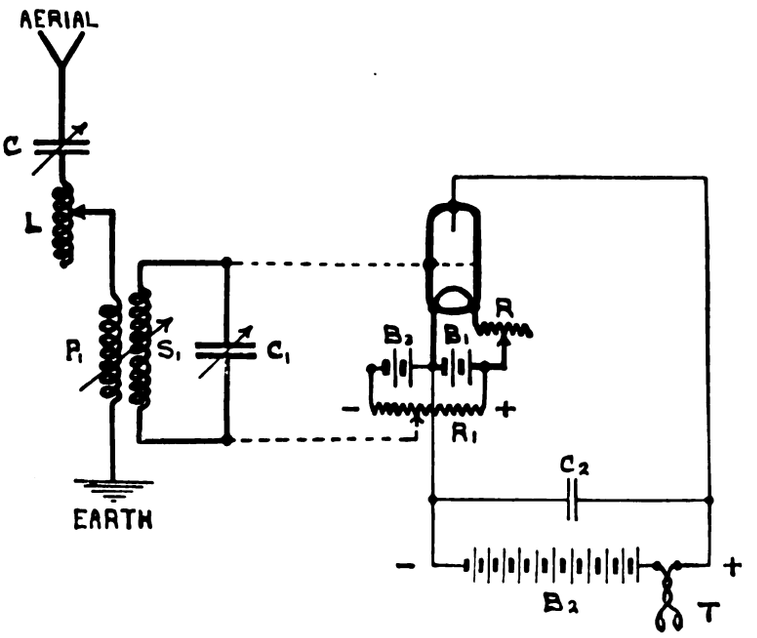

FIG. 15.—ANODE RECTIFICATION.

Across both the high tension battery and the telephones is joined the condenser C_2. When signals are received the alternating voltages across C_1 will be applied to the grid, and, as described above, the anode current will be caused to pulsate. As explained in the case of the high frequency amplifier, Fig. 14, these pulsations will actually be supplied by the condenser C_2 joined across the high tension battery, and the charge in this condenser will be adjusted by a steady flow from the battery. Since the telephones are joined in series with the battery, the change in the current through them due to this adjustment of the charge in the condenser C_2 will cause a sound, and so the signals can be read.

In the crystal detector the energy of the received signals is directly applied to the telephones. With the valve detector just described the energy applied to the telephones is drawn from the high tension battery, the received signals being used only to control the supply of this energy. Consequently, with proper adjustments, considerably greater energy can be applied to the telephones by the use of a valve detector than would be possible with the crystal detector, a corresponding increase in the strength of the signals being obtained.

In Fig. 15 the voltage applied to the grid is that due to the incoming signals alone. It is, of course, evident that a high frequency amplifier could be applied to the oscillatory circuits, as in Fig. 14, to increase the voltage applied to the grid and so to increase still further the loudness of the signals in the telephones.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.1. The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VII. SEPTEMBER, 1921. No. 78

OUR SEVENTH VOLUME.

THE present issue completes our seventh volume, recording the progress of a year during which much sharp criticism has been continuously levelled at the Post Office and all its works, and more especially at the Telephone Service. Criticism is doubtless good for our moral health, provided it be fair. Unfair criticism, and it has been plentiful, we have endeavoured on occasion to rebut; but with a Parliamentary Enquiry sitting on the telephone question, many points on which we should have liked to touch, we have, perforce, as a semi-official journal, had to consider as *sub judice* and to leave alone. Amidst a clamour on the whole unfriendly and discouraging, the whole staff of the Post Office have one aim in view, namely, the improvement of the service, and reference to our pages will show that a gradual reversion to pre-war standards of operating has been achieved, that the system has steadily increased, notwithstanding set-backs due partly to the trade depression consequent on the long-extended coal strike and the cessations due to the new rates. As far as can be estimated from the latest returns the number of telephone stations at the end of July will show an increase of about 25,000 on the total at July 31, 1920.

In the Telegraph Service many pre-war facilities have been restored to the Press and the public. The Anglo-Continental Service has been extended, the channels to Holland have been increased, and direct circuits provided to Dresden, Prague and Leipzig. Siemens fast speed apparatus has been introduced on the London-Berlin Service, and Baudot working on the London-Hamburg and London-Berlin lines. Direct wireless working between London and Berlin has also been successfully established, and it is hoped shortly to open a high-speed Wheatstone wireless service to Cologne. Meanwhile experiments are proceeding for the application of tape-perforating on the Anglo-Continental Service.

We have to record with great satisfaction a steady flow of interesting contributions from all grades of the staff. Our articles have come from the pens of high administrative and engineering officials, traffic officers, clerks, engineers, contract officers, telegraphists and telephonists of all ranks. This is a gratifying fulfilment of the scheme of the JOURNAL which was to form a open court for discussion and exchange of opinion by all members of the staff. Wireless questions, as is naturally, since they loom so large in the prospect at present, have played a greater part in our pages than heretofore, while we have endeavoured to keep our readers informed of the principal happenings in the telephone and telegraph services abroad. As regards the former it will have been observed that, as a result of abnormal economic conditions everywhere, greatly increased rates are the almost universal rule. We have regularly recorded the sports and social doings of the staff, and especially the endeavours in the cause of charity which are so much to the credit of the telephonists.

We look, therefore, to the future with every confidence, and trust that our contributors and well wishers will not relax their efforts in bringing matters of interest and instruction to our notice. We should like to see the JOURNAL circulate more extensively in the smaller provincial towns, especially those which have no District Manager of Telephones. We feel assured that telegraphists in the smaller places would find much to interest them in the JOURNAL; and, above all, it is our desire that its space should not appear to be monopolised by London and the larger cities.

HIC ET UBIQUE.

THE Leafield Wireless Station, Oxfordshire, was opened on Aug. 18. The station, which has been entirely designed by the Post Office, will communicate with the corresponding station at Abu Zabal, near Cairo. The Postmaster-General sent the first messages from the station to all British and foreign telegraph stations within range. Within half-an-hour replies were received from Malta, Paris, Christiania, Posen, Prague, Denmark, Budapest, Rome, and Berlin. It is hoped to have a descriptive article on the Leafield station in an early issue of the JOURNAL.

MR. V. M. BERTHOLD, of the American Telephone & Telegraph Co., has kindly sent us a short history of the telephone and telegraph in the Argentine Republic which he has written. The pioneer of land telegraphs in that State was the Western Railway who opened a short line in 1857; and a submarine telegraph to Monte Video was opened in 1866. Communication between Buenos Aires and Rosario was established in 1868. The total telegraph mileage in 1919 was 268,863 km. Telephone service was opened by private companies in Buenos Aires in 1881, but in 1886 the companies amalgamated and were taken over by an English company, the United River Plate. This Company now has about 80,000 stations, and a Co-operative Society about 8,000.

THE new German telephone rates to which we referred in our last issue have been approved by the Reichstag and will come into force on Oct. 1 next. We have also received full particulars of the new Austrian rates. In Vienna a subscriber making 40 calls a day pays 36,000 kronen, making 24 calls he pays 14,400 kronen, and making 12 calls a day 6,840 kronen. It seems useless to try and convert these charges into English currency at the present fluctuating

Digitized by Google

rates of exchange, but if the krone is worth only a halfpenny in spending-power to the Viennese subscriber, he pays £75 a year for a service including 40 calls a day, or £14 5*s.* for 12 calls a day.

WE observe that Capt. Walter Elliot, M.P., has suggested the provision of jazz-bands for the recreation of jaded telephonists and other postal workers. Can it be that Capt. Elliot has dipped into No. 53 of the JOURNAL and lighted on the verse—

> "That Illingworth foldeth his hands
> While his flappers are flirting, or follow
> The lure of Jazz-bands!"

Or were we prophetically inspired in 1919?

SOME of the contemporaries, commenting on the recent tax on wireless plant in France, adopted different methods of converting the charge (10 francs) into British currency. The *Daily Mail* and the *Evening Standard* arrived at results of 8*s.* 4*d.* and 8*s.* respectively, while *The Times* quoted 4*s.* 5*d.* The calculations being made on the same day (July 23) are strictly comparable; and Smith Minor is also anxious that his "pot shot" may be regarded as a serious calculation.

Our readers are probably aware that the Madrid International Conference adopted a mint par rate of exchange of frs. $25.18^{2.5}$ (gold)=£1. And on this basis, francs 10=7*s.* 11.3*d.*

WHAT ZAZA SAID TO ADRIAN.

In the House of Commons yesterday, the Postmaster-General told a story against the telephone system of a much-worried Member of Parliament who crawled home through the dawn, very tired after an all-night sitting. He had just tucked himself comfortably under the blankets when the telephone bell began to ring downstairs. Cursing, he answered it and received the message in a feminine voice completely unknown to him: "Adrian, I am now ready to come home." "Who are you?" he asked. "I am Zaza," said the lady. The Member never knew who Zaza was, but Mr. Kellaway said his story illustrating the difficulty of distinguishing between nine and five in a telephone number during the early hours of dawn.—(*Northern Daily Mail.*)

Oh, never since romance began
A mystery our soul has vexed
Like that suggested by the text:
What Zaza said to Adrian.

We have a Woman and a Man,
A pair of Telephones—but that
Yields little clue for guessing at
What Zaza was to Adrian.

In vain the brief remark we scan:
"I am now ready to come home,"
For who could make a decent pome
On Zaza's words to Adrian?

Had she eloped with Florestan,
And, harrassed by repentance wild,
Bethought her of her blue-eyed cheild
And telephoned to Adrian?

Conceive her feelings, if you can,
When in the dawn, long after two
Some Member bellows: "Who are you?"
Some Member, and not Adrian!

Or was she merely of that clan
Who dance all night, and then expect
A toil-worn husband to collect
His Zaza—hapless Adrian!

We give it up; and rather than
Weave unsubstantial fictions round
A cross-connexion, say: "Confound
What Zaza said to Adrian!"

W. H. G.

TELEGRAPHIC MEMORABILIA.

STRANGE are the vicissitudes of International Telegraphy! It is an interesting comment on the condition of certain parts of Europe that, as one writes, one of the most reliable telegraphic routes between this country and Italy is actually that through Berlin and/or Frankfurt Main, the former for preference. This has very largely been made possible by a steady improvement in Baudot working between London and the German capital, and some excellent results between the two cities by means of the Siemens' system. Batches of Italian or Swiss traffic perforated in London, are run through a Siemens transmitter here prefaced by a note that the next 40, 50, or 60 telegrams, as the case might be, are destined for re-transmission. Berlin then brings his re-perforator mechanism into circuit, a new tape is automatically perforated which is taken to the Zurich circuit where the entire series is run into Switzerland. Beyond this point there are, it is understood, not infrequently considerable line difficulties, but the transmission through German territory into Switzerland has recently repeatedly proved a very considerable improvement upon the normal route *via* France. Obviously the latter, when workable, is to be preferred, and is quite capable of carrying the traffic now that London has direct communication by Baudot to four Italian cities as a normal daily program. Unfortunately of late it has proved a program and very little more owing to the unsatisfactory condition of the lines aborad.

The staff wastage, the fret, the wear and the tear upon the telegraphists whose duty it is to manipulate under the conditions of intermittently interrupted lines is a phase of international working to which more attention should perhaps be given. It could be easily proved that the time taken to transmit telegrams under conditions such as the writer has in mind represent the face value of the telegram dealt with twice or three times over, while the operator's *average* gives but the poorest indication of the energy and patience expended. It is one of those cases where figures tell only part of the truth.

Opportunity has been afforded for perusal of a Siemens telegraphic development under the name of the *Pendelfeder*, which appears to be an off-shoot of the Siemens telegraph system proper, somewhat after the principle of the "stop-start" device followed up by the Western Electric in the application of their system to small subscribers or private renters. The mechanical portion is extremely ingenious.

Baudotistes in these islands are familiar with the term of "All up," which is an indication that synchronism has been lost, and that transmission is to cease temporarily. To the supervising staff the cry is by no means a comforting one, nevertheless, many have made the enquiry as to the origin of this technical phrase which appears to have no connexion with any portion of the apparatus. The explanation is simple. When the Baudot was first introduced into England the French instructor indicated by an upward movement of his hands that all the key telegraphists were to stop transmission. In imitation of the gesture all hands went up in the air, and the phrase "all hands up" soon followed. This was quickly reduced to "all up" and has so remained as a convenient form of warning and command.

A correspondent sends the following appreciation:

The C.T.O. lost a familar figure and an officer of wide experience when Mr. W. J. Bond took farewell of the office on July 10.

He entered the Service Sept. 4, 1875, and as was the custom in those days, was quickly in the midst of the fray, attending his first race meeting at Newmarket on completion of one year's service.

From that time onward his experience was a wide and varied one. At one time or another he has taken charge of every Division (except possibly the old F.G.), passing through all grades until reaching that position of dignity, Assistant Controller, Provincial.

He was in every sense of the word well known to all and had the ability to perform his official duties without losing sight of the fact that his associates of whatever rank were of the same human family. He retires with the goodwill of a large circle of colleagues and sincere wishes for a long period of good health in which to enjoy the pension earned by his lengthy service.

With 45½ years' service to his credit, Mr. Charles Faunch retired on his 60th birthday, Aug. 18. Starting from the bottom rung of the ladder he had to climb up by the slow stages of those days, of Third, Second and First Class Telegraphist before he could "get out of the rut." Promoted Overseer, 1897, it was nine years before the next stage, finally reaching the Superintendent Class A in 1918, and B the succeeding year. Our friend has thus served under five Controllers, viz., Messrs. Fischer, May, A. Eames, Newlands and Lee. Steady conscientious hard work has been the keynote of "Charlie's" official career added to which a kindly, cheerful disposition, made him one of the most charming of colleagues and the most tolerant of friends.

The London *Times* was good enough to publish the following appreciative paragraph:—

> Lord Northcliffe's speech before the Canadian Club at Vancouver came to us through the Imperial Cable in the short time of 45 minutes, which, in these days of telegraphic delay, is a great achievement for that service.
>
> The meeting of the Canadian Club in Vancouver was held at 1 o'clock in the afternoon—that is, 9 o'clock our time. A start was made with telegraphing the message at 2 o'clock (10 p.m. our time), and the full message was received in London at 10.45 (2.45 in Vancouver).

Digitized by Google

The deeply interesting account of the Imperial Wireless Station, at Leafield, Oxfordshire, by E. H. Shaughnessy, M.I.E.E., in the July number of the *P.O.E.E. Journal* provides much food for thought and not a little impetus to imagination. One cannot help throwing one's mind across the seas to the landing place of the first huge leap of the signal waves through space, *i.e.*, to Cairo.

What of the future of this untold wealth of possible means of communication when it is finally bridled, tuned, adapted, screened off from disturbances, and fitted with apparatus which shall soften into silence every half tone of unwanted vibration ? Who can tell ? Coming down to the practical side of actual facts the idea solidifies itself into one very serious thought of another nature. These power-houses, boiler, turbine, and condenser rooms, workshops, offices, turbo-generators, condensing plant, bungalows, aerial masts, &c., &c., representing thousands of pounds of capital expenditure, are all to concentrate their effort upon obtaining one single telegraphic channel, at most two, and the second channel means the erection and fitting up of another station at considerable cost. One's thoughts again turn to the ordinary submarine cable station from which it is possible to run quite a number of cables with at least two-channel circuits fitted to every cable core. With the possibilities which undoubtedly exist in wireless communications, common sense alone dictates that money should be spent on experiments but it is to be hoped that if all the hopes raised by fantastic newspaper articles are not fully realised the Government departments will not immediately be charged with the cry of "Waste" and "Wasters."

The Cable Room Annual Sports were held at the Grove Hotel, East Dulwich, on Aug. 5, and proved a complete success. The weather all but forgot to celebrate the occasion in the usual manner as it remained fine until the middle of the alfresco concert when it gave a sharp christening to the company and as suddenly altered its mind. The 1-mile walk handicap, won by Herrick (scratch), proved a tough contest, and the separate races for boys and girls were followed with the keenest interest by the onlookers and, needless to say, by the parents of the competitors. Whether it is strictly according to rule for an especially eager father to run in front of his progeny along the course with a tempting chocolate between his fingers no one seemed to question. However, it proved to be a consolation prize to the dear little toddler so the judges were not troubled ! A comic cricket match, Ladies *v.* Gents, which lasted under thirty minutes, provided an excellent link between tea and the concert, and resulted, according to the umpire, in the Ladies declaring with 548 runs for six ! As a visitor remarked, "Nothing has ever been seen like it at the Oval or Lords." It was not, however, very courageous of the sterner sex for the representative eleven to commit corporate suicide at the news !

Mrs. Wadley very kindly and gracefully presented the extremely handsome prizes. The Assistant-Controller, on behalf of his wife, thanked the staff for their appreciation of Mrs. Wadley's services, and the presentation of a gold watch, chain and compass pendant was then made by Mr. H. J. Broughton to the much respected Mr. C. F. Moody, Asistant Superintendent.

Mr. Broughton's speech was brief but struck the right note when he said : "What is the reason for the absolute unanimity with which Mr. Moody has been loved and respected in the Cable Room ? The answer was given me by one of the cable room staff and I believe it to be the right one. Mr Moody has always proved a white man." Musical honours followed, after which the pensioned recipient thanked all for their co-operation during his years of service, in a truly characteristic speech. An excellent concert and a few dances brought to a close "one of the happiest family gatherings." Naturally the Bon Accord Orchestra under the usual high standard maintained by Mr. Leonard Coombs, co-operated unfailingly.

The Times states that "every private wireless station in France is to be taxed to the extent of 10 francs. Even receiving sets put together for a few shillings by schoolboys are included in the category of 'stations.'" This is not so exacting as it may appear. Some of the "schoolboy" sets put together for a few shillings have given excellent results and the technical schools of France make it possible for any interested and enterprising youngster to manufacture his own set at a comparatively fractional cost of the same or even inferior quality article pieced together by expert vendors. The writer has listened in on schoolboy sets in this country with surprising results. The youth of our own Service has taken wireless with extreme seriousness. It is no secret that in some cases it is even alleged that better results are at times obtained on certain amateur sets than upon regulation installations.

It may prove one of the drawbacks of wireless that, owing to its availability to everyone, the secrecy of the telegram is no longer inviolate, while Scotch whisky is smuggled into America by vessels fitted with private wireless sets which are thus able to communicate with their confederates on shore and befool the Customs.

Reuter's Trade Service announces that, according to the *Lokalanzeiger* Berlin, the German postal authorities and the representatives of the Mackay Co. are still negotiating for the laying of a direct submarine telegraph cable between Germany and the United States. Similar concessions are being requested by the Western Union and Commercial Cable Companies. It is also stated that certain American Companies (two at least) have plans ready for an American wireless station in Germany.

On Aug. 4, Prince Luthumirski, Polish Minister in the United States, signed a contract between the Polish Government and the Radio Corporation of the U.S.A. for the erection of a wireless station in Poland to cost three-quarters of a million sterling in order to obtain direct communication between Poland and the U.S.A.

As an indication of the tendency towards automatic transmission applied to the Baudot system, it is interesting to note that, according to *The Electrical Review*, "an order has been made restoring Patent 1902 of 1910, granted to Jules Carpentier for an improved transmitter for transmitting telegrams composed in perforations on a band by the Baudot system."

A correspondent of the *Morning Post* at Copenhagen recently stated that there is good possibility of the re-opening of telegraphic communication with Russia, *via* the Great Northern Telegraph Co.'s system in the near future. It is said that all the telegraph apparatus in the Petrograd office is intact and that the offices served by the land lines *via* Irkutsk and Vladivostock are in a position to re-open communication between Europe and Eastern Asia.

In the July number of the *Journal Telegraphique*, Berne, Mr. G. B. Serra, Engineer of the Institute of Posts and Telegraphs of Italy, continues his informative articles on the Italian system of Telegraph and Telephone Aerial line construction.

It is, therefore, evidently not due to any lack of competent students of telegraph construction theory if telegraph communication with our much respected Italian friends leaves much to be desired.

Many have been the queries raised as to the author of those specially appropriate lines quoted by the Postmaster-General, when he unveiled the C.T.O. Memorial Tablet to the Memory of our Fallen Ones. The Quatrain will, doubtless, be recalled by everyone who was then present.

"On Fame's eternal camping ground
Their silent tents are spread,
And glory guards with solemn round
The Bivouac of the Dead."

Thanks to the journalistic courtesy of the editor of *John o' London's Weekly*, enquirers are informed that "they are the last four lines of the first verse of "The Bivouac of the Dead," by Theodore O'Hara in R. J. Kelly's Popular and Patriotic Poety, published by the Catholic Truth Society of Dublin, part I. The entire poem may be purchased for the price of one penny.

We are informed that about the middle of August the Western Union Telegraph Co. sold $15,000,000 15-year 6½ Bonds. They were offered to the public and sold at 99 within a few hours.

The laying of three new cables, Tangier to Oran, Casablanca to Oran, and Casablanca to Tangier respectively, was completed last month.

HOW TO LEARN THE MORSE CODE IN TEN MINUTES.

BY MR. TALMAN.

(Reproduced by kind permission from *Allan Glen's Magazine*, Glasgow.)

I MAY as well disarm criticism at the outset. I am inexpert in signalling. I was born before the Boy Scouts, and I could not, even to save my life, fit up an ordinary electric bell. I have never sent a message by heliograph or by flag-wagging, nor have I on any occasion tapped out the plan of escape to the prisoner in the cell next to mine. I have sent a few telegrams in my time, but never one without paying for it. With these credentials, and scorning the injunction that bids the cobbler stick to his last, I proceed to expound a new and simple method of learning the Morse code.

Ten minutes is all the time you need give to the study of this method. After one sitting you will be able to transmit messages with quite remarkable speed and accuracy, and though you will not at once be able to decipher other people's messages, there is another simple method of learning to "take off" from someone else sending.

Those of you who are expert signallers will, of course, give the superior sniff and say that this is impossible. You know the grind you had in mastering the dot-dash mystery, and you know that even after many days you had strange lapses of memory which made you forget the signal for this letter or for that. So you value your now assured command of the code highly, just in proportion to the difficulty you had in acquiring that command. Perhaps you are right. Many of your elders, at least, follow the same rule, and lay stress on the "mental discipline" involved in a study, even although the practical end achieved may show little to justify the labour of it. A short and easy method is often suspect, no matter how efficient it may be.

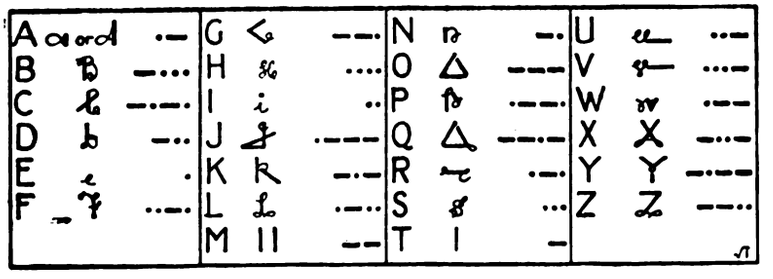
Now I frankly confess to a suspicion that much of the talk about the mental discipline of studies is here humbug. All real study is a mental

Digitized by Google

discipline. And for my part I prefer the mind that is avid of accurate knowledge of all kinds, and seeks it by the shortest and most direct routes. The more we economise in time and effort in our search for knowledge, the more fully will our minds be stocked, and the more varied and real will be the discipline we have undergone. Away with cant! We learn the spelling of words and the rules of arithmetic as things of practical value, not as a solemn gymnastic to make us good citizens, voting wisely and avoiding the police.

"But," someone may say, "I don't want to learn the Morse code. Perhaps I won't ever have occasion to need it." Perhaps you may not. But I know that if I saw a chance of getting at the cost of ten minutes' study a scrap of knowledge that other fellows didn't grudge spending hours and days in mastering, I would be off at once to the Bank of Time to draw out that ten minutes.

This brings me back to my title; (and please don't tell me the ten minutes are already up, for they are not begun yet). It was many years ago that I devised the scheme I am about to describe. The germ of it came to me, I am sorry to confess, during an examination when I was a school-boy. We had been discussing beforehand secret codes of communication (such is the divine foolishness of boys), but we were too ambitious, too subtle, too boyish to see that all the exam. would be taken up with signalling, and no one would have time to attend to the detail of writing. It was a grand idea! We had elaborate cypher codes, cryptograms and devices that would make a modern spirit-wallah ache with envy—but, alas, they all needed a key to interpret them, and even then the signalling code had to be devised. Morse we tried to study. The honest effort we wasted on that would, if properly directed, have given us all a hundred per cent. in every subject. But it was futile. Scientific and analytical methods applied to a grossly unscientific code left us in the air. We gave it up. Morse was all grind without any system. Euclid was easier.



In revealing to the world this shameful secret I may be accused of corrupting young minds and turning staid examination rooms into frivolous table-rapping seances; but I hasten to rebut that accusation. What with Mr. M'Quistan's new wireless installation and an enthusiastic and growing group of signalling experts in the corps, one feels that the masters ought to be protected from the diabolical ingenuity of the schoolboys. It is to arm my innocent fellows of the staff as well as to assist the boys that I now disclose my wonderful system of memorising Morse.

In the accompanying table you will find all the letters of the alphabet drawn out in block capitals, each letter accompanied by a special script form and also by its Morse equivalent. All you need do is copy and study the script forms carefully. They are all variants of standard forms of alphabet, some capitals, some small letters. In the script forms loops and straight strokes are made use of in such a way that the loops stand for dots and the straight lines stand for dashes. Try it and see for yourself. Write down the grotesque Z, for example—two straight lines and two loops, *i.e.*, dash — dash — dot — dot. The order in which the loops and lines come in writing the script is the order for the dots and dashes.

There is no difficulty about any of the letters, except, perhaps, I, S. and O. In I the dot of the written letter stands for one of the dots of the Morse symbol; while in S (made as shown) there are three loops, equivalent to the three dots. Study this form closely. The triangle for O is not so unsatisfactory as it may seem, for if any young hyper-mathematician complains that a triangle is not equivalent to a circle, I would point out that the circle is just a special case of the triangle, with two sides missing and the third side bent round. Then think how beautifully Q follows from O!

Now for your ten minutes' course. Since the eye can picture the shape of a letter more readily than the mind can recall an arbitrary arrangement of dots and dashes, you must get the script forms clear to the eye. Write out the script alphabet carefully as often as you can during ten minutes. Do nothing else. Forget dots and dashes, and memorise the forms, paying strict attention to the order of the loops and straight lines. J, for instance, commences with the loop; Q's first move is down the left leg, then along the base to form the loop and turn upwards; X may begin with either leg, but must be written without lifting the hand, and end with an upward line.

At the end of ten minutes put away the diagram and dot-dash any message you care to compose. If you cannot transmit eight words a minute correctly and keep it up, you are below the average in intelligence. So there's a test!

LONDON ENGINEERING DISTRICT NOTES.

IN terminating his service with the Department at the end of July, Mr. Moir addressed the following letter of thanks to the staff:—

> "In saying good-bye to the staff of the London Engineering District I should like to express my appreciation of the loyal and efficient service which they have rendered during my lengthy term of office as Superintending Engineer.
>
> In war time and in peace time alike, the staff have consistently sought to maintain and uphold a standard of work and effort worthy of the Metropolitan District.
>
> My memories of the District will always be very agreeable, and I hope that all the members of it may have a successful future."

It is gratifying to know that the efforts of the staff were appreciated by one who never spared himself in the interests of the Service.

"The King is Dead—Long Live the King."

Mr. Mellroy the new head of the London Engineering District comes with an established reputation. He will find the staff which he will in future control prepared to uphold the credit of the District in the time to come as in the past. The nation appears to be settling down at last to serious work and if this temper continues the demand for telephone service, that vital necessity of business, should be enormous. Much has already been done to overtake the arrears of construction, but much still remains to be done. Unfortunately the Engineering Department is largely dependent on builders and electrical contractors, but the difficulties which these have encountered in the past should soon disappear and a pre-war rate of delivery be established.

The cry is full steam ahead, and the slogan—one telephone per head of population.

Things are not what they seem.

Reference was made in a previous issue to a little crop of complaints from the public concerning Post Office workmen who at times appear to be idling The facts have been stated but as the public cannot always appreciate facts the question arises whether recourse should be had to a little innocent camouflage. For instance, the members of a gang during the short periods when they cannot be given active employment might go through the motions of say pulling a cable through a pipe. Everyone who has had anything to do with the Army will know what going through the motions means. There might, of course, be a danger of the men breaking into a hornpipe if one of the numerous ex-service bands started playing in the neighbourhood. The men have already had some experience in going through the motions through having to empty a manhole of foul air by lowering a bucket into it several times and emptying the contents into the gutter. Members of the public watching this operation probably tell their friends how they have witnessed another awful example of Government waste—a man actually pretending to bale water out of a hole and bringing an empty bucket up each time. As an example of the spirit of unreasonableness abroad the case of a subscriber who made a recent complaint may be quoted. The gravamen was that the fitter had taken too long to do his work. An explanation was called for and duly furnished by the fitter who stated that he was continually interrupted by the subscriber who stood by him with a watch in his hand. The fitter further stated that the time taken to do the work was 2 hours 49 minutes *including the time spent in listening to lectures on the telephone system.*"

Help Wanted.

Whilst it is not contended that historical matter connected with the development of the telephone can yet kindle the same enthusiasm and interest as say, the remains of a Roman aquaduct or a Celtic rath, one must remember that this will not be so after the lapse of centuries or even years. Would that our predecessors in the engineeeing line had kept this in view.

Some days since the writer in strolling over one of the Surrey Commons ran across an old windmill, which on inspection proved of unique interest to one keen on machinery. The old mill contained excellent examples of wooden gearing, an interesting if somewhat crude form of windmill governor, anent which a long controversy might be raised as to who first applied the "lift tenter." Some say Captain Hooper of Margate, others again that it was old Meikle, the Scottish millwright, but then the Scots claim most things. Incidentally this old mill, according to local information ceased to work some 30 years since and unless something is done to preserve it, will cease to exist 30 years hence. Meanwhile such examples of archaic engineering are to be found throughout the length and breadth of the country. For instance, one could cite the remains still extant, though rapidly disappearing of the Sussex iron industry. In this case the astonishing thing is that although the industry only ceased to exist about a century since, the remains and histories of the various furnaces are very meagre indeed.

To come back to telephones, it may interest readers of this column to know that one of our late colleagues, Mr. F. G. C. Baldwin, now Assistant Superintending Engineer, Newcastle-on-Tyne, is writing a history of telephony

Digitized by Google

in Great Britain, dealing particularly with the technical side. The writer believes that Mr. Baldwin has had the project in mind for some time but possibly he has been stimulated by reading the account and transactions of the recently formed Newcomen Society, a society founded to unearth records and discuss matters of historical interest in connexion with engineering generally. Hitherto it must be admitted that the history of engineering has been, to say the least of it, somewhat neglected by engineers generally. We are so busy keeping our eyes on the present and future that we are apt to overlook the past, but it is well even from a strictly utilitarian point of view, that we should appreciate what has been done by our predecessors. One's interests cannot but be stimulated by learning something of the ingenuity and characters of engineers of bygone days. Meanwhile Mr. Baldwin will be glad to receive from anyone either photographs or drawings of historic interest in connexion with telephone plant or apparatus and he undertakes to return photos, negatives or sketches if desired. Needless to state he will take great care of them.

OPEN LETTER TO A TELEPHONE SUBSCRIBER.

ALTHOUGH you have been called upon to pay increased charges for your telephone line and naturally feel aggrieved, do not make a hasty decision that because of this, you will curtail your telephone facilities, or cease altogether your service.

As a business man, presumably you have not in the past increased the number of lines rented without due regard to the needs of your business or, as a householder, rented a line without being satisfied that one was needed.

Have you ever considered the telephone in relation to the saving of office expenses and to business ?

If the telephone had not been invented, think of the heavy expenditure you would have now to incur by the employment of personnel to carry messages from department to department, from branch office to branch office, to and from your clients or by the use of the telegraph. The telephone is a remarkable time saver, a fact which you have no doubt overlooked because of its every day use. On extension lines between your departments, the time value must repay the cost manyfold, because your staff lose little time in communicating with each other . Labour costs are much heavier than telephone costs.

If you curtail your telephone facilities have you considered that business may be lost because your lines may be reported engaged and an order taken by a competitor ? Have you calculated the saving in travelling expenses which the use of the telephone has saved for so many years ?

As a shopkeeper you are also being called upon to pay increased charges. What is the value of the telephone to you, and can you afford to dispense with it without affecting your business ? I think not. The telephone leads to additional business. Your customers order their requirements from you, whereas if you had no telephone they would obtain their goods from the nearest depot. You can obtain extra stock without delay from your suppliers. By the aid of the telephone you can obtain competitive prices from the wholesale markets and thereby save working time and travelling expenses. Your name and address is printed free of charge in the Telephone Directory which is, in effect, a cheap but valuable advertisement. It is known that large repeat orders have often been obtained in this way.

As a householder, think well before you give up your telephone. It is an insurance against fire and burglary. It may repay the cost a hundredfold if a doctor can be summoned at once in case of serious illness. Your wife or housekeeper can place her household orders without leaving the house. You save travelling expenses. You can communicate at any time with business or private friends after office hours. You can communicate with any other telephone subscriber in the country. You can arrange hotel accommodation immediately if called upon to travel unexpectedly.

Think well, therefore, before depriving yourself of the advantage of the telephone ; even at the enhanced charges it is the cheapest proposition in the market, and direct saving of the cost of the service may result in indirect losses in many ways.

LONDON TELEPHONE SERVICE NOTES.

Presentation to Miss Heap, I.S.O.

REFERENCE to this function at greater length than would entitle it to be included under the heading "Notes" appears elsewhere in this issue. To say that the ceremony was a success is to give it faint praise, and the Committee responsible for its arrangement are to be heartily congratulated. The stately old Hall of the Stationer's Company provided a splendid setting and the pleasures of the reunion with former colleagues helped to drive away the sadness felt at the loss all in the telephone service sustain on Miss Heap's retirement.

* * *

Presentation to Mr. A. Moir, O.B.E.

Some indication of the regard in which Mr. Moir was held by all who worked with him can be obtained from the fact that no less than 3 presentations were made to him on his retirement. The last but not the least in the warmth of its well wishing took place in Mr. Preston's room at the G.P.O. South one morning during the closing week of July. Mr. Moir came into personal touch with many members of the L.T.S. and it was their united wish that he should carry away with him some token of their regard for his sterling merits. To this end they had purchased for him two Dunhill pipes in case, a pouch to make the most eclectic envious, and a Swan self-filling fountain pen. Mr. Preston, who has a reputation for doing these things admirably, said something of the happy relations between the Superintending Engineer's staff and his own, and attributed this condition of things largely to Mr. Moir's personal example. Several others present reinforced Mr. Preston's record, making it clear that even amongst Scotsmen and Engineers Mr. Moir was a towering figure, and thereafter Mr. Preston made the presentation. Mr. Moir replied in happy vein and departed after much vigorous handshaking, promising that the gifts of the L.T.S. should be his constant companions in his most pleasant hours.

* * *

London Contract Branch.

As is well known certain subscribers would not sign a new agreement under the Revision of Rates and their circuits were subsequently disconnected. Contract Officers called prior to the recovery of the apparatus and it is interesting to note that some 30 per cent. of these circuits were not lost to the service as the subscribers were either induced to sign the agreement or new subscribers were at once obtained to replace them.

The argument that a call by a Contract Officer in such cases would produce good results—although doubted in some quarters—has been handsomely vindicated.

It is found that quite a number of subscribers or rather late subscribers who allowed the installation to be recovered have already found that telephone service is quite indispensable and have asked to be reconnected. As the stagnation in trade and the holiday season come to an end it is anticipated that many more will have the service re-instated. While funds do not run to "fatted calves," nevertheless the prodigals will receive quite a hearty welcome.

* * *

London Telephonists' Society.

Mr. M. C. Pink has the distinction and good fortune to be the thirteenth president of the Society. It is only those who deny themselves indulgence in matters of chance who persist in the superstition that ill-luck is associated with number 13. The thirteenth session of the Society promises to be a very successful one. The presidential address takes place on Wednesday, Oct. 5, the subject being "The future development of the Telephone Service." Subsequent items in the programme of the session are :—

Nov. 1.—Debate.
"Has the telephone added to the sum of human happiness ?"
Affirmative, Mr. H. Dive.
Negative, Mr. H. G. Corner.

Nov. 30.—A paper by Miss A. C. West, L.R.A.M. (Eloc.).
"The voice and its effect on the Telephone Service."

Dec. 31.—New Year's Eve Dance.

Feb. 8, 1922.—Competition papers.

March 8, 1922.—Competition Essays.

* * *

London Telephone Service Swimming Association.

The Association is holding a Grand Water Gala at Great Smith Street Bath, Westminster, on Friday, Oct. 7, at 7 p.m.

The principal events include :—

Team Race for the Pound's Challenge Cup.
Championship of L.T.S.
Diving Competition.
Traffic Officers' Race.
Open Handicap for Supervisors.
Open Handicap for L.T.S.
Learners' Race.
Lantern Race.
Polo Match.

Much enthusiasm is being shown and some really good work is being put in by those who mean to compete.

You are recommended to book your seat early, as the indications are that the demand will far surpass that of last year.

Digitized by Google

Tickets (Numbered and Reserved 2*s.* 4*d.*, Unreserved 1*s.* 3*d.*) may be obtained from the Association members as under:—

Avenue	Miss Mason
Central	Miss Milbank
City	Miss Condon
Dalston	Miss C. Phillips
Clerkenwell	Miss Brain
East	Miss Brinsden
Gerrard	Miss H. Davis
Hampstead	Miss Lander
Hammersmith	Miss Campbell
Kensington and Western ...	Miss Penny
London Wall	Miss V. Young
Museum	Miss L. Haines
Mayfair	Miss Neile
Park	Miss Hawkins
Regent	Miss Brimsgrove
Trunk	Miss Hodder
Victoria	Miss Hill

or of Miss Temme, (Hon. Sec.) Trunk Exchange.

Gerrard Exchange.

We are feeling very proud of Miss M. M. U. Fitzpatrick and Miss A. M. Alston (Gerrard Telephonists) who were awarded 1st and 2nd prizes respectively in the *Daily Sketch* dancing competition at Douglas, Isle of Man, in August. There were 1,500 entrants, so that the winning of the beautiful silver cup by Miss Fitzpatrick was something of a triumph for London.

* * *

Civil Service Lifeboat Fund.

This year's collection for the fund has just been completed and has secured the gratifying sum of £105 10*s.* which is £33 9*s.* in excess of the sum contributed by the London Telephone Service last year.

* * *

A Wedding.

Every month we publish a list of women who leave the L.T.S. on account of marriage, but seldom do we record the change from the single to the married state of the men of our Department. That step has recently been taken by Mr. Hubert C. S. Evans, a well-known member of the staff of the Controller's Office who came over from the late National Telephone Company. His colleagues presented him with a gift of cutlery as an outward expression of their good wishes.

* * *

Belgrave Social and Athletic Club.

A successful river trip took place on July 24th starting from Richmond at 11 a.m., the members had an enjoyable four hours on the water and on reaching Walton-on-Thames, spent a couple of hours ashore searching for ices, etc. Returning at 5 p.m. prompt (as the members who had an extra ice, and "lost the post" know full well) we concluded the day's enjoyment at Richmond at 8.30 p.m. Excellent luncheon and tea were served on board, and with the kind help of various pianists and vocalists and with the cameras on overtime, we add the second item to our list of successful summer outings. Our useful "rag cat" was once more raffled, realising the sum of 25*s.* which has been forwarded to the London Hospital.

We have another char-a-banc outing arranged for Oct. 2 to Windsor, and the ticket will include first class luncheon and tea. All further particulars can be obtained from the Secretary, Miss Williams of North Exchange, who will also be pleased to give information to any of the staff who are interested in the club.

PRESENTATION TO MISS A. A. HEAP, I.S.O.

ALL roads seemed to lead to the Stationer's Hall on the evening of Friday, July 22, and anyone familiar with the personnel of the London Telephone Exchanges who happened to be in the neighbourhood of Amen Corner at 6 of the clock that evening would have found him or herself under an obligation to bow almost as exhausting as that experienced by a crowned head during a royal progress. If there was an exchange unrepresented it must have been that in which the sole caretaker operator had failed to secure a substitute. Several exchanges counted their representatives by the score, and the company which had assembled to do honour to Miss Heap included many an ex-telephonist or ex-supervisor whose matrimonial responsibilities had failed to dull their memories of their former Superintendent.

It was a crowded house, and as Miss Heap was met by Mr. Preston she was greeted by burst after burst of cheering, renewed again and again as they proceeded in company to the centre apartment where the latest telephonist recruit—Miss Dick, of the City Exchange,—presented a bouquet of pink malmaisons. Miss Heap then received the guests, and for each she had some little personal greeting or joyous quip. Refreshments were served in the dining hall which, it has to be admitted, is immeasurably finer than the most lavishly decorated of exchange dining rooms. No doubt the Stationers' Company is not yet nationalised and can therefore be certified as free from anything in the nature of unnecessary expenditure—(would that the exchange dining rooms might meet a like fate). At 7.30 p.m. the sounds of the Orchestra, which had kept one's feet itching, were stilled and Mr. Preston opened the more formal part of the proceedings by calling upon Miss A. E. Cox to address the gathering. Miss Cox made a bright and happy speech full of amusing anecdote, and justly deserved praise. She was followed by Miss Newman, who was no less happy in her account of the hopes and fears that beset her in the fateful "transfer" days of 1912 when a first hand acquaintance with Miss Heap fulfilled all her hopes and banished all her fears. She finished with a quotation from an early Superintendent of Buildings, one with a great reputation for wisdom in which he asserts that "he who worketh with diligence shall stand before Kings." This was understood to be graceful reference to Miss Heap's curtsey when receiving the Imperial Service Order and was greeted with acclamation. The Chairman then called on Miss Liddiard, who had pleaded to be allowed to add her tribute to the work of Miss Heap and a noble tribute it was. Thr Assistant Controller Mr. J. F. Edmonds, then added his testimony to Miss Heap's whole-hearted devotion to her duties, and if one had some difficulty in appreciating the precise application of the story of the cook's choice of hymn it is probably due to one's limited knowledge of Miss Heap's circle of acquaintance amongst the forces of law and order. Mr. Edmonds was followed by Mr. Kidner, Assistant Secretary in charge of the Telephone Branch of the Secretary's Office, who made jealous many a member of the Traffic staff of the L.T.S., as he described how Miss Heap was known to him by reputation even before he assumed his present responsibilities in the field of telephones. After Miss Webb had read messages from Colonel Sir Andrew Ogilvie, Mr. John Lee and others expressing regret at their inability to be present, Mr. Preston entertained the audience with some reminiscences of the earlier days of the P.O. Telephone Service in London with their indelible imprint of Miss Heap. He finished with an earnest and well deserved acknowledgment of all that she had accomplished on behalf of the women of the London Telephone Service. He then handed to Miss Heap a single stone diamond ring, a banker's draft for £100 and an album containing the signatures of those contributing and numbering between two and three thousand.

Miss Heap replied in a speech full of kindly wit, sound advice and appreciative acknowledgment of this latest tribute from those who had learned to regard her and whom she regarded with feelings of a very warm and loving character. It is difficult to realise that Miss Heap has gone—possibly because her successor has not yet been proclaimed—but as the realisation comes to each and everyone, they think of her in terms which can best be summarised in a quotation from Richard II. that with her it shall be the case that—

> "Each day still better other's happiness,
> Until the heavens, envying earth's good hap,
> Add an immortal title to your crown."

EFFECTIVE METHOD OF PRESENTING "A" OPERATOR "BREAKING IN" on ORDER WIRE.

Digitized by Google

THE BAUDOT.—XXIV.

BY J. J. T.

WE now come to the *moderator* (Figs. LXVII, LXVIII) which maintains the receiver at a "running speed slightly higher than that of the distributor which from Rings 3 and 6 automatically transmits a checking or braking current from a local battery of 40 volts" as mentioned in Article XXI. It is made up, broadly speaking, of two parts. Number one is a simple octagonal metal block W (Figs. LXVII, LXVIII) through which are drilled two holes permitting of the passage of a pair of guiding rods RR'. To each of the opposite sides *a*, *a*' is fitted a small screw pin upon which the looped ends of the steel spiral springs S, S' are respectively hooked. The block W is capable of sliding easily up and down the rods RR. T is a thin flat spring screwed to W, and fitted with a tow brake at its free end. When the moderator is placed in position on the receiver axle A', which latter extends rearwards beyond the receiver casing for this purpose the tow brake of T comes into contact with the polished surface of a brass saucer C (Fig. LXVII), as the centrifugal force developed throws out the block W along the guiding rods RR'. By means of a

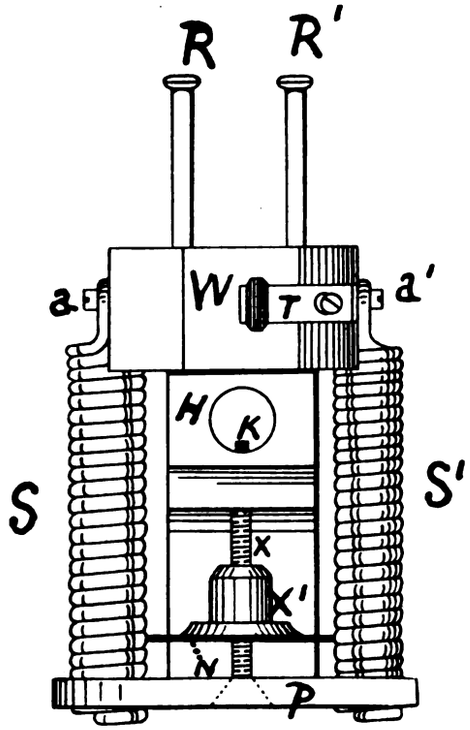


FIG. LXVIII.

notched screw L (Fig. LXVII) the entire moderator may be fixed in varied positions on the extension A'' of the axle A'. Thus the nearer the moderator approaches the saucer C the sooner will the tow brake commence its braking effect and the greater the distance between the brake and C the later will be the action of the brake as the centrifugal force developed will in the extreme case need to be sufficient to move W out to a point along RR' opposite the outer edge of C. What may be termed the fixed portion of the moderator consists of a metal block H (Fig. LXVII) through the centre of which is drilled a hole sufficiently large to fit on to the axle extension A''. A narrow groove is cut along A'' parallel to its length and into this groove slides the catch K when the moderator is pressed along A'' into position. This device, therefore, holds the moderator firmly upon A'', during rotation, the screw L maintaining it in its longitudinal position upon the same as already mentioned. Into the upper side of the block H are firmly fitted the guiding rods RR' along which W. moves so that when the moderator is at rest the tension of the springs SS' acting upon W at one end and a flat steel spring tension-piece N at the other (the ends of which are thrust between two of the spirals

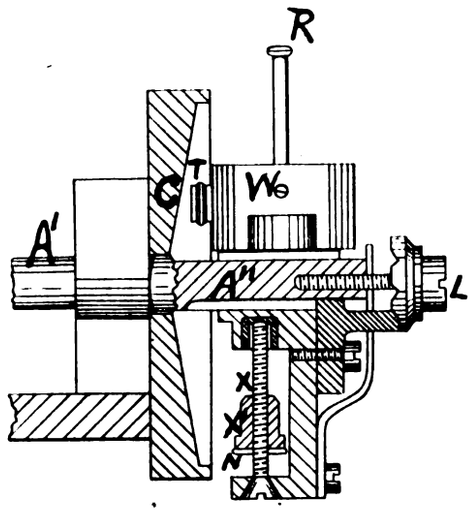

FIG. LXVII.

of their respective springs), the block W is brought to rest against the upper side of the block H. A long screw X carries the tension-piece N and the cross bar P at one end, and at the other is screwed into the under side of H. X' serves as a metal sliding-block or guide to the tension-piece N. In practice no adjustment of this latter need be made. The small adjustments of speed necessary are to be obtained by unhooking the springs S, S' from their respective pins *a*, *a*', and adjusting their length, holding the looped end of the springs and screwing each (one-half convolution at a time) *into* the cross-bar P, so that a lesser number of convolutions become active on the tension-piece N, *i.e.*, the tension increases and with the tension the speed.

The process should of course be reversed if it be desired to decrease speed. The complete adjustment of the receiver speed, therefore, comprises: (1) the correct number of spirals of the moderator in play so as to give a slightly higher number of revolutions than that of the distributor brushes; (2) the correct distance of the moderator on A'' from the saucer C, so that the braking effect is neither too abrupt or too weak; (3) a similar fineness of adjustment of the electro-magnet brake B in relation to the brake wheel BW (Fig. LXV).

(To be continued.)

SPANNER IN COW'S STOMACH.

A piece of telephone wire which had penetrated its heart and an iron spanner in its stomach were some of the discoveries made by a post-mortem examination of a cow at Hathersage, Derbyshire, which had been unaccountably ill.

It is thought that the spanner had been used by men repairing the local telephones.—*Daily News.*

A cow there was, in bovine rage,
That turned from grass and thyme and sage,
And in her ire
Eat with some wire,
A spanner down at Hathersage. D. S. A.

REVIEWS.

"*The Henley Telegraph,*" organ of W. T. Henley's Telegraph Works Co., Ltd., and of which we have seen an odd number or two, without doubt, contains many articles of interest, not only to those immediately concerned with the progress and welfare of the firm but to others outside that restricted *clientele*.

"*Appareils et Installations Télégraphiques.*" *Par E. Montoriol Inspecteur des Postes et Télégraphes, Professeur à l'école Superieure des Postes et Télégraphes, Paris.*

This admirable work of over six hundred pages with its modest preface by M. Blondel, published by the well-known firm of Baillière et fils, as one of the many useful volumes of the Encyclopédie d'Electricité Industrielle is a pleasure to review. The type, the paper, the sketches and the diagrams are excellent. As one would expect from the pen of M. Montoriol, the writer has handled his subject in a masterly manner, and with his usual thoroughness. The book apparently is also to form part of the *Bibliothèque des Annales des Postes-Télégraphes-Telephones* and is "specially devoted to apparatus of French construction." While this latter aim has been well and consistently kept in view throughout the volume, there is no neglect of foreign apparatus, and generous tribute is accorded to the labours of telegraph engineers of other lands. Mere mention of a few of the names to which M. Montoriol refers from time to time are sufficient proof of the authors catholicity in this direction. Heaviside, Pupin, Vaschy, Morse, Barbarat, Varley, Wheatstone, Creed, Picard, Mercadier, Van-Rysselberg, Dejongh, Muirhead, Baudot, Pollak-Virag, Murray, Belz, Hughes, Brahic, Siemens, the British Post Office, Western Union, and Western Electric are all brought into the picture to obtain a correct historic perspective. Automatic transmission by the Wheatstone system alone occupies eighteen pages, and over seventy are devoted to Hughes apparatus for example. Although both Murray and Siemens' high speed systems are dismissed with but very few words, he has found space to refer to Siemens' and Halske's Telescripteur, the Telewriter, the Telephotographic system of Korn and Bellin, the Telautograph of Jordery, Wheatstone's A B C, and to Thompson's mirror and siphon recorder, devoting an equal number of pages to Carpentier's *enregistreur à siphon*, an ingenious modification of the former's apparatus, more suitable for the working of relatively short submarine cables. The P.O. standard relay has due attention, together with the modified form of Baudot relay (1915) which at that date applied the "carriage" adjustment to the French relay.

The Baudot, quite naturally, has pride of place in this volume, and itself forms a work of reference on this well-known and widely-used system.

On page 274, M. Montoriol has a good word to say for the phonic wheel with the reserve that, "*il n'est pas aussi parfait que le regulateur Baudot*" though frankly admitting that it is sufficiently so and that there is a decided advantage in being able to change the speed without stopping the distributor especially in view of the approaching possibilities of automatic transmission.

One particularly interesting item of information appears on pp. 348-9. It is with reference to the abandonment of the "double" and "triple" types of forked Baudot decided upon by the French Administration in the near future. The writer says:—"*Les installations doubles et triples échelonnées sont appelées à disparaitre dans un avenir assez prochain; en effet, dans un but d'unification du materiel, l'Administration a décidé de les ramener toutes au type quadruple, quitte à n'utiliser que le nombre de secteurs strictement necessaires.*"

Duplex (differential and bridge), diplex, simultaneous telegraphy and telephony, are all dealt with as far as the restrictions of space would necessarily permit in the case of a work of this kind.

Batteries, primaries and secondaries with the regulations for their maintenance and the arrangements for the distribution of their power as fixed by the French Administration are variously dealt with together with a very good description of the Western Union Dynamo-electric system of supply. The utilisation of the C.B. system in French offices has due attention, while a table of "Hourly Outputs" of the various telegraph systems, according to French calculations and experience, proves an interesting item upon which, however, there will possibly be some disagreement outside of French territory.

For page-printing telegraphy, M. Montoriol has no use and sees no justification of expenditure. In this, as our readers know, he is not alone. He is, however, insistent upon the advantages of Baudot retransmitters and says prophetically that "on the day when lines are constructed completely immune from exterior perturbations, if we will, we may have direct Baudot communications such as Paris-Saigon or Paris-Vladivostock at the same speed, *i.e.*, 180 r.p.m." We hope one day to have unperturbed wires to Lyons, Milan, Zurich, &c., &c., then may your prophesy prove true, *cher collegue*!

J. J. T.

SELECT COMMITTEE ON THE TELEPHONE SERVICE.

RESUME OF EVIDENCE (*continued*).

Mr. T. H. RYLAND was examined on behalf of the Farmers' Union on *July* 18. He thought that more extensive propaganda of the rural rate was required. He said that farmers disliked party lines, and thought they should be provided with direct lines, the service being established independent of the cost. He referred to the high rural development of Canada and the United States where galvanised iron wire was generally used instead of copper wire.

Mr. Ross JOHNSON (Bristol Chamber of Commerce) was next heard (*July* 20). He desired that Avonmouth should be included in the Bristol area. He was of opinion that the proposed charges would result in a smaller use of the service and defeat their purpose, but agreed that the service must be self-supporting.

The next witness (*July* 27) was Mr. W. B. PINCHING of the Post Office Engineering Factories. He described the class of work performed at the various factories, and suggested that the staff ought to be transferred from the control of the Stores Dept., to that of the Engineer-in-Chief. He thought that research and experimental work would be more effective if carried out at the factories, but that the manufacture of plant was best left to outside firms.

Sir D. M. STEVENSON, formerly Chairman of the Glasgow Corporation Telephone Service, also gave evidence. He gave information of the development of Glasgow during the period of competition. He quoted some pre-war Danish rates, and some Norwegian figures which were not up-to-date. He thought the present British charges ridiculously excessive, and thought the Glasgow Corporation could provide unlimited service for £13 6*s.* 8*d.*

The Committee is adjourned, and proposes to publish the evidence together with an interim report.

OBITUARY.

THE LATE MR. J. P. HASLEM.

Mr. Haslem, Clerical Officer, Traffic Branch, P.O. Telephones District Manager's Office, Victoria Street, Blackburn, died on Sunday, July 31 1921, after about a week's illness. The funeral took place at Tonge Moor, Bolton, on Wednesday, Aug. 3, 1921. He was a member of the Bolton Staff and came to Blackburn on the amalgamation of the two districts in 1916, and was very much respected throughout the district.

„ 7.—L.T.S. Swimming Association. Grand Water Gala, Great Smith Street Bath, Westminster, 7 p.m.

G.P.O. ARTS CLUB.

EXHIBITION ANNOUNCEMENT.

ARRANGEMENTS are in hand for holding an Exhibition at Mount Pleasant Post Office, London in October next.

The Exhibition will consist of original Paintings, Drawings, Etchings, and Pictorial Photographs, Art Needlework, Metalwork, Jewellery, and other Works of Art of original design by members of the Club.

Officers of all Departments desirous of participating are invited to forward a stamped addressed envelope for particulars of membership and members are requested to send their present addresses to the Hon. Sec., Chas. U. Cooke, 369, Essex Road, London, N.1.

The Club was founded in 1906 for the purpose of encouraging the production of Works of Art by officers in all grades and department of the Postal and allied services. Annual exhibitions, monthly meetings, competitions, sketching excursions, practical working demonstrations, &c., were held successfully until the abnormal conditions prevailing in 1915 brought the main activities of the Club to a temporary close.

The difficulty of holding central meetings still exists, but it is hoped that that the annual exhibition, the most popular and successful feature of the work of the Club in the past, will be continued with even greater success, and, that in time, when greater facilities arise, the full activities of the Club will be resumed.

PERSONALIA.

LONDON TELEPHONE STAFF.

The following resignations took place on account of marriage:—

Miss H. E. WOOD, Assistant Supervisor, Class II, of Bromley Exchange.
Miss M. A. CURTIS, Assistant Supervisor, Class II, of London Wall Exchange
Miss E. M. FULLER, Assistant Supervisor, Class II, of Museum Exchange.
Miss N. AYRES, Telephonist, of East Exchange.
Miss E. M. BARNES, Telephonist, of East Exchange.
Miss M. E. CLARKE, Telephonist, of East Exchange.
Miss W. BUTCHER, Telephonist, of Hammersmith Exchange.
Miss K. MEAD, Telephonist, of Holborn Exchange.
Miss M. J. BROWN, Telephonist, of Holborn Exchange.
Miss V. COPELIN, Telephonist, of Holborn Exchange.
Miss F. E. JOBSON, Telephonist, of Holborn Exchange.
Miss E. H. HARVEY, Telephonist, of Hornsey Exchange.
Miss E. M. EVANS, Telephonist, of London Wall Exchange.
Miss L. M. MANLEY, Telephonist, of London Wall Exchange.
Miss H. M. WEBB, Telephonist, of London Wall Exchange.
Miss M. AXCELL, Telephonist, of London Wall Exchange.
Miss J. E. BENNETT, Telephonist, of London Wall Exchange.
Miss G. A. DAWSON, Telephonist, of Museum Exchange.
Miss J. Tuddenham, Telephonist, of Paddington Exchange.
Miss M. CROFT, Telephonist, of Paddington Exchange.
Miss N. L. GURNEY, Telephonist, of Park Exchange.
Miss E. M. REYNOLDS, Telephonist, of Park Exchange.
Miss M. M. BLACKBURN, Telephonist, of Dartford Exchange.
Miss B. A. MONK, Telephonist, of Romford Exchange.
Miss SLEAP, Telephonist, of Trunk Exchange.
Miss HOPKINS, Telephonist, of Trunk Exchange.
Miss G. RIXSON, Telephonist, of Trunk Exchange.
Miss W. LAIT, Telephonist, of Trunk Exchange.
Miss E. M. REED, Telephonist, of Trunk Exchange.
Miss I. WILLIAMS, Telephonist, of Trunk Exchange.
Miss MCNAMARA, Telephonist, of Trunk Exchange.
Miss G. A. MARKALL, Telephonist, of Trunk Exchange.
Miss D. G. JENKINS, Telephonist, of Victoria Exchange.
Miss J. A. PARGETER, Telephonist, of Victoria Exchange.
Miss A. BROWN, Telephonist, of Victoria Exchange.
Miss E. PENNEY, Telephonist, of Victoria Exchange.

There were no promotions during July.

SOUTHAMPTON.

At Southampton on July 22, Miss Gibson, Assistant Supervisor Class I, who has been promoted to Supervisor at Sheffield, was presented by the staff, with a beautiful gold wrist watch on a gold bangle. The Postmaster, supported by the District Manager, and Traffic Officers, made the presentation. The Postmaster and District Manager spoke of the efficient manner in which Miss Gibson had carried out the duties of officer in charge of the Exchange and the happy relations which existed between her and both supervising officers and staff of all sections. Members of the staff voiced the feelings of esteem which they had for Miss Gibson. Miss Gibson in acknowledging the gift expressed her great appreciation of the kindness and help she had received from all.

SPEECH THROUGH THE ETHER.

ON Sept. 6, Sir Oliver Lodge lecturing before the British Association at Edinburgh on "Speech through the Ether, or the Scientific Principles underlying Wireless Telephony," said:

Was there anything the ether did not do? Yes, it did not convey sound. Sound was a vibration in matter, not in ether; while light was a tremor in ether, not in matter. They saw through the ether, they did not talk through it. But his subject was "Speech through the ether," speech by means of what they called empty space. How could that be? How could they utilise the ether for conveyance of sound? It could only be done by transmutation. The ether had long been used to convey heat, yet heat was a property of matter. Heat from the sun reached the earth, but it did not travel as heat. At the sun the quiver of the particles was transmitted to the ether, it spread out as radiation, and where that fell it could excite a similar quiver. The heat disappeared in one place, to reappear in another. It travelled continuously as energy, but not as heat. So it was with sound also. The sound vibrations must be transmuted, must be delivered up to the ether to travel as radiation, and at the distant station it must be received by something which could transmute the energy back to sound again.

FAITH IN THE POWER OF DISCOVERY.

The transmutation of heat from matter into etherial energy was effected by the atoms themselves, by mechanism only partially known to us. Through all the geological ages—literally from time immemorial it had been going on. It was not so with sound. No trace of sound reached us from an exploding star. We saw the flash; we heard nothing. To transmute sound into an etherial tremor, and to change it back again into sound at a distant station, required human agency. It needed discovery and invention. Discovery and invention were rife among us, though handicapped in their early stages by poverty and lack of opportunity. Only when some practical result was forthcoming did that difficulty begin to disappear. Faith in the power of discovery, latent in not a few of our strenuous youth, would accelerate the process. Faith removed obstacles, and gave to genius its chance. Other nations would soon be beginning to realise this, if we did not. Great achievements were not due to one man, but to a succession of workers, each passing on the torch to the next. Each man's life was too short for extensive achievement. The great building rose, stone by stone, but it took generations to complete—nay, it was never completed. The long chain of discoverers had no end, and no specifiable beginning. One could but pick out a few salient peaks. Nor was it one line only; it was a branching line. Different paths seemed to converge on some one goal.

It was well to remember great names of recent times. Kelvin, Maxwell, Fitz-Gerald, Hertz, the pioneers on one line; and on another, Crookes, J. J. Thomson, and others who were working hard to-day. The first line dealt with the ether and its properties; the second line discovered the nature of electricity. It was only with scientific principles that he was dealing, not with the technical details of application. Methods of application were protean; many an amateur was acquainted with them, and the subject was advancing so quickly that devices a few years old might hiss the speaker. Each twelve-month teemed a new one. But the fundamental principles remained, and one of these was the nature of electricity.

THE DOCILE ELECTRON.

It had turned out to be corporeal, atomic, or rather electronic. The discovery which closed the nineteenth century was the isolation of the natural unit of electricity. Small almost beyond conception, mobile and active to an extraordinary degree, the electron was becoming our most docile servant. The skill of man had harnessed them; it was by their aid that sound vibrations could be transmitted to the ether, and after transit across great vasts of space could be transmuted back again In an empty Crookes tube they could be driven off from matter. From a hot wire they evaporated, and they could be deflected and guided as we wished. Their obedience was absolute and instantaneous; they had next to no inertia or sluggishness of their own; and they obeyed the slightest force. An electric pole attracted, or else repelled, them, according to its sign; and so their motions could be encouraged or could be checked. If faced with a positive plate, they rushed to it; if the plate was negative, they retired discouraged. Their journey was itself an electric current, and thus they got an electric current varying and responding to every fluctuating control. Electric oscillations were known; we owe them to Kelvin and FitzGerald. They were of extraordinary frequency, millions of vibrations per second, and they generated waves in the ether, as was shown by Maxwell and Hertz. Let them arrange a microphone—an ordinary telephone transmitter to which they could talk in the ordinary way—and let the slow sound vibrations, a few hundred per second, be applied to strengthen or weaken electric oscillations of a few million per second. Thousands of oscillations occurred during the time that every sound wave lasted, and by letting them control a crowd of electrons in an exhausted vessel or vacuum tube their intensity could be controlled by every ripple, every rustle, every shock, and every sibilant which went to constitute human speech. And the radiation emanating from the electric oscillations would then be graduated in intensity, so that the waves which travelled in the ether should be strong or weak exactly as the stimulus required. If they received the electric waves and conveyed them to another empty bulb containing again a hot wire giving off electrons the crowd of particles would respond, another current would be generated, carved into fluctuations of corresponding strength, and these variations of current when employed to actuate a telephone could accurately reproduce the tones of the distant voice.

Digitized by Google

Roughly and generally that was the plan, and by a set of lantern slides he hoped to give some idea of the ingenious devices whereby the astonishing feat was carried out. For it was astonishing. He was not specially astonished by the wireless transmission of coarse signals, like the dot and dash of ordinary telegraphy. It was no more difficult to send impulses across space than to guide them by wires. What Mr. Marconi had made practical as "wireless" might have come in first, and then wires might have been regarded as an improvement, like speaking through a tube instead of shouting into the open air. Any mechanical sending key and many a mechanical relay, could accomplish that. But no mechanical relay could follow the variations of quality in human voice; no agency short of the electron would be quick and docile enough. But with their aid the feat was accomplished, and the electric waves which acted as the intermediary could travel a thousand miles or more before being received and once again transmuted.

VOICES ACROSS THE ATLANTIC.

One more principle he must emphasise. How could the human ear or any instrument follow vibrations of millions a second? It could not. Only the electron could do that. But let them suppose that in addition to the oscillations coming from a distant station they set up home oscillations, in a small subsidiary vacuum tube, of nearly the same frequency. Let the incoming waves vibrate a million times, for instance, while their local arrangement vibrated a million plus 500, what would happen? They would "beat." They would give 500 beats a second, and that was a musical note. To that they could listen, and upon that the variations of intensity could be superposed. This was not the first plan adopted. The first plan was the utilisation of crystals and other detectors, such as the Fleming valve, to rectify the oscillation—to check all the negative pulses and utilse all the positive— to let only one sign through. Thus they got the vacuum valve. But soon this was improved by Lee Forest into a magnifier, so that an original impulse, exceedingly weak, could be strengthened a hundred or even a thousand times by using the electrons as relays, and putting a number of relays in series. So, also, for transmitting, the magnifying device was available. The electric impulses from the first valve, the one directly actuated by the microphone—these need not be given to the ether; they could be used to stimulate another valve, so as to increase their intensity until the waves generated were powerful enough to be allowed to rush across the Atlantic. This they were able to do in a fraction of a second. And there, though what arrived was only a feeble residue, since they had spread far and wide by that time, they still preserved all their peculiarities intact; every pulse of the speech was retained, and could be reproduced, and by adequate magnification could be made easily audible. Distance was no deterrent, it only enfeebled; it did not confuse and spoil, as it did with a wire embedded in the ocean. The properties of the ether were perfect, and all the fluctuations were accurately conveyed. All that they required was a magnifier to get a convenient intensity; and that the ingenuity of man had supplied.—(Abridged from *The Scotsman*.)

THE BAUDOT—XXV.

BY J. J. T.

WE have now reached a stage in the study of the Baudot system where it will be advantageous to deal with the adjustment of the synchronism. By reference to Vol. VI, page 56, Fig. VIII, we recall M, the movable segment connected with the correcting electro-magnet. These are shown diagrammatically, M and CM (Fig. LXIX). The adjustment is known as that of orientation, and consists in placing the movable segment M of the *corrected* station and the segments of Ring I, which, as we know, are connected with the electro-magnet coils one to five of their respective receivers, in such a position as to ensure that they shall each receive the maximum duration of current intended for them. It is indeed *the position of the movable segment which determines* this situation and makes the system not merely synchronous but isochronous.

Upon this movable segment M there is a point to be found where the local current from the tongue of the receiving relay R, which traverses the coils of the electro-magnet correcting coils by the medium of the brush during its passage over M, *is just* sufficient to actuate the armature and its correcting pin. This point is known as the *point of repere.*

Let B (Fig. LXIX) represent Rings 2 and 5 of the distributor of a *correcting* station and A Rings 1 and 4 of its corresponding *corrected* station. Presuming the installations to be of a quadruple 24 segment type then segment 23 of Ring 2 at B will emit the correcting current destined to actuate the coils CM by means of the relay R at station A. Suppose M to be the correct position of the movable segment and that the energising of the correcting coils CM and its armature demand a *duration of the current equal to the time taken for the brush of Ring* 1 *to move from* a *to* a^1 *then* a^1 *is the point of repere*, the correcting currents being received at station A in the positions shown C, C^1.

It will be immediately recognised that the signals transmitted by the Baudot follow one another at equal intervals and are of equal length, be they positive or negative, *i.e.*, 1/13 in a 13-segment, 1/24 in a 24-segment distributor, and so on. Therefore these emissions will be received at similar intervals at the distant end of the line, whatever may be the propagation value of the latter. Suppose now that station B transmits a marking current from segment 19 (or a distance 4/24ths from segment 23) destined to actuate electro-magnet No. 2 and its appendix p^2. This current will *commence* to be received at A exactly 4/24ths prior to the *commencement* of the arrival of the first or marking correcting current, and therefore at p^1. It therefore follows that the *commencement* of *segment* p^2 of Ring 1 at A should be at a distance from the point of repere a^1, equal to 5/24ths, because this point a^1 *corresponds* with the *completion* of the positive correction current, that is the current from segment 23 at B.

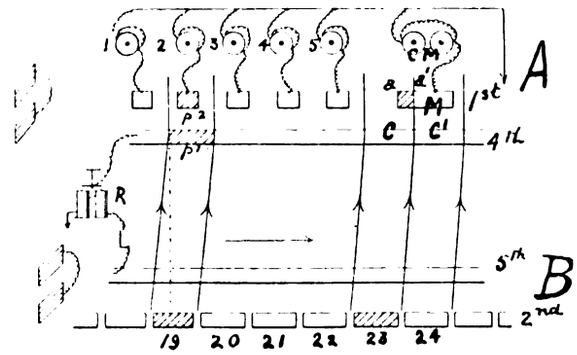

FIG. LXIX.

In this position the reception at A should be exact. Let us now shift the movable segment M to the right, thus extending the distance between M and p^2. This will now be greater than 5/24, and the correction being delayed the current from 19 destined for electro-magnet No. 2 will probably also be delayed sufficiently for some of the current to reach the fourth ring in time to also actuate electro-magnet 3. Indeed if M be moved the distance of a complete segment in the same direction electro-magnet 3 *instead* of 2 will be actuated.

Let us now move M back again into its original position and then in the opposite direction towards p^2. If station B continues to transmit a marking signal from 19 then we shall find that gradually electro-magnet 1 as well as 2 will be actuated until the movement of M continuing in the same direction segment 1 instead of 2 will be actuated.

The practical method of finding the point of repere is by deftly inserting a sheet of paper between the rotating brushes and the movable segment M completely covering the latter. Then with the finger bring the armature of the relay over to marking and gradually uncover M by withdrawing the paper. Watch for the moment when the electro-correcting magnet commences to be actuated. At that moment the edge of the piece of paper will denote the actual *point* of repere and that portion of the movable segment which is then uncovered represents the distance which the distributor brush will have to travel to permit the complete actuation of the correcting system. M should then be moved so that it gives that same amount of surface necessary to coincide with the discovered repere point.

Once fixed the causes which may effect a change in the position of the point of repere are few. The movable contact may itself

Digitized by Google

have shifted through not being tightly screwed in position. A change in the voltage of the local battery of the relay may have taken place. (3) The correcting system may have become less mobile, *i.e.*, the armature may move too stiffly on its bearings or it may have worked down too far away from the cores of the electro-magnet.

In each case it is evident that a longer period of time will be occupied to actuate the mechanism and the point of repere will therefore be a slight distance farther along M in the direction of the rotating brushes. With the present system of secondary batteries the second cause is very infrequent and with careful adjustment and examination of an installation at the beginning of a day's work, stoppages due to these causes should be rare. In cases where owing to changes at repeater offices there may be reason to doubt the absolute accuracy of the repere point it is always possible to make a rapid adjustment by requesting the intermediate office to "give the third," adjustments of M being made by that means. Such adjustments are, however, abnormal and refer generally to foreign circuits.

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

By F. Addey, B.Sc., M.I.E.E., Fellow I.R.E.

(*Continued from page* 185).

Grid Rectification.

The method of detecting signals just described, in which anode rectification is used, is easy to understand, because of the resemblance between its action and that of a simple crystal detector. A better method of using a valve as a detector, however, is that known as "grid rectification." The connexions for this method are shown in Fig. 16, in which the various parts, so far as they are common to both grid and anode rectification, have been lettered to correspond with Fig. 15. It will be seen, however, that in this arrangement the potentiometer is omitted, and that a condenser, C_3, is placed in the lead from the upper plate of the condenser C, to the grid. A high resistance, R_3, is joined between the plate of C_3 which is connected to the grid and the negative end of the filament.

When no signals are being received the grid takes up approximately the same potential as that of the negative end of the filament, because the two are joined together by R_3. The grid potential will not be exactly the same as that of the negative end of the filament. There will be a weak current flowing along R_3 towards the grid, because some of the electrons which are shot off from the filament will be absorbed by the grid. The potential difference between the ends of R_3 so set up is, however, only small, and may be ignored in an elementary explanation of the method. The anode current, therefore, takes the value corresponding to zero grid voltage, as shown by the curve in Fig. 13. (It will be remembered that the grid volts in this curve are measured with reference to the negative end of the filament). At this point the curve is sloping steeply, so that a small change in the potential of the grid will produce a large change in the anode current.

Suppose now that signals from a spark station are received. The train of waves produced by each spark will set the aerial circuit into oscillation, and by means of the coupling between the coils P_1 and S_1 of the oscillation transformer, the circuit C_1S_1 will also be set into oscillation. The potential of the upper plate of the condenser C_1 will therefore alternately rise above and fall below that of the lower plate, which is connected to the negative end of the filament, and these voltage changes will be impressed on the grid through the condenser C_3. The potential of the grid will, therefore, oscillate above and below its steady value, which, as already explained, is that of the negative end of the filament.

We have already explained how, while the filament is glowing, it gives off a stream of negatively charged electrons. It is the stream of these electrons, attracted across the valve to the positively charged anode, which constitutes the anode current. In just the same manner some of the electrons will be attracted to the grid when its potential is above that of the filament, but they will not be attracted to the grid when its potential is lower than that of the filament.

Consequently, as the grid potential oscillates above and below its steady value, the grid, and consequently the plate of the condenser C_3 which is joined to the grid, will pick up electrons during the periods when the grid potential is above that of the filament, while no electrons will be picked up during the period when the grid is negative. Thus during the time that the circuit C_1S_1 is oscillating a gradually increasing negative charge will accumulate on the plate of C_3, which is joined to the grid and consequently the mean potential of this plate, about which the voltage oscillates, will fall. The grid potential will fall in the same way. In the interval between

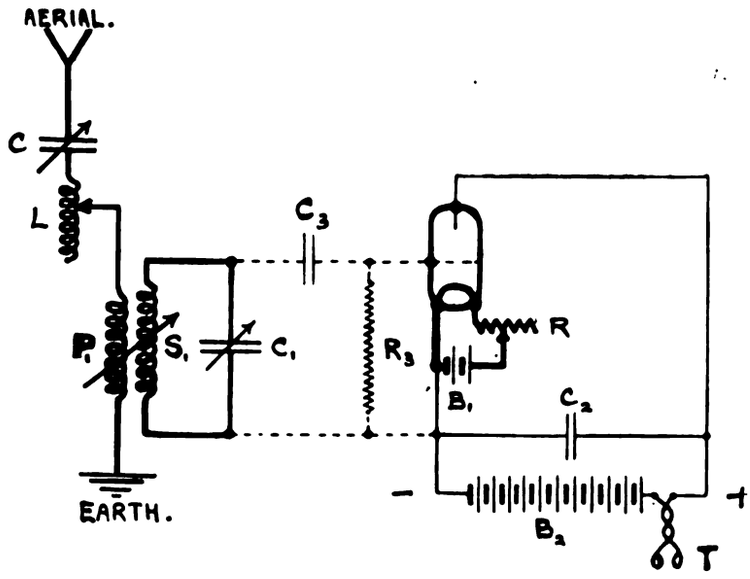

Fig. 16. Grid Rectification.

one spark and the next this accumulated negative charge in C_3 will leak away through the resistance R_3, and the grid will therefore return to its original potential. Consequently, as can be seen from the curve in Fig. 13, the anode current will gradually get weaker during the passage of the train of waves corresponding to each spark, and when the train of waves ends the anode current will regain its original value.

Thus for each spark at the transmitting station the anode current will first fall and then rise again to its original value. Since the anode current flows through the telephones each such change will produce a click, and so, during the time that the key at the transmitting station is held depressed, the musical note corresponding to the rate at which the sparks follow one another will be produced.

Note Magnification.

We have described above how a valve can be used to amplify the high-frequency oscillations set up in the receiving apparatus when a train of electric waves passes the aerial of a receiving station. In exactly the same manner a valve can be used to increase the amplitude of the low-frequency pulses of current which result from the rectifying action of the detector, before these current pulses are sent through the telephones and so rendered evident as sound.

Digitized by Google

It is convenient to have a special name for the amplification of these low-frequency pulses in order to distinguish it from the amplification of high-frequency oscillations. It is accordingly described as "magnification," and the apparatus by which it is accomplished is known as a "note magnifier," since in nearly all modern wireless practice a musical note is heard in the receiving telephones. The connexions of a note magnifier are shown in Fig. 17.

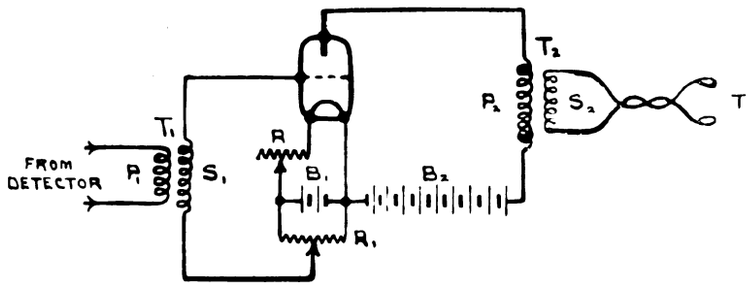

FIG. 17. NOTE MAGNIFICATION.

P_1 is the primary coil of a transformer, T_1, which takes the place occupied by the telephones when magnification is not used. The Secondary coil S_1, of this transformer has one terminal joined to the grid of the valve, and the other terminal joined to the slider of the potentiometer R_1. This potentiometer is joined across the filament heating battery B_1. The brightness of the filament is controlled by the adjustable resistance R.

The high-tension battery B_2 has its negative terminal joined to the filament, and its positive terminal joined to the anode of the valve through the primary coil, P_2, of another transformer, T_2.

The Secondary coil, S_2, of this second transformer is joined to the telephones, T. The potentiometer is adjusted so that the grid is brought to a potential corresponding to about the middle of the straight portion of the characteristic curve, (Fig. 13).

The current pulsations in P_1 cause corresponding voltage fluctuations in S_1. These voltage fluctuations are impressed on the grid and cause the anode current to vary in an exactly similar manner, as already explained. The variations of the anode current in the primary coil, P_2, set up similarly varying currents in the secondary coil, S_2, which pass through the telephones, and so the signals are reproduced. Owing to the steepness of the slope of the characteristic curve small current changes in P_1 will produce considerably larger current changes in P_2, and so the sounds heard in the telephones will be correspondingly louder than if the telephones had been joined up directly to the detector. Without note magnification the energy supplied through the detector is used directly to actuate the telephones, but when note magnification is employed this energy is only used to control the much greater supply of energy from the high tension battery.

(To be continued.)

THE TELEPHONE AND TELEGRAPH SOCIETY OF LONDON.

PROGRAMME 1921-22.

THE meetings will be held at the Institute of Electrical Engineers, Victoria Embankment, and the following papers will be read:—

Date.	*Subject.*
Oct. 17.	"Imperial Telegraph Communications," by Mr. F. J. Brown, C.B.E.
Nov. 21.	"Possibilities of Post Office Development," by Mr. A. C. Winyard.
Dec. 19.	(1) "The Telephone Service: Suggestions for Improvement," by Miss A. Flanagan.
	(2) "The Night Telephone Service and some of its Problems," by Mr. Ernest J. Lansbury.
Jan. 16.	"Printing Telegraphy in America," by Mr. H. H. Harrison.
Feb. 20.	"Women as Civil Servants," by Miss L. M. Herring.
Mar. 20.	"Public Intelligence," by Mr. Bernard Chapman.
April 24.	"High-Frequency Circuits," by Mr. A. B. Hart.

The meetings commence at 5.30 p.m.

THE TRUNK SYSTEM.

BY A. E. COOMBS, LIVERPOOL.

BEFORE me, I have a list of trunk charges issued by the Department in the days of '95. Amongst the centres shown on the schedule are Belfast, Birmingham, Bristol, Cardiff, Exeter, Glasgow, Leeds, Liverpool, Manchester, Newcastle-on-Tyne, Newport, Plymouth and Swansea. The charge for a call from Manchester to Glasgow was 2*s.* 6*d.*, from Liverpool to Newcastle-on-Tyne 1*s.* 6*d.*, from Cardiff to Leeds 2*s.* 6*d.*, and I notice that for calls originated at call offices, graduated fees of 3*d.*, 4*d.*, and 6*d.* were charged according to the distance of the call.

The present day trunk telephonist can have no idea of the troubles of her predecessors. In spite of all, however, the service, such as it was, proved extremely useful commercially, and competition was keen on the part of business men to obtain first use of the trunk lines. Strict priority of connexions had to be observed so that callers interested in similar business should be treated impartially. Even in later years priority of booking as a claim for prior connexion had to be carried out strictly, especially at market opening times. I have known charges of favouritism being made in cases where, owing to some unavoidable cause, a caller was not connected in due turn.

The trunk system developed so rapidly that for some years lines could not be constructed speedily enough to ensure services on a reasonable delay basis. I fear much of this development was at the expense of the sister telegraph service.

About 1904 consideration appears to have been given to the comparative cost of building new lines and of endeavouring to obtain more paid time by improving operating methods. In 1907, Mr. John Lee and Mr. Stuart Jones were appointed Asst. Traffic Managers at Headquarters. I think these gentlemen worked out the details of the arrangement of the call wire and the continuous attention systems of working. Obviously in increasing the number of calls which could be connected in the busy hour by improving the operating methods, heavy capital expenditure required for the provision of long-distance trunk lines could be saved, and development provided for, without great expense. Although operating charges had necessarily to be increased these charges were much less than would be incurred by the cost of erecting and maintaining long aerial lines. Experimental call wire working was therefore introduced between London and Liverpool, and it was found that the average number of effective calls was increased from 10 to 15 per hour. The system provided for subscribers being rung at each end a few seconds in advance of a trunk line becoming disengaged and by this means communication was made immediately a trunk line became available. A disadvantage of the telephone call wire system was that a line had to be withdrawn from commercial use, and this ultimately led to the introduction of telegraph call wires formed by superimposing on a telephone loop. As is often the case the introduction of call wire working gave rise to the problem of dealing with long-distance through traffic, which still continued to be dealt with under the ordinary procedure, for through working. To overcome this the Zone system was introduced This system has been very successful and is not likely to be superseded. A number of the largest trunk centres were selected in accordance with a defined scheme to form Zone centres. Control of all long-distance traffic was vested in these centres and the exchanges associated with them had to circulate the long-distance traffic to the Zone centre. Continuous attention working of Zone lines was introduced about this time. Instead of controlling 4 trunk lines an operator was given 2 or 3 only, and she had to listen-in as far as possible, so that immediately it was apparent that a subscriber had finished conversation, steps could be taken to connect the next call, both waiting subscribers having been rung by pre-arrangement between the exchange operators. At the Zone centre the telephonist was given control of the through calls originated within the Zone for connexion on the long-distance lines, and all traffic was then dealt with in the same manner as calls originated locally.

It might be argued that the holding of short-distance lines for the immediate connexion of long-distance calls lead to delay on the shorter routes, but experience showed that this effect was not so marked as might have been expected. At any rate from an economic point of view line development between the Zone centre and the smaller exchanges could be provided more cheaply and readily, than between long-distance centres. An increase of revenue earning time by 50 per cent. on the long lines was of far greater importance than a decrease of, say 10 per cent. on the shorter lines.

Whilst the Traffic Department improved the operating results the Engineering Department had installed lamp signalling exchanges at a number of Zone centres, and a night concentration system. The time check had been introduced and the calculagraph had been brought into use. The brass connecting test boards had been replaced by the "U" link board which, in turn, gave way to the "Jack" type of board. Cross connecting facilities had been improved and facilitated, and the "morning test" arrangements seemed to have been perfected. Later on, however, the "Megger" replaced the tangent galvanometer. Still, complaints of unsatisfactory conversations were fairly numerous. In spite of the efficient work of the Engineering Department certain trunk routes always gave the testing officers much cause to grumble. In this respect I have retained an appreciation of the work of the testing officers attached to the office at which I made my early efforts

Digitized by Google

to become conversant with the Telephone service. They took a keen interest in their work and I fear the linesmen in the Section had often a rather hard time. These testing officers appeared to know the routes inside out, and in cases of breakdown it was remarkable with what facility they could pick up lines and make "crosses" in order to restore communication. The flexibility of the trunk test board and the standard electrical conditions at all Trunk Exchanges helped considerably in this direction. They had the advantage of having grown up with the development of the system and so had a sound knowledge of traffic requirements and knew on what routes lines could best be spared for the purpose of making good faulty long-distance lines.

In those days the breakdown of even one long-distance line often resulted in heavy delay arising.

As well as being well acquainted with the routes, these officers also knew the linesmen, with the result that co-operation and goodwill was maintained. Of course, it must not be imagined that at all times was there smooth working. I recollect the Wheatstone Bridge test proving the supposed distant looping point to be sometimes incorrect.

The keen interest shown by these pioneers of the telephone test set an example to the men who were to follow them. No line found noisy or of low-speaking efficiency on the speaking test was passed as satisfactory. Every fault noticed was reported to the "Test" officer. These latter were loaned from the Telegraph Branch for operating work in the mornings and evenings and their practical knowledge stood them in good service when they took up testing duties. For reasons of economy, part time operators have been employed during the past few years, yet one is inclined to doubt whether this has proved to be true economy. It is not to be expected that part time men in outside employ will take the same interest in the work as the original staff did. However, this is a digression from the article.

The introduction of the Zone system led to the simplification of traffic circulation and a well-defined scheme was issued in 1906 bearing in view economy in operating expenses and engineering construction. Prior to that time the provision of trunk lines had been made on no properly regulated basis, with the result that through circulation reached a point which was not economical, and much traffic was circulated over unnecessarily long routes. The tendency to centre all trunk lines on the largest towns led to congestion of aerial routes. Direct lines between trunk centres had been provided where justified, and this resulted in the construction of many new routes carrying only a small number of circuits. From a traffic point of view the provision of direct lines was amply justified, but the engineering costs increased considerably. The Zone system had for its object the collection at the Zone centre of all long-distance traffic originated within the Zone area in order to equalise the delay on all calls and to develop the between-Zone lines with a view to Call Wire or Continuous Attention working being introduced and so obtaining the advantages of working on large groups, although in special circumstances direct lines still continued to be provided between towns in adjacent Zones. Systematic traffic statistics were called for. Paid time returns were submitted regularly to Headquarters in respect of all Zone routes worked by call wire or continuous attention, and if the standard was not attained, a satisfactory explanation had to be given. There was usually not much difficulty in furnishing explanations in such cases, as any lapse from the standard was mainly due to interruptions on the lines or difficulty in establishing communication on long-distance through calls.

Returns of the average work done per telephonist during the busy hour were periodically taken and a summary giving a comparative statement of the results at each of the largest Zone centres was regularly issued from Headquarters. By these means a check was kept on operating efficiency and costs. The maintenance efficiency was also kept under review and abnormal loss of the use of trunk lines owing to faults was reported to Headquarters.

Gradually an efficient trunk service was being built up, but the dual control of the telephone system stood in the way of development. Many anomalies existed which could not be avoided. For instance, direct communication might not be possible between two adjacent exchanges because they happened to be in different trunk areas. Then again, the limits of the trunk areas were not based on defined mileage principles. A trunk area in one direction might be on lesser extent in another, and so subscribers connected to one exchange would be able to obtain local and junction communication over a far greater mileage than another connected to an exchange more adjacent to the commercial centre. The dual control necessitated a trunk and a local exchange being situated in many small towns. This was an uneconomical and undesirable arrangement. Housing and operating costs were unavoidably heavy, although it often occurred to me that there seemed to be no insurmountable difficulty in arriving at a system whereby the old Company could have undertaken the trunk work in the small towns. As a number of trunk exchanges were not open throughout the night, elaborate arrangements had to be made to afford a night service by extending the trunk lines at large centres by means of junction lines to the local exchange. When in 1912 the Post Office took over the National Telephone Company's system, the Department had already planned the amalgamation of trunk and local exchanges at many of the small centres; therefore, immediately the transfer had been completed, steps were taken to effect this. Local exchanges were transferred to the trunk exchange or the trunk lines transferred to the local exchange. The saving in operating costs and charges for accommodation must have been considerable, but from a traffic point of view this was not so important a factor as the possibility of abolishing the cumbrous trunk system of communication between exchanges within 30 or 40 miles of each other. With remarkable foresight the Department had already arranged for the laying down of a 200-pair cable between Liverpool and Manchester and in January 1914 a no-delay service was established between these important centres. Subscribers were connected directly by the local exchange operators. The experiment proved entirely successful and has now been extended to other routes.

The working of trunk lines on a no-delay basis between busy centres resulted in a considerable reduction in supervising and equipment expenses. The efficiency of the service was also greatly improved.

Had the war not intervened there seems no doubt that a no-delay service would now have been established on all short-distance routes. Unfortunately many schemes have been retarded and are still held up because of the shortage of material and skilled labour, and in other cases because of the lack of funds. From time to time heavy storms had caused serious breakdowns on the aerial routes, and the consequent dislocation of business led to the Department having to consider seriously the possibility of laying underground cable between the most important long-distance Zone centres. The paper cable had been tested, but the speaking efficiency was not sufficiently good for long-distance work until the loaded and balanced cable came into use. As soon as this type of circuit was proved likely to be successful, funds were allocated for a cable to be laid between London, Birmingham and Liverpool. This cable was, I think, brought into use in 1916. Had the paper cable been a commercial proposition in 1905 it is conceivable that aerial construction would have been greatly curtailed as the advantages of cable lines gained by the absence of faults through storms, saving in ultimate cost, maintenance, expenses and consistency of service are outstanding factors.

In the meantime much had been heard of the tandem and toll systems of working, which were claimed to have been successfully proved out in the United States, and a group of Post Office officers visited the States with the object of enquiring into American standard telephone practice. The outcome of the visit was the introduction of the tandem and toll systems in this country.

A tandem system was introduced at Manchester in the early days of May, 1917, whereby a number of trunk centres were afforded intercommunication on a no-delay basis, and considerable economy in staff and switchboard accommodation resulted. The toll system was installed at London and Birmingham about the same time. It was my misfortune in January, 1915, to be swept up by the wave of patriotism, and I lost touch with telephone progress for over four years. These four years seem now to be part of a nightmare. To live like a rabbit amidst persistent warfare, in an atmosphere frequently reeking with gas and above all to lose repeatedly good and brave friends, left its mark, and I returned to official life ill-equipped to carry on. In the light of after events this absence has been a misfortune in many ways.

With no time for recovery, the service claimed me, in general with others, to strenuous labour in order to restore the service to its pre-war efficiency. During the last two or three years of the war, there appears to have been little progress made with the many schemes in hand for the development of the trunk service. Everything seems to have been subservient to war needs, and the Post Office was faced with enormous arrears of work. Contractors were—and still are— months behind with their work. Shortly after the ending of the war, the public, regardless of the fact that the Department had had a number of its best men serving in the Army, made a great outcry respecting the efficiency and administration of the service, but having in view all the factors it might safely be claimed that the service was maintained in a very satisfactory state of efficiency. If errors in policy have been made, they can with reason be claimed as unavoidable in a service which has not yet become standardised.

Since 1919 the Department in common with commercial businesses has had many difficulties to overcome, and in spite of the loyalty of its officials it is only recently that results are being obtained commensurate with the labour entailed in bringing the service to the old standard. Cable schemes for the improvement of the trunk service are gradually being completed. The time should not be far distant when service on a no-delay basis will be afforded between all exchanges within 30 or 40 miles of each other and long-distance calls connected consistently within 20 to 30 minutes. As a traffic officer I hope that the ideal of a no-delay service between all long-distance centres with close commercial interests will eventually be attained.

Looking forward there appears to be no reason why the development of the trunk service should not be equal to that before the war. Gradually the working of short-distance lines will, I hope, be placed on a no-delay basis and worked similarly to the old junction services. Operating costs will be reduced, long-distance lines will, I suggest, be worked by the Continuous Attention method which, although increasing the operating expenses, will result in full use being made of expensive lines and so save the heavy charges of laying high-grade cables. To the Engineering Department we must look for line efficiency and to the grading of lines in order that construction expenses may be reduced to a minimum. A definite and consistent policy is now all that is needed to make our trunk service unequalled for efficiency in the world.

The foregoing does, I think, prove that the Department has justified its control of the trunk service, and that it is not asleep. One hears of the remarkable efficiency of the American long-distance service, but I imagine this can only be the case on services which are specially maintained by the Bell Company. For consistency of service it would be interesting to learn how the general efficiency compares with that in this Country. At any rate I have heard Americans temporarily resident here speak highly of our long-distance service.

REVIEWS.

"Automatic Telephone Systems." By William Aitken, M.I.E.E., A.Am.I.E.E. Vol. I. Messrs. Benn Brothers, Ltd., 8, Bouverie Street, London, W.C.4. 25s. nett.

The author of this volume whose name is familiar to Telephone men throughout the world as being the father of *Aitken's Manual of the Telephone*, has made what, so far as we are aware, is the first attempt to deal with the whole subject of Automatic Telephony in one book, the second volume of which is not, however, yet ready for publication. The advantages of such a book are obvious. One book serves the purpose of several and it is not necessary to consider the need for discounting the treatment on a particular system as is so necessary where the author of a book deals with one system only, and is therefore prone even if not an interested party, to laud that system over all others. In Vol. I Mr. Aitken deals with the Strowger System, and the systems of Messrs. Siemens Brothers & Co., the Western Electric Co., the Relay Automatic Telephone Co., and the Coventry Automatic Telephones, Ltd., so far as the exchange equipment is concerned; and in Vol. II (still in the Press) it is proposed to deal with equipment in subscribers' offices, including party line and switchboard working and satellite offices, trunk and toll line working, lay-out of plant, traffic problems, power plant, &c.

The first volume is arranged in 83 sections, any one of which it is apparently the intention of the author to rewrite when it becomes out of date; and the 83rd section contains the present standard terms and definitions. The size of the pages is larger than is usual, and advantage is taken of this fact to make the diagrams clearer and more easy of reference. The diagrams are indeed an outstanding feature and the adoption of numbers for the circuit routes, on the analogy of the treatment of "bus routes" on the familiar transport maps of London, does much to avoid the confusion which seems inseparable from circuit plans of automatic telephone systems. Indeed, it is possible to read the diagrams without going over the lines laboriously with a pointer and incidentally straining one's eyesight in the process.

We shall welcome the second volume.

"Thermionic Tubes in Radio Telegraphy and Telephony. By John Scott-Taggart. Published by The Wireless Press, Ltd., 12 & 13, Henrietta Street, Strand, W.C.2. xxiii + 424 pages. Price 25s.

Although many books on thermionic tubes have recently been published, the one under review fills a place which is occupied by none of the others.

In these the matter has been dealt with mathematically, and although in general they are admirable expositions of the subject, yet the reader without the necessary standard of mathematical knowledge finds himself unable to take full advantage of them. The present book deals with the subject in a non-mathematical manner, and the average operator and amateur who wishes to know the "reason why" of the apparatus which they manipulate will find it exactly the kind of treatise which they require.

The first chapter deals with the general theory of thermionic currents and their use in two electrode valves. In the second chapter the effect of the introduction of the grid is discussed. Then follow chapters on the principle of retro-action, on multi-stage high and low frequency amplifiers, on combined high and low frequency amplifiers, and on various arrangements in which the principle of retro-action is applied to multi-stage amplifiers.

The detection and generation of continuous waves are next dealt with, followed by a description of the use of the valve in the various measurements required in wireless telegraph practice, and of its application for wireless telephony.

The two last chapters deal with the dynatron, the trigger relay, and several other miscellaneous devices in which use is made of the valve.

The get-up of the book is very good, the diagrams are excellent, and the number of printer's errors, usually large in a first edition, is extremely small.

There are only a few points which we have to criticise unfavourably.

On page 4 the author states that if a body possesses more detachable electrons than another, the first body is said to be at a higher negative potential than the second. It may be "said to be," but whether it is or not will of course depend on the relative capacities of the two bodies as well as on the magnitude of the free negative charge on each.

On page 97 the "characteristic surface" of a valve is mentioned, without any explanation having been given of what the characteristic surface is.

In the explanation on page 157 of the simple retro-active circuit shown in Fig. 118 reference is made to a certain coil "R" which does not appear in the diagram. From the context it would appear that it is the coil AB that is meant.

There is one other point which we must apologise for mentioning, but which we feel seriously detracts from what is otherwise a most excellent book. It is quite possible that in the natural enthusiasm inseparable from the production of a book of this description the writer has overlooked the danger of presenting to the public eye those more intimate moods which, especially as time softens one's youthful elations, are generally reserved for moments of private introspection. A glow of satisfaction following on efficient achievement is undoubtedly one of the legitimate rewards of the worker in any sphere.

Such paragraphs convey no information to the reader, but only tend to make him form a prejudiced opinion not in favour of the book as a whole. As we have indicated above, we consider that anyone who formed such an opinion would be wrong, but we can appreciate their feelings in the matter.

We have no doubt that the author's expectations as to the need for a second edition will be justified, and we would strongly recommend him in that edition to make the modifications we have suggested. We feel sure that he would not lose by the change.

ADVICE TO DIRIGEURS.

BY O. N. THESURFACE.

"Your committee visited Manlivgow, where they observed a number of the staff standing idle. They were informed that these were dirigeurs." Extract from a peregrination report:—

When the visitors come round,
Look Busy!
If the Traffic Staff abound,
Look Busy!
You can "cod" the bloomin' lot,
If you're cute upon the spot;
Run your apparatus hot!
Look Busy!

When Committees you espy,
Look Busy!
When economists ask Why?
Look Busy!
With a relay or a trad,
"Use the wit you've got," my lad,
They're appointed to be "had."
Look Busy!

You know the "C & S" creed—
Look Busy!
All your bonus you will need,
Look Busy!
On the Western or Baudot,
You can reap whate'er you sow;
And you'll earn your watch below.
Look Busy!

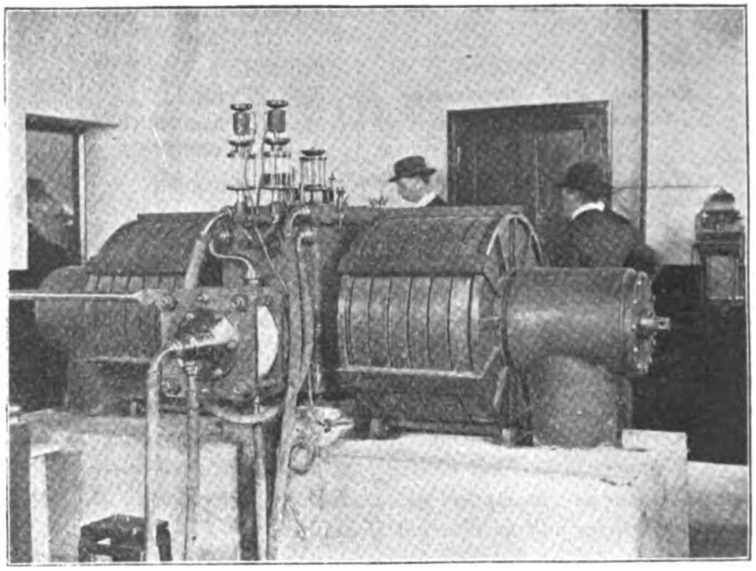
OPENING OF LEAFIELD WIRELESS STATION.

THE high-power wireless station at Leafield (Oxford), which forms the first link in the projected wireless chain which is to link up the scattered portions of the British Empire, was opened by the Postmaster-General on Aug. 18.

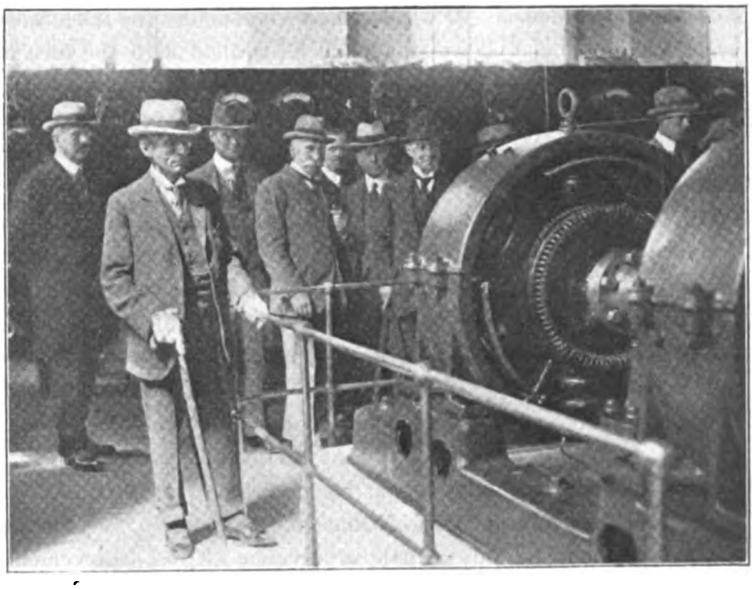
The station is situated on the Cotswolds, about twenty miles north-west of Oxford. It is equipped with two 250-kilowatt Elwell-Poulsen arcs of similar design to those fitted at the large French stations at Lyons and Bordeaux.

It will exchange traffic with a similar station which is being erected at Abu Zabal, near Cairo. It is hoped that this station will be ready in about three months time. The chain will be continued *via* a station in East Africa to South Africa, and *via* India and Singapore to Hong Kong and Australia.



GENERAL VIEW OF WIRELESS STATION AND COOLING POND
THE MASTS ARE 300 FEET HIGH.

The charge for messages between England and Egypt by the wireless route will be 9*d*. per word, as compared with the cable charge of 1*s*.



On the occasion of the opening ceremony two messages of greeting were sent out by the Postmaster-General, first to British stations and then to foreign stations. Replies by wireless were received within a few minutes from Malta, Paris, Rome, Budapest, Posen, Norway, Sweden and Germany, signals being reported as good and clear. Later replies were received by cable from more distant stations where the wireless transmitting apparatus were not sufficiently powerful for signals to be received in this country, and it is interesting to note that the messages from Leafield were read clearly at places as far afield as Constantinople, Mosul, Bermuda, and Barrington (Canada).

When the service between England and Egypt is in operation, the transmitting apparatus at Leafield will be actuated over a land line from Banbury, where the receiving apparatus will be situated. This arrangement will enable the system to be worked duplex, the receiving apparatus at Banbury being arranged so as to be unaffected by the signals radiated from Leafield, but at the same time to respond to signals from Egypt.

The provision of this new line of communication between England and the near East will not only be of great importance from the strategical point of view, but will afford a much needed relief to the submarine cable system.

The Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.1. The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VIII. OCTOBER, 1921. No. 79.

WIRELESS AND ITS PROPHETS.

WIRELESS has caught the imagination of the public. We need not resent the fact. As Sir Oliver Lodge says it is just the mischance of sequence. If wireless had come before the telegraphy which we know so well we should all be thrilled with the idea of confining the impulses to a wire and multiplex would arouse the journalists. There are no bounds to the achievements of wireless in the minds of an old friend "the average reader." He can tell us of gunboats which leave Portsmouth without a soul on board steered safely by wireless waves and having guns which can be directed and shot by the same mysterious energy. The tribute which he pays to the unseen is also a tribute to the incomprehensible. He awakes each morning to a new discovery. The fell influence of atmospherics is no more ; it is gone with the King's Evil. The problem of overhearing is solved again and again. Through the mysteries of a wealth of technical language he threads his way, and he is as convinced that there is no world left for a Columbus or an Alexander as was his predecessor in the Victorian Age. It would be a pity to disillusion him, and in fact for all we know he may be only a little in advance of real achievement. Who shall set a bound to achievement ?

For all that it is just as well to understand that there remain some difficulties to be surmounted. Atmospherics have not yet entered the swine of Gadara in despair at having anything else to upset. The truly faithful wireless expert is modest and humble. He emphasises what has not been achieved rather than what has been achieved. He is anxious lest there should be premature optimism. Of course that makes a poor appeal to popular psychology. Modesty and humility always do. The positive assertion is "the stuff to give 'em," but sooner or later they may ask for more nutritious food. The man who says sweepingly that in six months' time there will not be a telephone exchange, but that everyone will have a machine in his pocket with which he can speak at will to the Shah of Persia, will make a sensation which may not outlast the six months. The true scientist, however, will go pegging away, facing difficulties, accomplishing a little achievement to-day and another to-morrow, and conscious all the time that the future of telegraphy may lie neither with the wire as we have understood it nor with the wireless as we have not succeeded in understanding it. The newspapers will not find in him a daily thrill, but he will be the true benefactor in the end.

After all, the need is for the hour by hour transmission of written or spoken messages. To achieve this is worth all the research and experiment. There are routes where, obviously, wireless transmission will have advantages. At the risk of seeming to be dull reactionaries we may hazard the opinion that there are routes where a wire, worked by modern economic methods, will have greater advantages. Capturing the public imagination is a fine art, but the public imagination may grow weary of exercise. It may ask to pass from faith to sight. It may grow impatient of the process, if unduly prolonged, of passing from faith to sight. Wonderful things are being done by wireless, but they are not quite so wonderful as the promise. And it may not be amiss to say that the soundest empiricism is to be found in the actual working of routes, short routes and long routes, with living traffic. That is going on, so to speak, under our noses. It is not so theatrical perhaps and it leaves the heavily-leaded "caption"—if that is the word -but a poor chance for display. But it goes steadily on.

THE TOLL EXCHANGE.

THE completion of the new Toll Exchange which was formally opened by the Postmaster-General, Mr. Kellaway, on the 17th inst. marks an important step forward in British telephone practice. Henceforward it will be possible to obtain immediate trunk communication, without going through the trunk exchange, with all telephone subscribers within 25 miles of London. The saving in time may be gauged by the fact that generally speaking three telephonists will handle the call instead of seven and that 350 direct short distance lines are connected with the new exchange. It is true that trunk service on a no-delay basis already exists between Edinburgh and Glasgow, Manchester and Liverpool, and between the large towns in South Lancashire, the West Riding and the Black Country. There is, however, no great centre of population within short distance of London comparable with those separated by 20 or 30 odd miles in the districts mentioned ; indeed, save Brighton and Southend there is no town of 100,000 inhabitants within 50 or 60 miles of the metropolis. But, within a radius of 25 miles there is a populous area studded with important medium-sized towns, both of a residential and business character, such as St. Albans, Luton, Watford, Maidenhead, Windsor, Dorking,

Digitized by Google

Sevenoaks, and Gravesend. To these a no-delay service is now obtainable, and it is proposed in the near future to extend the radius to 50 miles, thus including Brighton, Reading, Southend, Bedford, Chatham, and other important places. When it is understood that about 35 per cent. of the trunk traffic consists of short distance calls, it will be realised how considerable a relief has been afforded to the trunk exchange by their deviation to the Toll exchange.

Mr. Kellaway inaugurated the first call from the Toll Exchange, obtaining communication with Col. Grant Morden at Uxbridge, in a fraction over 10 seconds. In an allocution to those present at the opening ceremony he expressed the hope that this would prove a happy augury for the success of the new exchange.

HIC ET UBIQUE.

THE publication of the Preliminary Census Returns affords an opportunity of estimating afresh the population of the London Telephone area. The old boundaries of the area of course disappeared with the introduction of the new rates in April last, and the present area is that included within a ten-mile radius from Oxford Circus, embracing Enfield, Ilford, Woolwich, Bromley, Croydon, Kingston, Harrow and Edgware. The population of this area is as nearly as can be gauged 7,068,500. The old larger area contained in 1911, 7,160,000 people. There were 331,910 telephones within the ten-mile radius at the end of April last, or one to every 21.3 inhabitants.

THE storm of the night of Sept. 11-12 caused considerable damage to the telephone system in the South of England. The breakdowns were chiefly caused by trunks and branches of trees falling across the lines; 200 subscribers' lines were broken down in Brighton, of which 70 were restored on the 12th and the bulk of the remainder on the following day. The main route to the Continent was brought down by a falling tree between Canterbury and Faversham, 12 poles were affected, and two Paris, two Brussels and the Lille circuit disturbed. They were restored on the following day, and indeed all the trunk and local wires affected on the South-East were dealt with very expeditiously.

ACCORDING to the *Morning Post*, Russia is another of the countries in which incredibly enormous charges are made for telephone and telegraph service. We learn that a single subscriber pays 350,000 roubles a year, a "collective" installation (one in a large house used by several people) 500,000 roubles a year. Trunk calls (for distance not stated) 7,200 roubles for 3 minutes. Local telegrams cost 100 roubles a word, long-distance telegrams 500 roubles, and urgent telegrams 3,000 roubles a word.

A TELEPHONE call office has been opened at Radford Semele in Warwickshire. This is not the only small parish with a quaint and intriguing name which the telephone reaches. Ampney Crucis, Zeal Monachorum, Steeple Bumpstead, Kingston Bagpuze, Lytchett Matravers, Middle Wallop, Upper Slaughter and many others are thus favoured; but Ryme Intrinseca, Toller Porcorum, Whitchurch Canonicorum, Kingsbury Episcopi, Collingbourne Ducis, Broadwood Widger, Berrick Salome, Flyford Flavell, Ewyas Harold, Messing, Mucking, and Great and Little Snoring are still amongst those engagingly named villages which are never in a telephonic sense "engaged."

BOOTH-BAUDOT DUPLEX.

THE Postmaster-General has awarded £100 to Lieut.-Col. A. C. Booth, M.I.E.E., as a gratuity in recognition of his invention and services in connexion with improvements in Telegraph working. This applies more particularly to the development of the Booth-Baudot Duplex giving 6, 8, 10, and 12 channels per circuit in place of the 3, 4, 5, or 6 channels by the ordinary Baudot as used in France for some 40 years.

In addition to the extensive inland service embracing both Scotland and Ireland, the system has spread to the Continent, being used on cable circuits from this country to France, Belgium, Holland and Germany, as well as between Marseilles and Algiers. Our Dominions also are about to use it, or some of its developments.

The first publication of the "Booth-Baudot Duplex" was made in Col. Booth's paper read before the Institute of Post Office Electrical Engineers as far back as March 1907. The world-wide demand for copies of this paper very quickly exhausted the supply, but the subject matter and most of the illustrations and diagrams have been reproduced by permission of the I.P.O.E.E. in modern books on Telegraphy.

The Postmaster-General's minute states that the installations of this apparatus resulted in the release of many Morse Telegraphists for the Signal Service of the Army. The Booth-Baudot Duplex has therefore contributed its share to the successful issue of the war.

The system was first started in June 1910, and its growth in the comparatively short space of 10 years has been extraordinary. The resulting economy in carrying on the world's telegraph service must be considerable.

TELEPHONE SERVICE.

FROM THE SUBSCRIBER'S POINT OF VIEW.

THE writer of a recent article in the JOURNAL put forward a plea to the effect that the subscriber's point of view should be considered more frequently than it appears to be at present. This is salutary, as it is feared that the telephone officer is apt to fall into the snare of viewing the question of service from an operating and engineering point of view unduly, and is sometimes too prone to make excuses, or perhaps it should be said to give reasons, why the subscriber should not receive the service for which he pays. It is thought, therefore, that a short dissertation on the subscriber's view of a telephone service may not be amiss, especially in these days when a considerable amount of adverse criticism is levelled against the service. There is some difficulty in treating such a subject in an interesting manner owing to the fact that there is very little new which can be said. This ground has been well ploughed and harrowed in the past. It is only by ploughing the same old earth each year, however, that the harvest for our daily bread is reaped, and in telephone matters old standing axioms have to be reiterated in order that a reaping of good service may ensue.

In viewing telephone service from the subscriber's standpoint, there are four outstanding points that appear to be uppermost in the minds of the public, and these are:—

Prompt answer from the exchange.
Quick and accurate connexion.
Freedom from faults.
Moderate cost.

There are other points such as courtesy and good transmission which may be sometimes at the back of his mind, but from a varied experience of the subscriber's requirements as he can voice them, it is thought that the four points enumerated sum up the essentials. Courtesy is taken for granted as the debt due between one individual and another, and such points as good transmission are left to the telephone officials as being of a more technical nature and demanding expert knowledge. The four headings, however, are simple, and the general public can readily voice a very definite opinion on them. It is proposed, therefore, to take them seriatim.

Digitized by Google

Prompt Answer.—Fundamentally, the telephone stands as a quick means of communication of oral messages between two people, and delay at any point in establishing a telephonic connexion detracts from its usefulness. It is therefore of great importance to a subscriber to have his calling signal answered by the exchange in a prompt and business-like manner. To be greeted quickly and cheerfully gives him a certain amount of confidence in the service and, as first impressions are lasting, he remembers a slow answer even if the further process of establishing the call is performed in good average time. Delay in the first stage of a call is apt to upset the subscriber's balance for the remaining stages and any trouble afterwards is magnified until he feels that he is a much abused individual. Slow answer gives rise to many hallucinations in the subscriber's mind, such as tea-drinking, reading and talking on the part of the operators, and that they will do anything rather than attend to the subscriber's signals. All this is very amusing to those who are actually employed in the telephone business, but if the subscriber's point of view is still pursued it may be seen that there is some excuse for his views whether they are correct or not. Telephone operating to the subscriber at the telephone, is invisible, and the process may be classed as doing business by proxy. When you do business in a shop you see what is going on, and if there is delay in serving you, there is generally a certain amount of interesting material to occupy your attention and prevent you working up a formidable grievance. You can also see that you are served in your turn or perchance you may find some interest in trying to get your order placed before other customers with a longer term of waiting have caught the assistant's eye. The invisibility of the operating to the subscriber explains to a large extent the remarkable phenomenon of the rapid passing or accumulation of time in the caller's mind when he is waiting at the telephone. If he waits 10 seconds, it is magnified at least three times, and it is rarely that a subscriber will condescend to mention seconds when complaining, it is generally minutes he deals in. The subscriber lifts his receiver, stares at a blank wall, tatooes with his fingers on the table or indulges in other performances not calculated to soothe the nerves. It might be worth while considering the question of supplying the subscriber with a little jazz music over the telephone from the future exchange band while he is waiting. To put joking aside, however, the fact that the subscriber does not see what is taking place during the establishment of a call makes his position somewhat difficult and the situation calls for a great amount of courtesy and tact on the part of the operators.

It is necessary, however, to protect the subscriber from himself; for although he desires an immediate answer to his signal every time he calls, such a state of perfection would make a very costly service, and it is well known how the question of price affects the telephone public. The erratic incidence of traffic and the longer time taken to establish difficult calls have to be taken into account in arriving at a reasonable average time of answer which will be satisfactory to the subscriber and the department. At the same time it is well to bear in mind that the subscriber lays considerable stress on a prompt answer from the exchange and that a quick and business-like salutation gives him a certain degree of confidence in the service.

To provide as even and rapid a time of answer as possible, there are two essentials necessary in the exchange and these are team-work and answering calls in sequence. These points have been so well drilled into the operators that it is inviting trouble to offer any explanations at this time of day. This much may be said, however, that the careful practice of the virtues of team-work and answering in sequence makes all the difference between an even and satisfactory time of answer and an erratic service with long delays in answering.

Quick and Accurate Connexion.—It may be taken that the subscriber is not particularly interested either in the methods of establishing a telephone call or of the difficulties to be overcome before he gets in conversation with his client. If he is of a scientific or enquiring turn of mind, he may evince some interest in the procedure during his quieter moments, but when he makes a telephone call, all he desires is to get in touch with his client as quickly as possible. This is quite a natural state of mind and is borne out in our daily life in all directions. For instance, when the electric light is switched on who desires at that moment to know the process of manufacture or the difficulties of supply to be overcome? All that is desired is the luminant and if it fails—well, most of us are in as bad a way as the average subscriber is when something goes wrong with his telephone call. There is, therefore, no doubt that to a subscriber requiring a quick connexion, a wrong number, cut-off, or a false "no reply" is very provoking, and it can be understood that when such a thing happens, many subscribers are not in a fit state of mind to accept an explanation. It is strange that, according to the subscriber, trouble generally takes place on important calls. If viewed, however, from the subscriber's standpoint all his calls are important, and therefore it is easy to understand the extraordinary failure of the important connexions. The principal difficulties experienced by a subscriber are as already stated "wrong numbers" "cuts-off" and false "no replies." These troubles are easily accounted for by those in the service but to the outside public they are heinous offences and are the cause of much complaint.

It cannot be expected, however, that all calls will go through sweetly, but it is up to the telephone officers to see that there is a minimum of difficulty and if a call does go astray, the subscriber should be tactfully dealt with and not spoken to as though he caused the difficulty himself. To keep difficulties at a minimum the following broad axioms are put forward with apologies for their antiquity and reiteration:—

> Clear enunciation; give subscriber time to make necessary corrections; careful connecting and disconnecting; changing junctions, and if possible, subscribers' lines before giving "no reply."

Freedom from Faults.—This is another point where the subscriber is not interested in the difficulties attendant on his telephone service. If his telephone is out of order, it matters little to him whether it is caused by an earth on the "B" line, disconnexion at the D.P., or any of the other technically known points of trouble. His telephone is out of order and that is sufficient for him. He states that he is paying for a service and that the knowledge of the number of soldered connexions or intricate apparatus is no compensation if he is not receiving what he pays for. It should always be borne in mind that the subscriber supplies the sinews of the service and as such, he is the one who should receive the necessary attention. It is, therefore, of the greatest importance that faults should be cleared quickly and with as much permanence as possible. The telephone is of vital importance in cases of emergency and as great a degree of reliability as possible should be the aim of the Department in order that loss of life or property may not be attributed to a faulty telephone line or apparatus.

Moderate Price.—The subscriber desires as cheap a telephone service as possible, but at the same time he wishes it to be speedy and reliable and not a gimcrack affair. It is beginning to be recognised to a certain extent that a good telephone service implies a heavy money outlay, and unless a deficit has to be borne by the State it is difficult to run a service as cheaply as the public would like. The subscriber claims that the telephone is a business necessity, and that if it is expensive, there is a danger of business being hampered. At the same time, if the subscriber is reasonable, he will admit that a good service is a valuable asset and as such its value is worthy of an adequate monetary return. The matter of telephone costs, however, is an academic one, and the issues have to be so well thought out from every point of view that it is beyond the scope of an article such as this. Still there is no denying the fact that the public wish as cheap a telephone service as possible consistent with a reasonable efficiency.

TELEGRAPHIC MEMORABILIA.

SOME time ago the Admiralty announced that an International Hydrographic Bureau had been established at Monaco, Vice-Admiral Sir John Barry and Captain Spicer-Simson representing Great Britain together with Captain Phaff and Captain Muller from the Netherlands and Norway respectively, forming its directors. The Bureau is the result of a London conference held in 1919 at which 20 States were represented, 19 of which approved the statutes then drawn up, and constituting themselves members of the same. The Argentine Republic, Belgium, Brazil, the United Kingdom and Australia, Chili, China, Denmark, France, Greece, Japan, Monaco (the Prince of Monaco is particularly interested in oceanography), Netherlands, Norway, Peru, Portugal, Siam, Spain, Sweden and Uruguay. This institution should prove of inestimable value to telegraph engineers engaged in the laying of submarine telegraph and telephone cables, for which there is likely to be ample demand for many years to come despite, or perhaps because of, the extremely interesting developments of wireless systems as applied to both telegraphy and telephony.

These developments as foreshadowed are proceeding very largely along the lines of improvements in selectivity and the elimination of atmospheric disturbanes together with increases in speed. The chairman of the Marconi Company (Senor Marconi) at the Twenty-fourth Ordinary General Meeting of the Company claimed that the successful solution of *elimination* had been very nearly reached and even foreshadowed the possibility of wireless telephony between this country and Australia. In the opinion of this expert, however, wireless telegraphy must exist before there is a possibility of the other. Chatting with other experts the writer has had the privilege of obtaining other views which if one may write the words, have arrived at a less optimistic forecast to the extent that they counselled considerable further expenditure on submarine cable construction in the near future. Again, on the other hand, one hears the youthful scientific seer visualise the time when selectivity shall have reached that fineness of adjustment where the mesh of the sieve shall prove so minute and accurate as to make it easily possible to distinguish between waves of a difference of but one metre! With this range of studied opinions from which to choose one can only wait and watch with open mind the gradual and wonderful evolution.

By the way, the Spanish courts have given a verdict in favour of the *Compania Nacional de Telegrafia Sin*, Hilos, and the Marconi Company against the *Compania Iberica de Telecommunicacion* for infringement of certain patents relating to thermionic valves.

Reverting to the science of hydrography, a correspondent writes the following interesting paragraph: "Deep sea soundings taken by the British and American gun-boats *Challenger* and *Dolphin* in the Atlantic are full of interest to telegraphists. These soundings show an immense ridge running roughly North and South in mid-Atlantic, rising almost sheer about 9,000 feet from the ocean depths around it, the higher parts being only a hundred to a few hundred fathoms beneath the surface." Think what a splendid chain of telegraph repeater stations could have been erected on these mountain peaks had they not disappeared in the gigantic cataclysm of some ten thousand years B.C.! That at least is the approximate date given for the disappearance of the legendary ancient continent of Atlantis, of which the Azores may be presumed to have been a part. By how many multiples of an aeon this may have to be magnified let the modern geologist determine when the mystery attached to the source of our sun's energy has been solved! The present situation in mid-Atlantic is that owing to the dearth of landing places the Azores stands a very good chance of one day becoming a submarine telegraph Atlantic centre, and a veritable International submarine cable Clapham Junction. The following information culled from the *Electrical Review* would appear to be specially *apropos* of the subject:—

> "In the event of the reported allotment of one of the German cables between South America and the Azores to Italy being realised, the Italian Government intends to lay a complementary section between the Azores and Italy, and thus establish for the first time direct cable connexion between Italy and the American continent. The cost of the complementary section has already been reckoned and is set at 20,000,000 gold lire. The scheme will have a further complement in that it will eventually enable direct connexion to be made with Northern Europe. The saving upon the fees now paid to foreign cable companies for the carriage of messages will suffice to pay for the outlay on these several schemes, estimated to cost over 75,000,000 gold lire."

From the same reliable source it is also gathered—

> "that a Bill authorising a concession to lay a cable between Italy, Spain, Brazil, Uruguay, and the Argentine was introduced at Rome on July 23."

These last two items are a very clear indication of the activities in the realm of wire telegraphy as are the following paragraphs in that of *Wireless*. The Perth (Western Australia) Observatory authorities are installing a wireless telegraphic receiving apparatus which will be capable of intercepting messages over a distance of 12,500 miles.

> "The wireless station at Bamako in the French Soudan, begun in 1918, is expected to be finished before the end of the present year. During its construction a temporary post of 10-k.w. capacity with musical spark was set up to maintain communication between Bamako and the coast stations. When completed the Bamako station will be the chief one in the French Soudan, and will have antennæ with horizontal emission, supported by six 120-metre high towers. The other equipment will comprise two 275-h.p. Diesel engines to yield the motive power. Transmission will be made by quenched wave with a 100-k.w. alternator group. Later on a second group will be installed."
>
> "The Polish Government appears to have made a contract with the Radio Corporation of America for the construction of a $3,000,000 high-power radio station at Warsaw, having direct communication with Rocky Point, Long Island. It is understood that the Polish Government will own the station, which will be operated in conjunction with the Radio Corporation for a period of 30 years."
>
> "On the authority of the Stockholm *Svenska Dagbladet* it is stated that the negotiations for the amalgamation of the English Marconi Co. and the Swedish Radio Co. have led to positive results, but the majority of the shares will remain in Sweden."

The White Star steamship, *Majestic*, the largest vessel in the world, is fitted with three wireless stations, the largest being capable of maintaining permanent connexion with both Europe and America during the whole of a trans-Atlantic voyage. Elaborate submarine signalling gear has also been provided so as to ensure as far as humanly possible the safe navigation of the vessel in fog. Two of the motor life-boats with which she is provided are also equipped with wireless installations.

The petition of the Institution of Electrical Engineers for a Royal Charter of Incorporation has been approved and a Royal Charter granted. His Majesty the King has expressed his willingness to become patron of the institution.

According to Reuter's Trade Service of Stockholm, the Swedish Telegraph Board's annual report for 1920 shows an increase in revenue of Kr.20,000,000, making a total of Kr.90,000,000. This increase is due to the raised fees, but expenses are also higher. The net profit works out at Kr.10,000,000.

It is understood that the Russian Soviet Government has granted a concession for telegraphic connexion between Russia, Denmark, Japan, and China to a Scandinavian company.

Items of information which come to hand from time to time from one source and another regarding telephonic conditions, and results should on the whole tend towards satisfaction with State management in this country. Was it not Hull which was held up as an example of the best served town in the Kingdom? It has fallen on evil days with a deficit of £13,279 on a year's working. Turn we now to Czecho-Slovakia, where by a new law, according to the *Exchange Telegraph*, all telephone subscribers to the State service must buy a minimum of 6,000 kronen in Government bonds. Anyone refusing to make the purchase will have his or her telephone cut off. Two hundred kronen is equal to about £1 at the present rate of exchange. Needless to say, protest meetings have been held!

On Aug. 8 of this year there passed away in his 90th year at Winchester, one of the early pioneers of industrial electricity as represented by the electric telegraph and electric lighting. Samuel Alfred Varley, A.M.I.C.E., as a boy attended Faraday's lectures at the Royal Institution, and was the son of Cornelius Varley, artist and microscopist. He was associated with one of his brothers, Cromwell Fleetwood Varley, in the laying of at least one of the Atlantic cables. He went out to the Crimea during hostilities as electrician and was probably the first to instal and operate a field line telegraph in actual warfare.

According to an informant of *The Times* newspaper, East of the Volga the peasants attribute this year's drought to the wireless apparatus erected on the Votkin works. "They stuck an iron pole into the sky and that stopped the rain," they say. One wonders if this is more ridiculous than the attempt of certain enterprising (?) and intelligent leaders of public opinion who here in the capital of our educated empire discharged tiny fire balloons in order to bring the rain down!

A telegraph engineer specially expert in high speed type-printing telegraphy writes a very interest letter on Tape and Page printing anent certain observations which appeared in these columns some time since. His opinion and experience are willingly placed before the readers of the T. AND T. JOURNAL. He says:—

> "There is of course much to be said for both Tape and Page printing. Tape printing is good for very long lines when a greater speed than 30 to 35 words per minute cannot be obtained. At this speed it is possible for operators to gum the tape, and in addition there is also a slight saving of line time (about 5 per cent.)
>
> "On heavy traffic loaded circuits, however, Page printing is best. For example, the New York-Boston circuit operates quad duplex at 50 w.p.m. per channel. Now at this rate the operators could not keep pace if required to gum tape. Moreover, the transmitting operators would find it difficult to feed the transmitter if given no assistance. With Page printers the receiving operators are able to sign the outgoing messages and so help the senders."

"M. Montoriol seems to think that the Western Electric is tied up with page printing. (This is a reference to the new volume written by M. Montoriol of which a review appeared in our last issue.—ED.) As a matter of fact we can use Baudot *traducteurs* but we do not want to do so, because these instruments 'space' after the shift signals and therefore cannot print mixed groups of letters and figures exactly as handed in by the senders. . . . It was stated in the T. AND T. JOURNAL that the Western Union were turning to tape printing or that there is a tendency to do so. The fact is that the latter

Digitized by Google

company believes that tape printers would be useful on their slow speed, long-distance circuits. . . . The French engineer appears to think that because the Western Electric only operates on Duplex circuits it is at a disadvantage. I believe if the Baudot could not be duplexed its use in England would still be confined to the Anglo-Foreign circuits. All Inland circuits utilise duplex so that the French impression that quadruple *simplex* is superior to Double *duplex* is apparently not shared in this country. The W.E. realises that nobody would operate a circuit simplex when the traffic carrying capacity can be practically doubled by using the duplex balance.

Mr. W. T. Hunter, telegraphist of Deal Post Office, and Amateur Golf Champion, is now in the United States, having resigned his position in the British Government Telegraph Service. Prior to leaving England he went round the Walmer and Kingsdown course in the excellent score of 67, thus beating the record he himself set up last year, by one stroke.

Mr. Lecomte, one of the steadily diminishing number of the late Submarine Telegraph Co., retired upon reaching the age limit a few weeks ago, when he was presented with a time-piece by the members of the staff as a souvenir of his long association with the Telegraph Service and a token of the unfeigned respect in which he is held by his colleagues, staff and supervisors alike.

The promotion of Mr. R. H. Hatswell of the Secretary's Office to Staff rank is an event which cannot be allowed to pass without a word or two of hearty congratulation. This is mingled with the sincerest and keenest regret that this well-deserved advancement should involve a severance of close official association with the foreign telegraphs.

With Mr. Hatswell's practical knowledge of telegraphy learnt—dare it be stated how many years ago?—there has always been a sympathetic understanding of the special difficulties associated with this particular arm of the Service which have rendered decisions wise and instructions particularly helpful. It is hoped that if officially we may be compelled to lose touch with a much respected administrator at least the Fates will be kind enough to permit a glimpse of certain of his activities through *St. Martins*.

It was with something approaching a sense of horror that the C.T.O. received the news of the terrible and fatal accident which befell their colleague, Miss M. Hodgson, while cycling. Miss Hodgson was an expert cyclist and was well-known in cycling circles as an excellent organiser in matters appertaining to cycle club life. Her withdrawal from this field of activity in any ordinary circumstances would have been met by unfeigned expressions of regret. The tragic end of our much respected colleague left little that we could do to soften the blow for her sorrowing relatives. That little was done. Fifty cyclists followed at the funeral and many wreaths from allied cycling clubs were reverentially laid upon her last resting place.

J. J. T.

LONDON ENGINEERING DISTRICT NOTES.

C.T.O. Section.

ON Saturday, Sept. 3, the Mechanicians and Linemen of the C.T.O. Section held their annual outing at picturesque Haslemere in Surrey. The journey was made by motor coach. After lunch a sports meeting was held. Some very fine running and close finishes were seen, and the friendly rivalry was capital to witness. After the sports, the prizes were presented to the winners by Mr. Bang, Y.Y., an engineer of the Chinese Telegraph Administration, Pekin, and a temporary member of the C.T.O. Section staff. He congratulated the winners, and assured the party how delighted he was to be with them, and to see the manner in which they took their recreations and sports. After tea the party left Haslemere at 6.30, and journeyed to Esher, where a concert was held. Among those who contributed to the evening's entertainment special mention must be made of Messrs. Coombe, Houghton, and Kennedy for their performances on piano, banjo, and mandoline, and of Mr. B. Wright, sen., in his rendering of "Our Cat." Mr. Bang recited, both in Chinese and English, some ballads written by a great Chinese poet. Leaving Esher at 9.30, the party arrived at the C.T.O. about 11 o'clock, thus concluding what was unanimously agreed to be a most enjoyable day.

Opening of Grosvenor Exchange.

Another step in developing the Telephone system of London was taken on Sept. 3, when the New Grosvenor Exchange was put into commission.

The exchange is situated in South Audley Street, W., and has accommodation for 2,000 subscribers and 480 junction circuits. A total of 963 subscribers were transferred on the opening day, the change over being effected very smoothly. The installation of the plant and the cabling of the area were carried out by the District staff, and it is satisfactory to record that the usual high standard of workmanship was maintained. This new exchange will help to serve the southern portion of the Mayfair area. It will be remembered that the Langham Exchange was built to relieve the northern portion of the area.

London Toll Exchange.

The first of the Toll exchanges, if the temporary switchboard in G.P.O. South recently re-christened "Annexe," is left out of account, was duly opened for traffic on Aug. 27. For a number of reasons the opening of this exchange had to be a gradual process so far as the lines were concerned. Lines had to be intercepted and the back ends used for other circuits, and since it was important to retain the provincial lines in service until the moment of the change over, a close working arrangement between the traffic and engineering officers at Toll and the provincial engineers was necessary to ensure that lines were handled in suitable group order. During the week ending Sept. 17 out-going lines were connected and the exchange enabled to take traffic in both directions.

A full description of Toll appeared in the September TELEGRAPH AND TELEPHONE JOURNAL, and it was there shown that in a number of ways it was different from any other exchange. To the casual visitor it suggests the ordinary local equipment, but the absence of subscribers' lines, the very limited number of plug-ended junctions—and the concentration arrangements do not, on the other hand, reproduce the "Trunk" atmosphere. In-coming junctions from local exchanges are jack-ended.

Toll is, as it were, the half-way house between the bustling local exchange and the more deliberate Trunk Exchange.

Radiotelegraphy.

The enthusiasm of the staff and public regarding this rapidly developing science shows no sign of abatement and the number of experimental amateur installations authorised in this district now exceeds 1,300. The recent release from Post Office custody of several hundred packages of wireless apparatus to the owners, will probably increase the ever-growing list of searchers for signals from Mars.

Growth.

Recent returns indicate that the decrease in stations caused by the depression in trade and revision of rates has been arrested and the district figures which now stand at 158,761 exchange lines, 146,835 internal extensions, 10,134 external extensions, and 301,993 stations are going ahead again. These figures relate to the London Engineering District only, which does not coincide with the London Telephone Area.

Denman Sports Club.

Denman Sports Club, who after a lapse of five years, had a very successful football season for 1920-21, when they won Stamford Hill League, Div. II's Cup and Medals, have once again kicked off for what they hope will be as successful a season as last. This season, they have entered for the London Junior Cup, Middlesex Junior Cup, and Tottenham Charity Cup, and have two teams entered for Div. 1 and 3 of the same League in which they were so successful last season. Any member of the staff in the City Engineering Branch wishing to join the above club will be heartily welcome. For further particulars apply: Hon. Sec., Football, W. F. Steers, 26, Thornham Grove, Stratford, E.15; or to Gen. Sec., Sports Club, E. Forsdike, 21, Pelham Road, Tottenham, N. 15. Other secretaries please note.

MR. G. DAWKES.

Mr. G. DAWKES retires from the Controllership, Telegraphs, Edinburgh. He has had a varied career. He was Inspecting Telegraphist in the North-Eastern District, Travelling Clerk in the Surveyor's establishment; Chief Superintendent, Telegraphs, Leeds; Assistant Traffic Manager, G.P.O., and then Controller, Edinburgh. In so varied a career Mr. Dawkes met a large number of the officers of the Post Office, and it is not too much to say that he attracted very genuine respect and esteem. He had travelled the whole country and seen the working at most offices, and he never confused constructive criticism with censoriousness and never failed to appreciate the difficulties which often are better known locally than to visiting officers. At Headquarters during the war he was identified with many changes which had to be swiftly made, and he carried them out with the least inconvenience and disturbance to others. He was full of considerateness, and singularly able to fulfil his duty with enthusiasm while retaining the insight which prevented him from appreciating other points of view.

A warm supporter of the Telegraph Messengers' Institute, he identified himself with the messengers in all their various activities. To mark their appreciation of Mr. Dawkes the inspectors and messengers presented him with a solid silver rose bowl, Mrs. Dawkes at the same time receiving a basket of flowers.

The Telegraph staff and the heads of the various Departments in the General Post Office gave him a handsome tea service, and Mr. Prescott, Superintendent, Telegraphs, who made the presentation, drew attention to the fact that, although Mr. Dawkes had only been Controller for six years, these years had probably been the most strenuous of his official career. He spoke with confidence of Mr. Dawkes' unsparing labours during the war period, and how keen was his desire that the Telegraph Department should always be in a position fit to meet any of the requirements that might be made by the Naval and Military Authorities. In the name of the subscribers he wished Mr. and Mrs. Dawkes all good wishes and the best of health.

Mr. Dawkes in a few words thanked all the subscribers for their good wishes, which he reciprocated to the full.

LONDON TELEPHONE SERVICE NOTES.

London Telephonists' Society.

THE first meeting of the Session takes place on Wednesday, Oct. 5. The president is Mr. M. C. Pink and the subject of his address is "The Future Development of the Telephone Service."

Telephone and Telegraph Society.

The programme for the coming session is a particularly interesting one. The president is Mr. F. J. Brown, C.B.E., Assistant Secretary, Telegraphs, who will open the session with a paper on the subject of Imperial telegraph communications, a subject of peculiar interest at the present time in view of the discussion which has raged round it at the recent Imperial Conference. An original feature of the programme is four papers by prominent members of the Union of Post Office Workers. The authors and titles are:

Mr. A. C. Winyard, "Possibilities of Post Office Development."
Miss A. Flanagan, "The Telephone Service: Suggestions for Improvement."
Mr. E. J. Lansbury, The Night Telephone Service and some of its Problems."
Miss L. M. Herring, "Women as Civil Servants."

The paper by Mr. Bernard Chapman entitled "Public Intelligence" should attract a good audience in view of the controversy which has taken place in the Press on the Civil Service generally, and on the Post Office in particular. It is believed that Mr. Chapman will not take the title of his paper too literally, but will deal rather with the subject of the education of the public (and incidentally the Press) through the Press. Before coming to the Post Office Mr. Chapman had experience in the matter at one of the war-time Ministries.

Papers of the more highly technical nature are only two in number. One is by Mr. H. H. Harrison of the Automatic Telephone Manufacturing Co., whose subject is "Printing Telegraphy in America" and the other is entitled "High-frequency circuits," by Mr. A. B. Hart, who is so well known to all members of the Society.

The meetings take place at the Institute of Electrical Engineers, Victoria Embankment, on the third Monday in each month (except the April meeting which will be held on the fourth Monday) so that the session opens on Monday, Oct. 17.

New Exchanges.

September has probably created a record so far as London is concerned in the opening of new exchanges. Grosvenor was opened on the 3rd, Toll which was opened partially in August will be in full swing from the 17th, and Minories opens on the 24th. Grosvenor Exchange is a relief to Mayfair and is situated in South Audley Street in premises which were formerly occupied by an antique dealer. In one of the rooms is a valuable fireplace which however is boarded up to prevent damage; 24 A and 10 B positions have been installed. Minories Exchange is located in a bungalow building in Mansell Street, near the Tower Bridge, and serves to relieve Avenue. Its equipment embraces 35 A and 15 B positions.

Conscience Money.

A postal order for 3*s.* 6*d.* was received recently enclosed in a letter card with the advice "3*s.* 6*d.* for directory from a call office." The sender apparently appropriated a stiff covered copy of the directory from a call office and satisfied his conscience in this manner.

West Traffic District.

ON Sept. 1 the West Traffic District held their Swimming Gala at St. George's Baths, Buckingham Palace Road. The baths were well filled with enthusiastic spectators and competitors and a great evening's sport was provided. There were about 100 entries for the 11 competitive events, and in addition there was an exciting water polo match, a display of high and fancy diving, and a very fine display of ornamental swimming by the Misses Elliott, three in number, who demonstrated how apparently simple it is to combine gracefulness with dexterity.

The competitors from the various exchanges had no grounds for complaint that their supporters did not cheer them on, for the noise made by the "fans" (if the ladies will excuse this Americanism) was really deafening. The presence of water and a bath seems to have an irresistible influence on mankind, causing him to exercise his vocal cords, witness the strange noises emanating from the bathroom when the man in the house has his morning shave. Whatever the cause the effect was produced to perfection at St. George's Baths.

The principal events and results were:—

Supervisors' Handicap.—Miss Money (G) first. Miss Tripp (VI) second.

Invitation Team Race.—Regent Exchange (Misses Cole, Williams, Amos, Phipps) first. Gerrard Exchange (Misses Roblon, Burt, Wilson, Davis) second.

Engineers' Handicap.—Mr. Wilks (G) first. Mr. Warren (RE) second.

100 *Yards' Championship* (Western District).—Miss A. Phipps (RE) first. Miss E. Williams (RE) second. Miss Amos (VI) third.

Diving Championship (Western District).—Miss Davis (G) first. Miss Phipps (RE) second. Miss Williams (RE) third.

At the conclusion of an eventful evening the prizes were presented to the winners by Mrs. Pounds who thus brought to a fitting conclusion the gala which was under the direction of Mr. E. A. Pounds, whose penchant for seeing these things through is too well-known to be enlarged upon here.

Trunk Exchange.

The Imperial Swimming Club, in connexion with the Trunk Exchange, held a very successful gala at Holborn Baths on Wednesday, Sept. 14. Much enthusiasm was shown by the audience throughout the evening. This year's learners' race of 1 width, 5 competitors entered, two of which were able to compete for the Needle and Thread race, 2 widths.

The winners of the following races were:—

Learners' Race (1 width).—Miss Parker first. Miss D. Pearce second.

Needle and Thread (2 widths).—Miss Coller first. Miss Peto second.

Graceful Swimming (Breast stroke).—Miss Harold first. Miss G. E Sutton second.

In the 100 Yards' Championship Miss L. K. Davies was returned as champion, and Miss Powell second. The competitors for the 60 Yards' Invitation Handicap open to all Postal Service resulted in a large number of entries. The winners being Miss Bishop (Centels), first; Miss Bleach (London Wall), second. Miss Phipps (Regent), third.

Great amusement was caused by the Old Clothes Race, the dressing of the competitors and the comical way in which they entered the water proved that they were out to entertain the audience, and judging by the uproar of laughter, their efforts were not in vain.

A splendid display of diving was given by the Amateur Diving Association, and great appreciation was shown when the Royal Life-Saving Society exhibited their different methods of saving life.

The Polo match was played between the Metropolitan Police ("F" division) and the Star Athletic, the latter team being the winners.

The day following the Trunk Gala application was received for 40 tickets for the coming L.T.S. Gala on Oct. 7, thus proving the great success of the evening.

City Traffic District.

The staff of the exchanges in the district subscribed the sum of £50 towards the cost of a holiday camp for boys drawn from Canning Town. A "Special Commissioner" visited the camp and in his extremely picturesque report which is reproduced below, he tells how well the money was spent.

I located the Fairbairn House Boys' Camp on what is known as the Pett Level between Winchelsea and Rye at a spot which I afterwards found to be the bed of the one-time harbour of the Cinque Port of Winchelsea. There were 85 boys in camp, all fit and strong and thoroughly enjoying themselves, and some 10 grown ups, which number included the Warden of the Mansfield House Settlement and his wife (Mr. and Mrs. Reade), who were engaged in doing practically all the work of the camp, leaving the boys to partake to the full of the joys of the seaside, &c. Mr. Moon was the C.O. of the camp and Mr. Gunter his second in command.

A description of a day in camp as I saw it would perhaps convey to you an impression of the life which the boys lead. I will take last Sunday. Somewhere between 8 and 9 a.m. we arose from Mother Earth, not to a blare of trumpets or piping of whistles but each one at his own sweet will. About the latter hour a clatter of plates and mugs signified that the lads were ready for breakfast. They lined a convenient bank and were ready to enter the tent when a mariner, equipped with bell-bottomed trousers and earrings, asked for the services of the lads in launching his fishing smack which had been left high and dry on the shingle by an inexperienced hand. A few minutes tramp across the shingle and over the sea wall brought us to the derelict. Ropes were attached to the forepart of the keel and the lads were soon hauling and pushing with might and main. She took the water more like a rhinoceros than a swan but that mattered not to the lads of Canning Town to whom a launching of any description was a unique experience. Breakfast was now the more acceptable. It consisted of porridge, with sugar and milk, bread and butter and tea. Like little Oliver, of whom they all seemed to have heard, they came for more—and got it.

After a short service, shop was opened and we sold chocolate, apples, caramels, nuggets (nougat), ginger beer and stamps. Some of the purchases we "put on the slate" until the morrow when the bank was opened. This bank contains the savings which the boys have accumulated, penny by penny, during the preceding months and during camp it is opened on week-days so that the boys can draw out what they require. At post time some of the lucky ones received postal orders which they desired either to turn into cash, apples or sweets, immediately or to put in the bank. Shop over, we scrambled down to the sea and had a glorious bathe.

Dinner, consisting of cold roast mutton, potatoes, marrowfat peas, boiled rice and jam, which had been cooked by "old Tom" who among other articles of clothing sported a "rugger" jersey and a cricket cap, was disposed of and one small basket would have held all the remnants.

After tea we visited the ancient church at Winchelsea where the Vicar preached a short homely sermon to the boys, and after the service explained to them the antiquities of the Church. The boys proceeded home

Digitized by Google

independently and from the hill we soon saw them dotted over the plain in all directions, some hurrying, some daudling and some gathering pokers from the rush beds in the dykes.

After supper and a sing-song I was "told off" to see No. 9 tent to bed, and my 13 lads soon had their ground sheets down and crept into the sleeping bags, a sewn-up blanket which their mothers had provided for them, and after I had tucked a blanket round each three and slacked off the tent ropes, I said "Good night" feeling that we all had had a good day.

At teatime on Monday, the last meal I attended, Mr. Moon explained to the lads that it was owing to the kindness of the ladies in the City District that it had been possible to extend the camp to a fortnight and the lads expressed their thanks in a way in which only boys can—the marquee pole nearly came down. I had a great "send off" which I shall not forget in a hurry, but I realise that it was not so much for me as an expression of thanks to those whom I unworthily represented.

Mr. Moon explained to me that each lad pays something towards the camp expenses and is assessed according to what his parents can afford to pay. All grown up engaged in running the camp pay their full share of the expenses. The railway fare for the return journey is at the special rate of 6s. per person and all other money is spent in hiring camp equipment and providing food. The lads are wholesomely but not sumptuously fed and their appearance and cheerfulness shows plainly how much they have benefited by the holiday. I was assured by Mr. Reade that the extra week which the subscriptions of the City District has made possible will make all the difference to the benefit derived from the camp. The campers had only one regret and that was that it was not possible for some of the ladies who had subscribed to visit them.

BRIGHTON.

SUNDAY, Sept. 4, will stand as one of the most memorable dates in the annals of the Brighton Post Office.

The unveiling of the office War Memorial, which took place on that day, was a ceremony deeply reverent, of simple dignity, indescribably impressive; and of a significance that must have engraved itself on the hearts and minds of everyone present.

The sympathy exhibited by the presence of so many controlling officers, together with a large number of retired members of the staff, was keenly appreciated. To the staff, the occasion presented homely aspects, and they were as one great family with the relatives of the departed; all sharing their sorrow and their pride.

The Postmaster of Brighton (Mr. J. F. Horn), who unveiled the Memorial, recalled how 577 Postal Servants in the Brighton district responded to the country's call, and that of this number no fewer than 63 made the supreme sacrifice. Continuing, he said: "Our every-day struggle for existence tends to make us selfish. In our homely way we call it "looking after number one," and are somewhat inclined to regard it as a virtue. But it is on occasions such as this that deep down in our hearts, if not with our lips, we admit the meanness of this view. The action of these dead comrades contains no suggestion of looking after number one; we know that they did their bit willingly without any selfish motive. Some of us who remained at home might ask ourselves whether we were entirely free from selfishness; and all of us who remained at home owe to these dead men and to others whose lives were forfeited in the defence of our country, a debt of gratitude quite beyond our power to repay. Into the Great Beyond these men have passed bearing with them evidence of their worth and marks of wounds and suffering; evidence, dumb but eloquent, of a burden borne; a duty done."

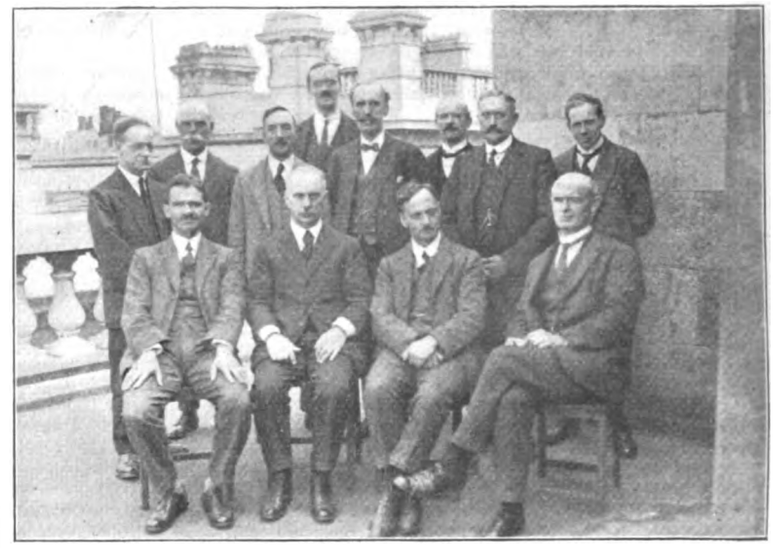
In the unavoidable absence of the Vicar of Brighton, the Memorial was dedicated by the Rev. Canon Burton, O.B.E., who served with distinction during the war.

Prior to the formal dedication the Canon delivered a brief but impressive address, emphasising the same need for unselfishness in everyday life as displayed by our fallen comrades.

During the proceedings, the solo "Abide with me" was finely rendered by Mr. R. Dandy, whose voice was heard to advantage in the large office, after which the whole company sang the hymn "O God, our help in ages past," though it was noticed that many could not join in owing to their emotion, and a conclusion was reached by the sounding of the "Last Post" by trumpeters of the R.F.A., and the singing of the National Anthem.

From first to last the one right note was maintained, and for the arrangements the utmost credit is due to Mr. Gilder, the Honorary Secretary to the Roll of Honour Committee.

The Memorial took the form of a plain oak panel enclosed in a finely designed frame with Corinthian columns and capitols. The beautiful carving of the inscription and names of the fallen was the work of Mr. Perry Hill, of the Brighton School of Art, and the frame was very kindly presented by Mr. Frank Trill, who was a temporary employee at the Post Office during the war.



THE CENTRAL TELEGRAPH OFFICE SECTION, LONDON ENGINEERING DISTRICT.

G. F. GREENHAM AND P. G. HAY.

IN last year's September and October issues of this JOURNAL some details of the London Engineering District were given in which it was stated that the work of the district is organised on functional lines and consists of fourteen sections. The bulk of the work in 13 of these sections has to do with the telephone service, although the Engineer in most cases is responsible for the telegraph plant in his section. There is one section, however, in which the bulk of the work has to do with the telegraph service. This section, known as the C.T.O. Section, because the Central Telegraph Office provides the bulk of its work, does however, include some telephone plant, as will be seen later.

The equipment and maintenance of the vast amount of apparatus contained in the Central Telegraph Office, the largest of its kind in the world, is a task of no mean order. For the benefit of those who are not familiar with this hive of industry in St. Martins-le-Grand, in the building known as G.P.O. West, a brief outline of some of its salient features will be given.

The instrument rooms occupy three floors usually referred to as galleries. Speaking broadly one gallery is allotted to foreign circuits, one to provincial circuits, and one to Metropolitan circuits.

THE SECTIONAL ENGINEER, MR. STEED, AND HIS PRINCIPAL OFFICERS.

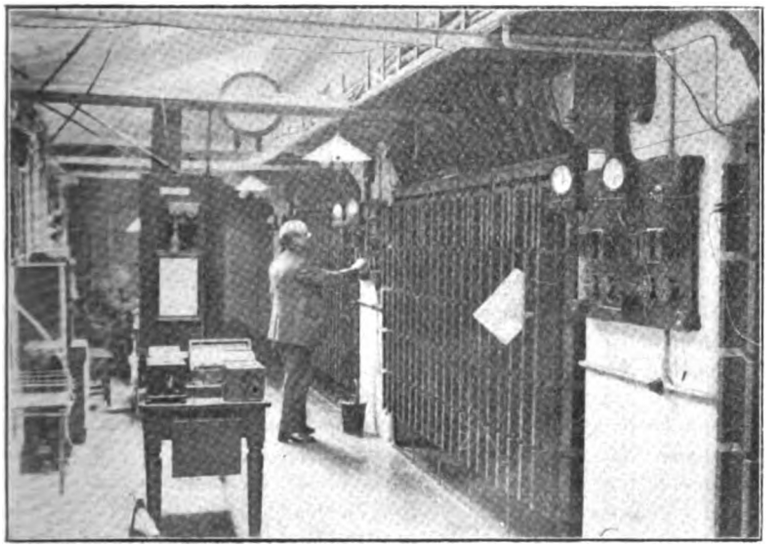
In the last named are found nearly the whole of the circuits serving the Metropolitan area, but also a number of those to the Home Counties. Although some of the lines terminate on apparatus special to them yet the majority are connected to the intercommunication switchboard. This switchboard serves a somewhat similar purpose as a multiple telephone switchboard of the C.B. type, and contains many features incorporated in the latter. Battery power is concentrated at the C.T.O., thus simplifying the plant at the distant stations. The introduction of this switchboard in 1902 resulted in considerable economies both in plant and personnel. There are about 1,200 circuits connected with it. By its aid one Metropolitan Office can be connected direct to any other office so that re-transmission of telegrams is avoided and the circuit time correspondingly reduced. There are a number of instruments connected with the switchboard for the purpose of receiving messages from stations connected with the switchboard for transmission to other stations not so connected and *vice versa*. The method of working is briefly as follows:—a call from an out office is indicated by the glowing of a small filament lamp on the switchboard. The operator by means of plugs and cords transfers the calling circuit to an idle apparatus set if the telegram is for the provinces or local delivery; if for another Metropolitan Office the two are connected direct at the switchboard by the operator. On the completion of a transmission, clearing lamps on the switchboard are made to glow and normal conditions are resumed by the operator withdrawing the plugs.

All the circuits connected to the Metropolitan switch are worked manually, the familiar hand-operated key and sounder being used in all cases.

As is generally known, however, machine telegraphs are used on important long-distance lines.

Machine telegraphs generally speaking are designed to permit of messages being transmitted at a greater speed and with more precision than is possible by manual working and are, as the term implies, largely mechanical in their functions.

Modern machine telegraphs can be broadly divided into two classes, viz., apparatus used for high-speed working and that used for Multiplex telegraphy



Digitized by Google

Transmission is effected by means of currents sent out either directly by the operation of a keyboard or automatically with the aid of a specially prepared tape, which is perforated in accordance with the particular system in use, and which is passed mechanically through an automatic transmitter within which certain electrical contacts are made in accordance with the perforations in the tape.

High-speed telegraphy in which speeds of the order of 400 words per minute can be attained is effected by means of an automatic transmitter used in conjunction with a perforated tape.

The tape is perforated either manually by feeding it through a 3-key device, the keys being hit by strikers held in the operator's hands, or through a machine fitted with a keyboard similar to that on a typewriter. In the latter the depression of a key sets up electro-magnetic action, which results in the appropriate perforations being made in the tape.

In addition to the purely mechanical perforator in which the punches which perforate the tape are operated in suitable combination by the 3 keys there are punchers in which the keys control punches worked by pneumatic power. One type of pneumatic puncher is capable of perforating as many as 8 tapes by one operation. This is helpful when messages, principally for the Press. have to be transmitted simultaneously to different parts of the kingdom. The keyboard perforator can be operated at a much higher speed than the 3 tapper device. moreover its operation does not necessitate a knowledge of the Morse code.

T.S.B.

High-speed transmission naturally necessitates automatic apparatus for receiving. Various types of high-speed receiving apparatus have been designed capable of recording the received signals direct on a paper tape and more recently by perforating a tape to correspond to the perforations on the tape at the transmitting end. The latter can be used for re-transmitting the received messages to other stations by means of automatic transmitters or for printing the messages by passing the tapes through automatic printing apparatus. The receiving perforator and its associated printer are actuated by an ingenious combination of electric and pneumatic power.

Multiplex machines are designed to cope with a problem entirely different to high-speed transmission between two points, namely, the multiplication of the number of traffic channels which can be established on one telegraph line.

This object is effected by means of two distributors to which the line is connected, one being placed at the up and the other at the down office.

These distributors connect the line, both for sending and receiving purposes, to several operators in rotation so rapidly that to all intents and purposes the stations are enabled to work simultaneously. Clearly each operator must send only during the periods in which the line is associated with his set. The operator is made aware of the psychological moment in each revolution of the distributor by an electro-magnetic tapper.

Naturally, the distributors at the two ends of a line must work in synchronism, and this is assured by various electrical devices.

Transmission from each station is effected under one system directly from a keyboard, and under another indirectly by passing specially perforated tapes through transmitters of a particular type, with which are associated keyboard perforators for preparing the tape.

In the case of the direct keyboard system the messages are recorded on a paper tape by a type wheel and in the other system a tape is perforated by the receiver identically with the transmitting tape, and is then passed through a translator which typewrites the message on a form. In the Provincial and Foreign Galleries at the Central Telegraph Office many types of telegraph printing or recording apparatus are in use. As may be imagined such a vast quantity of complex apparatus as is in use in the galleries requires the care of a skilled mechanical staff to keep it in an efficient condition. The commercial staff includes officers known as dirigeurs, whose duty it is to perform small acts of adjustment, but a number of officers attached to the engineering staff are in constant attendance to deal with circuit faults and troubles beyond the power of the dirigeurs to handle. The upkeep of the apparatus requires the assistance of a staff of skilled mechanics who are accommodated in two workshops on the premises, and are unfortunately through the exigencies of space, somewhat cramped.

In spite of severe limitation of space it has been found possible to provide the shops with such useful equipment as power-driven lathes and drills, and specially designed testing sets to enable troubles in the complicated apparatus to be rapidly located and to simplify adjustments.

The circuits to each gallery at the Central Telegraph Office pass through main and divisional test boards located in the gallery. These testboards are so arranged as to provide the commercial staff with facilities for testing lines, the localisation of faults, and for arranging the lines and apparatus to suit the ever changing traffic requirements.

All circuits entering the building pass through a main distributing frame situated in a room in the basement, which is under the sole control of the engineering staff. This room is known familiarly as T.S.B. The main frame is fitted with the usual protective devices, and a test jack is associated with every line.

(To be continued).

CRICKET.

"CENTELS" *v.* SECRETARY'S OFFICE.

Played at Dulwich on Wednesday, Sept. 7, 1921.

Secretary's Office.		*Centels.*

BOWLING :—Wilmot, 1 for 22; Randall, 4 for 51; Cook, 2 for 45; Smith, 1 for 8; Minhinnick, 2 for 5; Banks, 0 for 19.

BOWLING :—Reed, 1 for 62; Hurford, 0 for 30; Cove, 3 for 42; Young, 0 for 25; Peel, 1 for 15.

The above score speaks for itself. What is perhaps of even more value was the happiness of the occasion. One of the superior officers of the Central Telegraph Office had befriended us by obtaining the loan of the Dulwich ground. Both sides were accompanied by friends, Mr. Leech, Assistant Secretary, being the chief representative of the Secretary's Office. Rival, but not ungenerous applause marked various achievements, and proud as the C.T.O. is of its victory, it is almost as proud of the fact that Mr. Cook's wicket —a valuable wicket, seeing that Mr. Cook is a Surrey County player — was obtained by Mr. Peel. It was a happy commingling and our respect for our Chiefs in the Secretary's Office is not lessened by the fact that we beat them at cricket, but it is heightened by an intimacy of intercourse which comes too rarely.

J. L.

RETIREMENT OF THE SUPERVISOR OF EDINBURGH CENTRAL EXCHANGE.

MISS AGNES ST. CLAIR JOHNSON, the Supervisor of Edinburgh Central Exchange, has just retired at the age limit. Miss Johnson has spent her whole life in the Edinburgh Telephone Service, and she has been the Chief Supervisor of the Central Exchange since it was opened about twenty years ago. Her retirement will be a great loss to the service and the Edinburgh public, for whom Miss Johnson has done much, will miss her.

Miss Johnson has always been a woman of phenomenal energy and enthusiasm, and to the end of her service her activity never flagged, nor did her interest in her work diminish. Since 1912, when the telephone system was transferred to the Post Office, Miss Johnson has served the public with the same thoroughness she displayed in the service of the National Telephone Company.

Digitized by Google

Miss Johnson insisted on the same high standard of duty in others she set for herself, and it can be truly said that if she closely kept her staff to their work no one of them worked harder than she did. She had no patience with indifference to duty, but her sympathy and help to members of her staff in times of trouble were as liberal as her enthusiasm for efficiency was marked.

For the high standard of telephone service always given in Edinburgh the public have largely to thank Miss Johnson, and now that she has gone into retirement many subscribers will miss her courteous and kindly way of accepting a complaint or smoothing over a difficulty.

MISS AGNES ST. CLAIR JOHNSON.

To those of her colleagues who knew her well Miss Johnson was an inspiration as she was a direct challenge to those who are unable to associate enthusiasm, alertness, and initiative with the servants of the State.

Even when away from duty, Miss Johnson kept in close touch with the working of the exchange at times of emergency. During the war her loyalty in this way was of inestimable assistance, for she was ever ready to give her advice and assistance to those who required it.

Before leaving Miss Johnson received a handsome testimonial from the staff in and around Edinburgh, and she goes from the service with that respect and esteem which it is never possible to withhold from those who throughout their lives put duty before everything else.

CALENDAR OF COMING EVENTS.

Oct. 5.—London Telephonists Society. Presidential address by Mr. M. C. Pink, "The future development of the Telephone Service."
„ 7.—L.T.S. Swimming Association. Grand Water Gala, Great Smith Street Baths, Westminster, 7 p.m.
„ 29.—City Traffic District, Dance at Australia House. Tickets can be obtained from members of the staff at Bank, Central, City, or Trunk Exchanges.

PERSONALIA.

LONDON TELEPHONE STAFF.

The following resignations took place on account of marriage:—

Miss B. M. ALTON, Assistant Supervisor, Class II, of Trunk Exchange.
Miss I. E. BILES, Assistant Supervisor, Class II, of Trunk Exchange.
Miss M. D. EDWARDS, Assistant Supervisor, Class II, of Park Exchange.
Miss L. G. BROWN, Assistant Supervisor, Class II, of Holborn Exchange.
Miss F. M. WEEKS, Assistant Supervisor, Class II, of Museum Exchange.
Miss C. K. A. WOOD, Assistant Supervisor, Class II, of Victoria Exchange.
Miss L. M. SCHOFIELD, (Tel. on Allce.), of Hammersmith Exchange.
Miss A. G. WINDALL, Telephonist, of Trunk Exchange.
Miss W. M. AVERILLO, Telephonist, of Trunk Exchange.
Miss M. BRANNIGAN, Telephonist, of Trunk Exchange.
Miss A. S. WRIGHT, Telephonist, of Park Exchange.
Miss B. R. POLLARD, Telephonist, of Holborn Exchange.
Miss A. E. BEARD, Telephonist, of Museum Exchange.
Miss E. L. ABBOTT, Telephonist, of Museum Exchange.
Miss O. G. GAIT, Telephonist, of Museum Exchange.
Miss D. DOWDY, Telephonist, of Museum Exchange.
Miss E. GIBBS, Telephonist, of Victoria Exchange.
Miss A. R. MOORE, Telephonist, of Victoria Exchange.
Miss M. M. LOFTS, Telephonist, of Victoria Exchange.
Miss E. M. GILES, Telephonist, of Victoria Exchange.
Miss N. LYNES, Telephonist, of Victoria Exchange.
Miss H. M. MITCHELL, Telephonist, of Avenue Exchange.
Miss A. BURNHAM, Telephonist, of Avenue Exchange.
Miss E. GITTINGS, Telephonist, of Avenue Exchange.
Miss L. WILLINGALE, Telephonist, of Avenue Exchange.
Miss E. E. L. DAY, Telephonist, of Finchley Exchange.
Miss C. HOCKADAY, Telephonist, of Paddington Exchange.
Miss E. M. HARPER, Telephonist, of Paddington Exchange.
Miss H. GOULD, Telephonist, of Paddington Exchange.
Miss D. E. TERRY, Telephonist, of Streatham Exchange.
Miss E. M. GRACE, Telephonist, of Streatham Exchange.
Miss B. L. ELLIOTT, Telephonist, of Chancery Exchange.
Miss A. L. SKELTON, Telephonist, of Wimbledon Exchange.
Miss I. F. RAWLINGS, Telephonist, of Central Exchange.
Miss G. O. WERNHAM, Telephonist, of Central Exchange.
Miss M. E. AUSTIN, Telephonist, of Gerrard Exchange.
Miss E. MCGINNESS, Telephonist, of Gerrard Exchange.
Miss E. A. MOORE, Telephonist, of Gerrard Exchange.
Miss M. R. ROBINSON, Telephonist, of Gerrard Exchange.

PROVINCIAL.

Plymouth is pleased to place on record the promotion of Miss E. E. WESTLAKE from Assistant Supervisor, Class II, to Assistant Supervisor, Class I.

Miss M. THOMAS, Telephonist, Devonport (Plymouth), resigned on July 30 for a life partnership with Mr. J. Richards, Telegraphist, Devonport. They were presented with stainless cutlery and a plated teapot by their respective colleagues.

Miss G. BERWICK, Telephonist, Plymouth (formerly Telephonist, Cambridge), was presented by her colleagues with stainless cutlery upon her resignation on Aug. 20.

Miss O. FOSTER, Telephonist, Plymouth, resigned on July 27, in view of her approaching marriage. She was presented by her associates with a handsome plated spirit kettle.

Miss F. E. KELLOW, Telephonist, Plymouth, who resigned for marriage on Sept. 9, was presented by her colleagues with a set of cutlery.

IMPERIAL TELEGRAPH COMMUNICATIONS.*

IF its system of transport—communication by road, rail, canal, sea and air—may be described as the circulatory system of the community of nations known as the British Empire, telegraphic communication may be described as its nervous system. Both are necessary for its very existence; and an efficient system of telegraph communication—speedy, reliable and cheap—is necessary for its intelligent and well-ordered development. Anyone who contributes towards the practical working of such a system, whether by devising and planning it, or by its actual administration and operation when it is already in existence, deserves well of the Commonwealth. He is an Imperialist in the true and worthy sense of the word.

The Empire system of telegraphs before the war was the admiration and envy of the world. Other powers—Germany, France, the United States—had set out to emulate it, but they were still far behind. It had its critics, and some of the defects they pointed out were real; but it stood the test of the Great War, and although that time of stress and testing left its marks upon it—marks which have not yet disappeared—it was and still remains a more efficient system of communication that any other, and one of which the Empire may well be proud.

The cable system of the Empire is mainly the result of private enterprise. British technicians and British capitalists were pioneers in the making and laying of cables; and it may safely be said that British makers of submarine cables still lead the world.

To give a very brief and imperfect historical résumé. The projectors of trans-oceanic telegraphy appear to have been the brothers Brett in 1845. Cyrus Field, an American, endeavoured to interest British enterprise in a trans-Atlantic project in the fifties, and thanks largely to his efforts a company was formed, a cable was made, and an attempt to lay it began in 1857. The cable broke 300 miles from the Irish coast, however, and the attempt was abandoned until the following year. After several attempts in 1858, the cable was actually laid, and communication was established for a few days, congratulatory messages passing between the Queen and the President of the United States; but signals grew faint and soon disappeared owing to defects in the manufacture of the cable. Another attempt was made in 1865, but again proved a failure, the cable being abandoned in the Atlantic; and it was not until 1866 that success was finally achieved. These early cables ran between Ireland and Newfoundland, and the heavy cost was borne by the Anglo-American Telegraph Company—a British Company. Altogether it owns four abandoned cables across the Atlantic, and five which are still working.

It is interesting to note that a good deal of apparently instructed scientific opinion maintained that cable communication across the Atlantic was impracticable. In particular, the famous Robert Stephenson said with reference to the 1858 project that failure was inevitable. Such prophecies may encourage those of us who believe in the practicability of projects which even contemporary experts consider impossible—though the achievements of recent years have made the pessimists somewhat chary of speaking too positively of the impracticability of anything.

The first attempt to lay cables to the East was made in 1859 down the Red Sea and along the coast of Arabia to Karachi. This attempt was made by a private Company under guarantees from the Government, but the cables worked for a few days only, and were afterwards abandoned. The attempt was not repeated until 1868-9, when seven companies were started which subsequently became merged into the Eastern and Associated Companies. They were the—

Anglo-Mediterranean,
Marseilles, Algiers and Malta,
Falmouth, Gibraltar and Malta,
British Indian Submarine,
British Indian Extension,
British Australian, and
China Submarine.

These were reconstituted as the Eastern and Eastern Extension Australasia and China Companies in 1872-3.

South Africa was connected in 1879 by means of cables down the east coast of Africa; and in the intervening years, and later, numerous cables were laid throughout the whole system in duplication of the original single lines.

The West Indian Colonies were connected up in 1870.

The Pacific cable—the State-owned route between Canada and Australasia—was opened in 1902.

Without proceeding further with our historical retrospect, we may now consider the present position of cable communication throughout the Empire.

First, as regards the North Atlantic, there are 14 cables between the United Kingdom and North America, all of which land either in Newfoundland or Canada. Of these 8 are controlled by the Western Union Company and 5 by the Commercial Cable Company—both United States Companies. One of the 8 controlled by the former is the cable which formerly belonged to the so-called Direct United States Cable Company, a company which despite its name was a purely British concern. This cable, which runs from the south-west of Ireland to Newfoundland, thence to Halifax, and thence to Rye Beach in the United States, was bought by the Post Office last year, but has continued to be leased to the Western Union Company under an Agreement terminable at short notice. Three of these cables run from Cornwall. The remainder

* A paper read before the Telephone and Telegraph Society of London on Oct. 17, 1921, by Mr. F. J. Brown, C.B.E., Assistant Secretary for Telegraphs.

Digitized by Google

start from the south-west of Ireland, with connexions to London by means of short cables to Cornwall or Weston-super-Mare—alternatively by Government landlines. Their termini in Newfoundland or Canada are connected by cables or landlines with New York. The bulk of the traffic which they carry—probably five-sixths at least—is to and from the United States, but they are of course all available for communication with Canada, and through Canada with Australasia by means of the Pacific Cable.

So far, I have described 13 cables only. The remaining one is the Imperial Cable, which runs from Penzance to Fayal in the Azores, and thence to Halifax, Nova Scotia. To this we will return later.

From Halifax a cable runs to Bermuda and thence to Jamaica: and Jamaica is connected with the principal British West Indian islands and British Guiana, *via* the United States islands of Porto Rico, St. Thomas and St. Croix. These West Indian cables are old. They are said to have been badly laid in the first instance, and they are very frequently interrupted. The West Indian cables beyond Jamaica are, indeed, the weakest spot in our Imperial communications, and are giving much concern to the Imperial Communications Committee—the Advisory Committee on telegraph communications which was established some 2½ years ago under the presidency of the Secretary of State for the Colonies, with representatives from the principal Departments of the State concerned in telegraph communications—Colonial Office, Foreign Office, India Office, Board of Trade, Treasury, War Office, Admiralty, Air Ministry, and—last but not least in this connexion—the Post Office. The present proposal is that a new cable should be laid from Bermuda to Barbados, Trinidad and British Guiana, if this can be done for a moderate subsidy; or failing this that communication between these points should be established by wireless telegraphy.

From Halifax, connecting with the Imperial Cable, also runs a landline, *via* Montreal, which connects with the Pacific cable at Bamfield, Vancouver. It is owned and maintained by the Canadian Pacific Railway along which it runs, but is leased and worked by the Pacific Cable Board.

The Pacific cable runs from Bamfield by a long stretch of nearly 3,500 miles—the longest stretch of cable in the world—to the lonely little island of Fanning, thence to Suva in the Fiji Islands, thence to Norfolk Island, where it bifurcates, one branch going to Auckland in New Zealand, and the other to Southport in Queensland. A cable owned by the Pacific Cable Board also connects Auckland with Sydney, so that there are two routes from Norfolk Island to Australia, one direct and the other *via* New Zealand.

To turn now to the Eastern and Associated Companies' cables. Five cables run from Porthcurno in Cornwall directly or indirectly to Gibraltar, whence they are continued by four cables to Malta, and thence again by five cables to Alexandria. There are numerous landlines across Egypt from Alexandria to Suez, whence four cables run to Aden. These lines from Porthcurno to Aden are the backbone of the system, and a strong backbone it is. At Aden the cables bifurcate, one route going eastward to Bombay or Colombo, and the other southward to Zanzibar. The eastward group is continued, partly by Government land-lines across India to Madras, and partly by cables, as far as Singapore, where the route again bifurcates, one line going to Hong Kong to serve China and Japan, and the other going southward to serve Australia and New Zealand, incidentally serving the Dutch East Indies on its way. This was originally the Companies' only route to Australasia; but some twenty years ago they laid an important new line of cables from Porthcurno *via* Madeira, St. Vincent, Ascension and St. Helena to the Cape, and thence *via* Mauritius, Rodriguez and Cocos to Western Australia, linking up by a cable from Cocos to the Dutch East Indies with the other route. This is now the Company's main route to South Africa and Australasia.

The Cable Companies afford an instance of a controlled undertaking. The British Government has no legal monopoly of telegraph communication with other countries, in the same way that it has a monopoly of internal telegraphy. But the foreshore belongs to the Crown, and before a cable can be landed the consent of the Government must be obtained. This necessity affords the Government an opportunity of imposing such conditions as it pleases upon the undertaking. The traditional policy of Great Britain has been free trade in cables, and the conditions which it has imposed have always been light. For some years past, however, the Government has been inclined to favour comparatively short licences, in order to give it an opportunity of reviewing the conditions at fairly frequent intervals. The usual conditions imposed in recent years include half rates for Government telegrams; a most favoured national clause, which ensures that the British public shall enjoy rates at least as favourable as those in force elsewhere; general observance of the conditions of the International Telegraph Convention, except in the case of Atlantic Companies, where this condition has not yet been imposed owing to the United States and Canada not being members of the International Telegraph Union; and latterly a clause providing for control of the licensee's rates of charge through the medium of the Railway and Canal Commission. This clause has never yet been put into operation, because there has not yet been any serious difference between the Government and the Cable Companies as to the reasonableness of their charges. But it might conceivably be of value if the Companies should ever forget their public duties in this respect.

Talking of charges, it may be interesting to give particulars of some of the earlier charges as compared with those now in force.

To the Eastern Provinces and States of North America, the minimum rate was originally £10 for 20 words. In 1872, the rate was 4*s.* a word. In the eighties, when the Commercial Cable Company first entered the field, and began to compete *à outrance* with the existing Companies the rate was reduced to 6*d.* for some 18 months; but this rate was found to be unremunerative, and the group of Companies combined to make the rate 1*s.*, at which figure it has remained ever since.

The following are some specimens of the rates of the Eastern and Associated Companies:—

To Egypt	1870	...	30*s.*	0*d.* for 20 words
	1873	...	20*s.*	0*d.* for 10 words.
	1876	...	1*s.*	7*d.* per word.
	now	...	1*s.*	0*d.* „ „
„ India	1870	...	40*s.*	0*d.* for 10 words.
	1876	...	3*s.*	9*d.* per word.
	1903	...	2*s.*	6*d.* „ „
	1905	...	2*s.*	0*d.* „ „
	now	...	1*s.*	8*d.* „ „
„ Cape	1879	...	9*s.*	3*d.* „ „
	1895	...	5*s.*	0*d.* „ „
	1899	...	4*s.*	0*d.* „ „
	1902	...	3*s.*	0*d.* „ „
	1903	...	2*s.*	6*d.* „ „
	now	...	2*s.*	0*d.* „ „
„ Singapore ...	1871	...	100*s.*	0*d.* for 20 words.
	1876	...	6*s.*	3*d.* per word.
	1897	...	4*s.*	6*d.* „ „
	1902	...	3*s.*	6*d.* „ „
	now	...	2*s.*	10*d.* „ „
„ Australia (N.S.W.)	1872	...	191*s.*	0*d.* for 20 words.
	1876	...	10*s.*	8*d.* per word.
	1886	...	9*s.*	6*d.* „ „
	1891	...	4*s.*	2*d.* „ „
	1901	...	3*s.*	6*d.* „ „
	now	...	3*s.*	0*d.* „ „

The system of deferred telegrams at half-rates was introduced generally in 1912—the theory being that time which would otherwise be unoccupied on the cables during the less busy hours could thus be filled up. The Atlantic Companies went one better, and charged 3/8ths (4½*d.*) instead of half the ordinary rate for such messages, although they have recently increased the charge to one-half. The system has been an unqualified success from the point of view of the public, and the Companies have had no reason to complain, because, although they carry a large traffic at deferred rates, their full rate service still remains large. In 1913 the week-end service at quarter-rates, with a minimum usually of 20 words, was introduced, the object being to fill up the spare capacity of the cables during the week-end. It was discontinued during the war, except in the form of soldiers' messages, and has not yet been re-introduced save on the Imperial and Pacific route to Australasia. The fact is that, broadly speaking, the long-distance cables are now too congested to warrant the resumption of the week-end service, as the week-end hours are largely required for working off accumulations of deferred traffic. On the Pacific route the amount of week-end traffic is quite large. From Australia it amounts to nearly as much as all the rest of the traffic put together. In the opposite direction, curiously, the proportion is much smaller. Clearly the week-end service on this route fills a public want. Whether it is altogether satisfactory from the point of view of cable finance is another question.

To encourage the transmission of news between the various parts of the Empire, low press rates have been introduced—though these are not quite low enough to satisfy the demands of the Press. The following are examples:

Between the United Kingdom and Canada		3½*d.*
„ „ „ „	Egypt	3½*d.*
„ „ „ „	India	4*d.*
„ „ „ „	Cape	3½*d.*
„ „ „ „	Australasia ...	7½*d.*
„ Canada and Australasia		5*d.*
„ the Cape and Australasia		3*d.*

On the Imperial and Pacific routes a "deferred" press rate is in operation of 2½*d.* a word between the United Kingdom and Canada, 4½*d.* between the United Kingdom and Australasia, and 2½*d.* between Canada and Australasia.

The traffic generally increased enormously during the war, and became still larger immediately after the war, when it amounted to about two-and-a-half times as much as just before the war. No wonder, therefore, that heavy delays were experienced, especially as the Indo-European Company's land-line route to India through Germany, Russia and Persia was out of action, as well as the Great Northern Company's route to the Far East *via* Russia and Siberia—with the result that all traffic to and from the East was thrown on the Eastern Company's cables. The traffic has now somewhat decreased, as every expert thought it would, and with the opening of additional cables the state of things has much improved, though delays are still greater than one could desire. To remedy this, the Companies are contemplating the provision of a new line of cables from England to Singapore, at a cost of more than £3,000,000—a good indication that in their opinion cables are by no means played out.

I promised to refer in greater detail to the Imperial Cable, and this seems a suitable point at which to redeem the promise. I start by saying that when war broke out the Germans were in possession of an important system of cables in the Atlantic and Pacific Oceans. The former system only concerns us at the moment. Apart from two comparatively short cables between Emden and Brest and Vigo, they owned two cables which ran from Emden

Digitized by Google

to the Azores and thence to New York, thus affording direct communication between Germany and the United States—each roughly 4,000 miles long, and each having cost roughly £1,000,000. They also owned a cable which ran from Emden to Teneriffe, thence to Monrovia, and thence to Pernambuco, with a branch from Monrovia to the German Possessions of Togoland and the Cameroons. The main line gave them a direct route to South America. All these cables were cut near the Straits of Dover immediately on the outbreak of war. Some sections in the Channel were used quite early in the war for the purpose of providing additional lines to France, etc., but the main sections remained unused for some time. In 1916, the suggestion was made that they might be diverted at this end to Allied soil, and used for providing communication between the Allies and North and South America. At that time the United States were still neutral; and it was considered that if an attempt was made to work the North Atlantic cables to New York, neutrality might be infringed. As an alternative, therefore, it was decided to divert one of them to Halifax, and the other to the French island of St. Pierre, near Newfoundland, which was already connected by cable with New York. The *Colonia*, the largest British cable ship, which is owned by the Telegraph Construction and Maintenance Company, started on her mission late in 1916; but was held up for some time by fear of submarines and raiders, and it was not until early in 1917 that she reached the scene of operations, picked up one of the German cables at a depth of over 2,000 fathoms—over 2 miles—S.S.E. of Halifax, joined on to it a new section which she carried, and then proceeded to lay the new section to Halifax. When this work was finished, a further difficulty manifested itself. The tests showed that a fault existed in mid-ocean at a still greater depth. In such cases it had hitherto been the rule to locate the position of the fault from each end of the cable, but this was not possible in the present instance, as the cable had been cut some time before near the Azores and had not yet been joined up again. It was therefore decided to rely on the indications given by the test from Halifax alone, and it speaks volumes for the skill of the experts concerned that the ship was able to find the place where the fault existed without serious difficulty. To repair the fault, however, was another matter, and took much time, and it was not until July 17, 1917, that the working of the cable began. It was worked direct between London and Halifax, with relays at Penzance and Fayal. Those of us who were concerned with the work will never forget the early days of the service, for it was a novel event in Post Office history, and in certain respects even epoch making. Little was made known at the time, but the cable for several months rendered most useful service, carrying large quantities of Government and other traffic between England and Canada and Australasia—with those terrible casualty messages each several thousand words in length, which the operators never handled without grief and never without pride.

By the time that the Halifax cable was put into operation, America had entered the war, and the other North Atlantic cable was therefore not diverted from New York.

About the end of 1917 the cable became interrupted through some cause, probably quite natural, which was never precisely ascertained. Owing to the submarine peril, it could not be repaired until after the Armistice; but from the time of its repair, with one short interruption, it has continued to work with the greatest regularity and efficiency. It is regularly carrying a load of from 220,000 to 240,000 words a week, or about 11,000,000 words a year, to and from Canada, the West Indies, New Zealand and Australia, and is making a satisfactory profit. It carries a few messages to the United States. But that is not its primary purpose. As its name implies it is an Imperial cable, intended to strengthen the links which bind the Mother Country with the great Dominions Overseas, and we have not thought it desirable that such a cable should be used seriously to compete with the great United States Companies for traffic to and from the States. Nevertheless, the United States public do not suffer in their service with Europe generally owing to this feature of the Imperial Cable service, because the traffic with Canada and Australasia which it carries would otherwise have to go by the American Companies' cables, to the detriment of United States traffic.

As every one knows, the German cables were ceded by the Treaty of Versailles to the five Principal Allied and Associated Powers—Great Britain, the United States, France, Italy and Japan. Their precise allocation among these Powers was not settled at the time; and this allocation was one of the principal items on the Agenda of a Conference which was held at Washington last autumn, and at which I had the honour to be the senior British delegate. The United States delegates were inclined to agree that the ownership of the Halifax cable should be ours, more especially as they recognised that we were not getting more than our fair share of the cables. But they were also inclined to complain that by the present use of the cable they were deprived of the direct service with Germany which they formerly enjoyed. In order to meet their views we agreed provisionally to exchange the cable for an equally good one touching only on British territory, if such an exchange could be effected without cost to Great Britain, and there the matter remains for the present; for although the United States agreed provisionally to this arrangement they refused to make it definitive until the general question of the remaining cables, in which we are not directly concerned, has been settled. This question could not be settled while we were at Washington, and is still not entirely settled.

At all events, the Imperial cable, whether the ex-German cable *via* the Azores, or an equally good cable touching only on British territory, has come to stay. And as already explained we have provided a duplicate by purchasing the Direct United States Company's cable, which—although leased for the moment to the Western Union Company—can be taken over immediately if the Imperial Cable is interrupted, or if the traffic becomes too great for it.

My remarks to-night would be incomplete without a reference to Imperial Wireless Telegraphy. The Imperial Wireless scheme has had an unfortunate history—not because of any misdeeds on the part of the Post Office, but mainly because of the outbreak of war, and the consequent dislocation of the plans of the Government of the day. Without going into past history, I will attempt to describe the present position. The Post Office has just completed the station at Leafield, near Oxford, which was begun before the war, and which is designed for communication with a station near Cairo. The Cairo Station will be completed about the end of the year. Under the scheme of the Imperial Wireless Telegraphy Committee which reported in the summer of 1920, and whose report has been approved by the Government, these two stations will form the first link of a chain to East Africa and South Africa. A further pair of stations will be erected in England and Egypt, which will form the first link in a corresponding chain to India, Singapore and Hong Kong; and which, as we hope, will also be continued from Singapore to Australia and New Zealand. There will also be a further link between England and Canada. It was the view of the Committee to which I have referred—commonly called the Norman Committee, because it was presided over by Sir Henry Norman—that communication by comparatively short links of from 2,000 to 2,500 miles was preferable on all grounds, and especially on the grounds of reliability and cheapness, to communication by longer steps. It is mainly on this account that the report of the Committee has been criticised. The Prime Minister of Australia would have preferred more direct communication between Australia and England; and Mr. Robert Donald has been the chief representative here of the so-called "one-step" scheme to India, and the two-step scheme to Australia through a single intermediate station. I confess that I entered the Committee prejudiced in favour of the longer steps. But none of my colleagues favoured the idea, and the experts brought very strong arguments against it. The experts who are now planning the stations, in accordance with the recommendations of the Committee, have reconsidered the question, but are still in favour of the short step scheme, although they consider that with the short step scheme direct communication will be possible during an average of two hours daily between England and Australia, and communication by means of a single intermediate station for a much longer time. I find too that the best experts everywhere regard the Committee's recommendations as thoroughly sound, and I therefore acquiesce in and support them.

The only other point on which the Committee have been criticised is their proposal for Government ownership and working of the scheme. The success of private enterprise in the case of cables is pointed to, and it is said that private enterprise could provide the wireless chain more quickly and more efficiently than the Government. But, however this may be, the Government have decided that there are conclusive objections to handing over the scheme to private enterprise. The principal of these objections is that wireless telegraphy is in the nature of things monopolistic in character. The number of wave-lengths suitable for long-distance communication is very limited, and the wireless chain could not be duplicated in the present state of knowledge without the gravest risks of interference—such interference indeed as would probably render the working of the stations impossible. Hence we must contemplate limiting ourselves for the present to one set of stations only, serving the various parts of the Empire; and if there is to be one set of stations only—in other words a monopoly—it cannot be allowed to be a monopoly in the hands of a private company—it must be a monopoly in the hands of the State. These considerations obviously do not apply to cable communication, which is not by its nature a monopoly, seeing that cables do not interfere physically with one another.

The Norman Committee was careful to point out that no existing long-distance wireless service is entirely satisfactory from a commercial point of view. Owing to difficulties of reception arising from atmospheric disturbances, etc., the rate of working is slow compared to that of cables. In a recent answer given in the House of Commons, the Postmaster-General stated that—*e.g.*, the Bordeaux station in France and the Nauen station in Germany both of them communicating with the United States—is not more than some 14,000 words a day, or say 100,000 words a week, as compared with the load of from 220,000 to 240,000 words which is carried by the Imperial cable—and that cable is by no means filled to its full capacity. The experts who are now planning the Imperial stations are hoping to produce much more efficient stations than any which now exist, and this is necessary if wireless telegraphy is to compete successfully with cables, or at all events to carry traffic at materially lower rates. The capital cost of a pair of long-distance wireless stations is, or should be, considerably less than a corresponding cable; but the rate of depreciation, and the engineering cost of working are greater; and it has still to be proved that on the whole the annual expenses are very much less in the one case than in the other. Hence, if the possible load is also materially less, the supposed advantages of wireless in point of costs disappear.

But a wireless chain throughout the Empire we must have, if only for strategic reasons, and if only because other great Powers are rapidly building similar chains. And if we are to have a wireless chain at all, it is obviously for every one's interest that it should be a commercial success. This is what the experts who are designing the stations are aiming at. And I am able to assure you that as soon as their plans are complete—and I hope that will be next month—the scheme will be pressed forward by the Postmaster-General with the utmost speed, with the object of providing the Empire with a system of wireless communication, which, like its cable system, shall be the best in the world.

ACCURACY OF REGISTRATION.

ANSWERS TO SOME QUESTIONS RAISED BY SUBSCRIBERS.

(1) "*How are our calls registered?*"

"*What is the telephonist supposed to do?*"

The telephonist's instructions are these:—

(*a*) Calls within the unit fee area:—Depress "effective" register key once at the end of the call.

(*b*) Calls beyond the unit fee area:—Prepare ticket bearing calling subscriber's number and particulars of distant exchange; place cap over "effective" register key so that it cannot be depressed; and mark ticket "effective" when communication with distant subscriber has been established.

(*c*) "No charge" call:—Place cap over "effective" register key so that it cannot be depressed, directly it is known that the call is free of charge.

(*d*) Double lamp-clearing signal:—When both supervisory lamps (actuated by the subscribers' hanging up their receivers) glow at the end of a call, depress "effective" register key once (for unit fee call) see that ticket is marked "effective" (for call beyond unit fee area).

(*e*) Single lamp-clearing signal:—When only one supervisory lamp glows at the end of a call, enter circuit after waiting about ten seconds and say, "Have you finished?" If there is no answer repeat the expression, "Have you finished?" If neither subscriber replies, treat call as effective and disconnect.

(2) "*If a telephonist charges for a call which is ineffective, how could she correct the error?*"

If it comes to a telephonist's knowledge that a call she has registered as effective was in fact ineffective, her instructions are to act as follows:—

(*a*) Give the subscriber a free call of similar value if he is ready to take up such a call when the error is discovered.

If he is not ready to take up such a call:

(*b*) Cancel the charge either by preparing a "credit ticket" (for unit fee calls) or by the cancellation of the original ticket which has been wrongly marked as "effective" (in the case of calls beyond the unit fee area).

Credit tickets are assembled and their value is credited in the subscriber's fee account.

(3) "*But your register keys are operated by telephonists, and even the best telephonists make mistakes. What safeguards does your system provide against accidental overcharge?*"

The safeguards are these:—

(*a*) The universal rule, known to the youngest telephonist leaving the operating school, that no charge is to be made for a call known to be ineffective.

(*b*) The positive indication of the completion of conversation given by the glowing of the "supervisory lamps."

(*c*) The special procedure laid down for "delayed answer," "no reply," calls in which efforts to gain attention extending over 90 seconds and including complete change of connexions are made before the call is abandoned.

(*d*) The co-operation of the subscriber. When a call fails through difficulties disclosed after connexion with the distant number has been established, *e.g.*, cut off, wrong number, &c., the subscriber, by moving his receiver rest, can flash the telephonist into circuit and advise her of the difficulty, enabling her to give a fresh call free of charge.

(*e*) The system of "credit calls" referred to in Section 2.

(4) "*What is to prevent a telephonist deliberately overcharging a subscriber?*"

(*a*) The character of the staff, whose standards and traditions of service are as high as those of any body of workers in the Kingdom. This must always be the chief safeguard in any system operated by human agency.

(*b*) A pilot lamp glows on the switchboard face, and in full view of the supervisors and the telephonist's colleagues every time she depresses a register key. Charge tickets are also regularly checked.

(*c*) There is continuous supervision of the telephonists at the switchboard throughout all the hours of the day.

(*d*) The work of the telephonists is continually under observations at the Central Observation Office without the knowledge of the telephonists themselves. No telephonist, therefore, knows whether at a given moment her work is under observation.

(*e*) In addition to (*d*), similar service observations are frequently taken in the exchange in order that the local controlling officers may be aware of the points in regards to which improvement is needed.

(5) "*You require a subscriber to accept the Department's record as evidence of calls made. Since registration is effected by human agency, how can you claim infallibility?*"

Infallibility is not claimed. All telephone administration throughout the world, whether National, Municipal or private Companies, require acceptance of their records as one of the conditions of service. The reason for this is that there is no practical alternative.

(6) "*Then, if you do not claim infallibility, what reason is there for supposing that your record is more correct than a subscriber's?*"

The reasons are these:—

(*a*) The telephonist is carefully selected from a very large number of candidates for her possibilities in regard to accurate and speedy telephone work. Before appointment she has to pass educational and medical tests of fitness, undergoes a thorough course of training in an operating school before taking duty in an exchange, and steps are taken to ensure that she thoroughly understands the whole system of recording calls before she is put in charge of subscribers' circuits. For some time after entering the exchange, she is under special supervision, and her work is under close observation. In the case of a subscriber—except those large private branch exchange subscribers whose telephone work is entrusted to trained telephonists—the work of passing and receiving calls is frequently entrusted to persons others than the subscriber himself:—clerks, servants, &c., &c.—whose sense of responsibility, experience and sometimes reliability must in ordinary course be inferior to that of the specially-trained telephonist. Generally, therefore, in the case of disputed charges, it is a question between a specially chosen and trained expert, and a relatively inexperienced employee or servant of the subscriber.

(*b*) To each individual telephonist, the operation of recording, and where necessary of crediting, is one of the routine items incidental to the operation of every call. To the subscriber, the keeping of a complete record of calls is an additional operation, the necessity for which would only be fully apparent to the subscriber himself, and not to others who might be in a position to use his telephone. Not infrequently a subscriber's telephone may be used by individuals who would not desire their use of it to be known.

(*c*) Since acceptance of official records is a condition of service, it is the responsibility of the telephone administration to take all possible steps to ensure the accuracy of its records. It is not in strictness the responsibility of the subscriber; and though he personally may endeavour to take such steps in his own interests, it is frequently impossible for him to convey to all who may have access to his telephone anything approximating to his own sense of responsibility. This difficulty is likely to be felt particularly in the case of those London subscribers formerly on the Unlimited Service Rate, in the case of which it was formerly unnecessary from the subscriber's point of view to keep a record of calls.

(7) "*Why not take a brief written record of every call instead of a merely numerical record by the depression of a key? A subscriber would then be able to identify calls with which he is charged.*"

The taking of a written record of calls in this way would occupy very much more time than the depression of a register key. If a written record were taken of all calls, the number of calls which could be handled by a telephonist in a given time would be greatly reduced, and operating staff, Exchange equipment, and supervision costs would be greatly increased, necessitating further tariff increase if the system is to be operated on business lines. It must be remembered that the addition of even a few seconds to the operating time per call is a serious item in the aggregate, since during the year some 260 million effective calls are handled in London. Moreover, the fact that a call to a particular number is recorded against a subscriber would not necessarily convince him that it had been made from his telephone, with the result that questions as to the accuracy of charges would not be appreciably reduced.

Further, the system of recording calls in use in London has been investigated from time to time by representative business men; and has been approved by a committee of telephonist users in New York, and by a committee of the London Chamber of Commerce.

(8) "*Why not introduce an automatic register?*"

Because no automatic register has yet been devised which can distinguish between effective and ineffective calls. A register which recorded both effective and ineffective calls indiscriminately would be useless both from the point of view of the subscriber and of the Administration.

(9) "*Does not registration at the exchange of what were formerly unlimited rate calls, add greatly to operating expense?*"

No! For Administrative reasons and to maintain a high standard of accuracy, unlimited rate calls have always been registered at the Exchange. This practice made possible the simple and easily remembered operating rule that every effective call has to be registered.

(10) "*Is a subscriber, then, ever justified in challenging the accuracy of the account presented to him?*

Yes! Occasionally errors will occur in every business organisation; sometimes mistakes in reading the registers or in transferring the readings to the subscriber's account may arise; and a subscriber who keeps a careful record of calls made and is able to ensure that others using his telephone follow the same practice should call attention to any *large* discrepancy. The Department is always glad to investigate such cases.

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

BY F. ADDEY, B.Sc., M.I.E.E., FELLOW I.R.E.

Continued from page 4.

Reception of C.W.

So far we have dealt with the reception of spark signals. For receiving the signals emitted from a station using continuous waves rectifying detectors as used for spark signals are not suitable, as already explained. For this purpose it is necessary to impress on the receiving apparatus a continuous oscillation of slightly different frequency from that of the oscillations to be detected. These two series of oscillations will then inter-act to produce "beats," as shown in Fig. 7. This figure was supposed to represent a sectional view of two trains of waves differing slightly in wave-length. By considering, however, the horizontal lines to represent a scale of time, and the distance of the curves above or below these lines at any point to represent the strength of the current in one direction or the other at the particular instant corresponding to that point, exactly the same figure can be used to represent the currents flowing in a circuit in which two oscillations of slightly different frequencies are simultaneously set up.

The frequency of the beats will be equal to the difference between the frequencies of the separate oscillations. By suitable adjustment the frequency of the local oscillation impressed on the receiving apparatus can be made to differ by any desired amount from the frequency of the oscillations set up by the incoming signals. The frequency of the beats can thus be varied at will.

The oscillations of first increasing and then of decreasing amplitude which make up each beat are rectified, and the resulting pulse of direct current is passed through the telephones. A note corresponding to the beat frequency is thus produced.

The apparatus for the reception of spark signals using high-frequency amplification, as shown in Fig. 14, can with suitable adjustments be used also for the reception of continuous wave signals.

In connexion with the description of that apparatus it was explained that, with the proper conditions, continuous oscillations would be set up in the oscillatory circuits of the receiving apparatus. Suppose this state of affairs to have been brought about. The continuous oscillations in the circuit S_2C_2 will produce an alternating voltage of uniform amplitude across the plates of the condenser S_2, and owing to the rectifying effect of the crystal detector D a steady current will flow through the telephones.

Suppose now that continuous wave signals are received, of a frequency differing slightly from that of the oscillations already set up in C_2S_2. The signals will set up oscillations of their own frequency in the aerial, and these oscillations will be repeated across the transformers into the intermediate and final oscillatory circuits. It must be remembered that, although these circuits are tuned to the frequency of the locally generated oscillations, the frequency of the incoming signals will differ very little from that of the local oscillations and so the circuits will respond also to the signal oscillations.

The locally generated oscillations and the signal oscillations will therefore be impressed simultaneously on the circuit S_2C_2. Beats will be produced, the amplitude of the alternations of voltage across the plates of the condenser C_2 will rise and fall, and the current through the detector and telephones will pulsate in a similar manner. Thus a musical note will be produced, of a pitch corresponding to the frequency of the beats.

It is, however, possible to dispense with the use of a separate rectifying detector for receiving continuous wave signals. One method by which this can be done is shown in Fig. 18.

The valve filament is heated by the battery B_1, the current from which is controlled by the adjustable resistance R. The negative terminal of the high tension battery, B_2, is joined to the filament, while its positive terminal is joined, through the telephones, T, and the coil S_1, to the anode of the valve. The adjustable condenser C_1 is joined across the coil S_1 and forms with it an oscillatory circuit. The condenser C_2 is joined across the battery B_2 and the telephones.

The coil S_1 is one winding of a triple transformer, the other windings of which are P_1 and G. P_1 is joined in series with the aerial, the usual aerial tuning condenser C, and aerial tuning inductance L, being inserted. G has one end joined through the condenser C3 to the grid of the valve, while the other end is joined to the negative terminal of the battery B_1. The condenser C_3 is shunted by the high resistance R_3, the "grid leak."

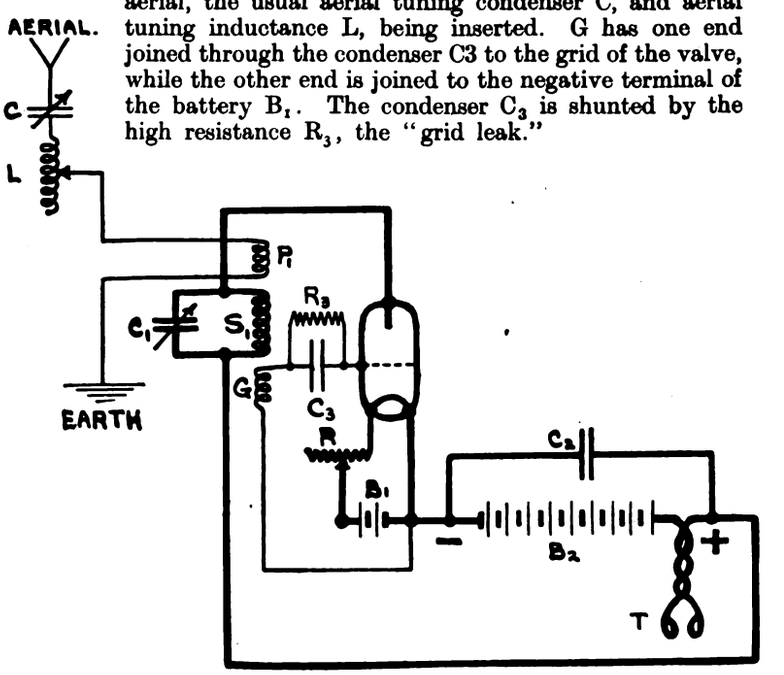

FIG. 18.

With this arrangement properly adjusted oscillations will be set up in the circuit C_1S_1.

Each swing of the alternating currents in S_1 sets up a voltage pulse in the coil G, which is impressed on the grid, and causes a corresponding change in the anode current, which flows through the coil S_1. These changes of current set up electro-motive forces in S_1, as already explained in connexion with the high-frequency amplifier, Fig. 14. The connexions are so arranged that the electro-motive forces in S_1 occur at just the right intervals to assist the oscillations already set up in the circuit C_1S_1. These oscillations consequently increase in magnitude till the resistance losses in the various parts of the circuit just balance the energy gains from the high-tension battery. When this state of affairs is reached the amplitude of the oscillations remains constant. The condenser C_2 provides an easy path for these oscillations across the battery B_2 and the telephones.

The oscillations will cause a negative charge to accumulate on the right-hand plate of the condenser C_2, as explained in connexion with grid rectification, and the mean value of the anode current will be reduced. Since the oscillations are steady, however, this reduced mean value will remain constant, and consequently no sound will be heard in the telephones.

Suppose now that continuous wave signals are received. The aerial circuit will be set into oscillation, and these oscillations will be impressed on the circuit C_1S_1 in which the locally generated oscillations are already occurring. If the natural frequency of this latter circuit, which determines the frequency of the local oscillations, be suitably adjusted the two series of oscillations will inter-act and produce beats. The amplitude of the alternating current which actually flows in the circuit C_1S_1 will vary similarly to the curve (*c*) in Fig. 7. The beats of alternating voltage set up in the coil G by the current alternations in S_1 are impressed on the grid, are rectified there and cause corresponding current pulsations in the anode circuit. Since the current in this circuit flows through the telephones a musical note, of the frequency of the beats, will therefore be heard. (*To be continued.*)

THE BAUDOT—XXVI.

By J. J. T.

Continued from page 3.

In the last article we dealt with the orientation, or phasing as we may call it, of the *corrected* station. The *point of repere* having been fixed at the corrected end of the line it is now time to examine the position of affairs at the *correcting* station B (Figs. LXIX and LXX) which we recall sends *out* the correcting currents to the *corrected* station A in order to actuate the synchronising coils CM. In the case of a *correcting* station the marking currents sent out by its *corrected* station should be received by the former exactly at the moment when the brushes pass over the segments connected to the respective electro-magnets of the receivers. Let the *corrected* station A (Fig. LXX) send out a marking current from any segment connected to one of its transmitting keys, D for example. This current after traversing the usual path from Ring 2 would pass out to line and should be received at B, while the distributor brush was passing over the corresponding receiving segment D^1 of Ring 2 at this station. Presume that this particular current is destined to actuate electro-magnet E^3, then the brushes at B should necessarily pass over S^3 of Ring 1 (the local ring) at exactly the same moment when those of Ring 2 at B are passing over segment D^1 (Fig. LXX).

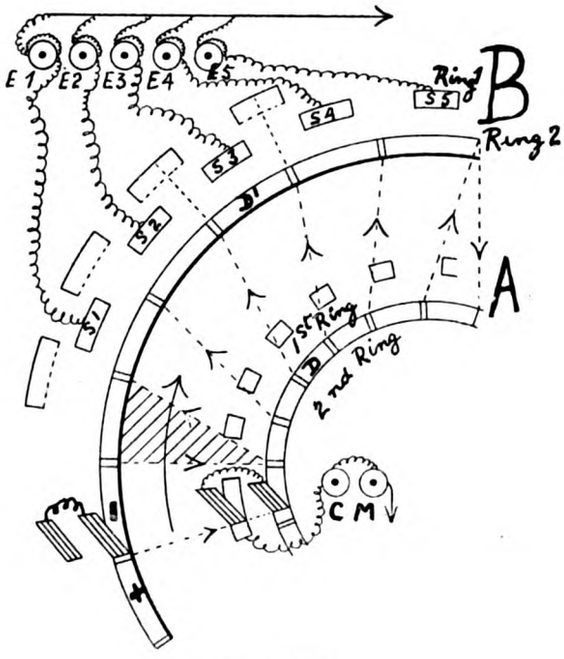

FIG. LXX.

Suppose, however, that the brush of Ring 2 were to pass over D^1 while the brush of Ring 1 was passing over S^2 then the electro-magnet E^2 would be actuated, *i.e.*, the "second" would be received instead of the "third" or to put it in another fashion, B would be receiving "in advance." If the reverse were to take place and the brush of Ring 2 were to pass over D^1 while that of Ring 1 was passing over S^4 then E^4 would be actuated and B would receive the "fourth" instead of the "third" or B's reception would be retarded. These effects could be remedied by moving the complete sector of Ring 1 of the distributor backward against the direction of the brushes in the first instance and forward in the same direction as the movement of the brushes in the last example. In the case of a double-plate Baudot, the entire receiving plate would be similarly moved until the middle position between the extremes was discovered. We will suppose that this position has been found, in which case B should continue to receive correctly.

Now it should be recognised that a *corrected* station is always in the more favourable position for receiving correctly than a *correcting* station.

It is, however, not quite so obvious that the position of the *repere* point of the *corrected* distributor has a deciding influence upon and is a governing factor in the reception of signals at the *correcting* end of a Baudot circuit. In this connexion students may need to be reminded of what actually takes place when the correcting pin is thrown out between the star-wheel of the correcting

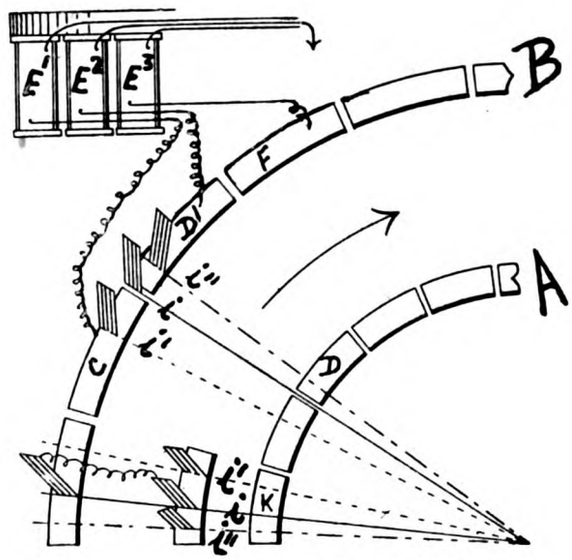

FIG. LXXI.

system of a Baudot distributor and the effect upon the rotating brushes of the epicyclic movement thereby set in motion (see Art. V, Vol. VI, No. 59, "we set the hands back," &c., &c.). With this refreshment of the memory the following paragraphs concerning the possible causes of a variation in the orientation of the *correcting* station should prove easier of comprehension. Suppose (Fig. LXXI) that the point of *repere* of the station A has been fixed at *i* on K and that A transmits a marking current from the segment D intended to actuate electro-magnet E^2 *via* segment D^1 at station B. If now by some means the *repere* point becomes shifted to i^1 on K, the angular distance between the *repere* point and D will no longer be the same, because the segment D will be nearer to the new *repere* point *i*. That is to say, station A transmits the marking current in question sooner than should be the case, since the segment D makes contact with the rotating brush sooner after the action of the correcting currents (*vide* Art. XXV).

Station B will therefore receive the marking current sent out from D somewhat earlier, receiving the same say at i^1 on C. The local current will consequently also act earlier and instead of actuating electro-magnet E^2 will energise electro-magnet E^1, the currents following being corresponding advanced in their arrival until the *repere* point is re-adjusted. If then the latter be shifted, let us say to i^{11} on K, this will mean that the angular distance between the original point *i* and D has by so much INCREASED and the current from D will be sent out later, reaching B at say i^{11} on D^1, even a portion being received on F, so that electro-magnet E^3 will be actuated as well as or instead of the intended E^2.

Figs. LXX and LXXI it should be noted are diagrammatic and do not of course represent actual connections.

(To be continued.)

CALENDAR OF COMING EVENTS.

Nov. 4. Society of Civil Servants. "Civil Service and Foreign Policy." Lord Eustace Percy, M.P.

„ 18. Society of Civil Servants. "Regionalism in Relation to Administrative Problems." Mr. G. D. H. Cole, Hon. Sec., Labour Research Department.

„ 21. Telegraph and Telephone Society. "Possibilities of Post Office Development." Mr. A. C. Winyard (U.P.W.).

Dec. 2. Society of Civil Servants. "London Government." Mr. Montagu H. Cox, LL.B.

RETIREMENT OF MR. STUBBS.

WE regret the delay in recording the retirement on July 31 last, of Mr. A. J. Stubbs, the senior Assistant Engineer-in-Chief of the Post Office. With the exception of a short period of 5 years, May 1902, to May 1907, during which he held the position of Superintending Engineer in the Metropolitan, North, District, Mr. Stubbs' service was spent entirely in the Engineer-in-Chief's Headquarters Office, and his retirement has severed the main link which, in the minds of many of us, remained in these later years to connect the present generation of Headquarters' engineers with the group of brilliant men who, after the transfer of the telegraphs to the State in 1870, laid the technical foundations which secured for the British Telegraph Service its long acknowledged reputation of the finest in the world. The wonderful page of State service history which unfolded itself during Mr. Stubbs' career was charmingly portrayed by himself in a paper, "Fifty Years of State Telegraphs," which he read before the Telegraph and Telephone Society of London in November 1920, and was reproduced in the JOURNAL during December and January last.

His contribution to the science and art of telegraphy cannot be expressed by a mere list of the many devices and items of apparatus which he has produced. His designs have been copied and adopted as standards all over the world, and scores of the beautiful drawings turned out with such facility in his earlier days are preserved in the Engineer-in-Chief's archives, but even more important is the fact that he was largely instrumental in shaping the governing tradition of British telegraph design which many others have, more or less unconsciously, adopted and followed.

A colleague who knew him well described him as "a gentleman and in every sense a man. He always joked; he never preached, but he could not help raising the tone of his company by his mere presence."

REVIEWS.

"Principles of Radio Communication." By J. H. Morecroft, Associate Professor of Electrical Engineering, Columbia University, assisted by A. Pinto, Assistant to Chief Electrical Engineer, New York Edison Company, and W. A. Curry, Instructor in Electrical Engineering, Columbia University. Published by Chapman & Hall, Ltd., London. X × 935 pp. Price 45s. net.

This is certainly the most important book on wireless telegraphy which has appeared recently. The developments which have taken place in this branch of Electrical Engineering during recent years have made obsolete much that appears in the older standard books, and in order to keep up-to-date, the student has to delve into the proceedings of the various Wireless Telegraph societies which exist in this and other countries. For many students this is difficult, if not impossible, and so the advent of a book in which, as far as possible, a complete up-to-date account of Wireless Telegraphy is given will be welcomed.

The book is divided into twelve chapters. The first one deals with the fundamental ideas and phenomena on which the whole of Wireless Telegraphy is built up and contains a full treatment of the laws of alternating currents, and a discussion of coupling and resonance effects.

The second chapter deals with resistance, inductance and capacity from the point of view of the high-frequency engineer.

In the third chapter is given a general view of radio communication and the difficulties which have to be overcome in practice.

The fourth chapter deals with the laws of oscillating circuits.

The fifth chapter deals with spark telegraphy, the sixth with thermionic valves, and the seventh with various systems of continuous wave telegraphy.

The eighth chapter is devoted to radio-telephony.

Then follow chapters on antennae and radiation, wave-meters and their use, and amplifiers.

The final chapter is on Radio Experiments and should prove of great use to the student who wishes to carry out practical work bearing on the theoretical matter discussed in the preceding portions of the book.

The book is very freely illustrated with curves and diagrams, which are extremely clearly reproduced. There are only a few photographs and these are not quite so well reproduced, but of course, for the serious student this is a very small drawback. The "all picture" type of text book is of little use to the man who really wants to *know*.

The standard of the book throughout is high, both as regards the method of treatment, and the way in which it is got up. Unfortunately the price is also high, but, considering present-day conditions in the book trade, it cannot be considered excessive.

The book is above the standard which the ordinary operator requires, but for anyone connected with the technical side of wireless telegraphy it should prove invaluable.

"The Post Annual." Edited by Geo. Middleton. Union of Post Office Workers. 76 pp. 2s.—This is a very enterprising and interesting production, well got-up and lavishly illustrated. It will, we imagine, appeal to a very large circle of readers, for it deals with all branches of the service. There are articles describing what the Engineering Dept. did in the war, the Air Mail Service, the Telephone from the operators' point of view, the Central Telegraph Office, what the Army Postal Service accomplished during the war, the Travelling Post Office, and London's largest sorting office. On the lighter side is an article on Early Days in the Savings Bank, written and illustrated by Will Owen, and there is a characteristic page of Mr. Heath Robinson's humorous drawings. Mrs. Patrick McGill has much that is interesting to say from the telephonists' point of view, but she repeats some of the charges she recently made in a daily paper, and we doubt if she serves their interests or flatters them by the statement that five years at the switchboard would make a wreck of the bonniest girl. It could easily be demonstrated that thousands of bonny girls have survived five years and longer service with their charms unimpaired. Such demonstration is not entirely within our province, but we think our long monthly lists of resignations on account of marriage are some sort of testimony. Portraits abound in the annual: the Postmaster and the Assistant Postmaster-General are there, and Secretaries, Officers in the "Signals," and Controllers are well represented. Mr. Sanderson finds himself in juxtaposition with Mr. Owen Nares, who comes in as judge of the Beauty Competition, a feature which we mention last, but not as the least.

RETIREMENT OF MR. SUTCLIFFE.

A CEREMONY of interest mainly to those connected with the Telephone industry, was performed on Oct. 3 at Leeds when a presentation was made to Mr. H. B. Sutcliffe, the late District Manager of the West Yorkshire Telephone District, and Mrs. Sutcliffe.

The presentation, which consisted of an elegant envelope card table, and a handsome sterling silver tea service of three pieces to Mr. Sutcliffe and a case of sterling silver teaspoons and tongs to Mrs. Sutcliffe, was made by Mr. T. Rodger (Traffic Superintendent) on behalf of the staff. Contributions towards the expense of the presentation were sent from all parts of the district, and the gathering (approximately 300) was representative of all grades. Among others present and taking part in the ceremony were to be noticed Mr. Hancock, Postmaster-Surveyor, Leeds. Mr. LeFevre, Postmaster of Bradford, Mr. Johnson, the Superintending Engineer of the North-Eastern District, and Mr. Lawrence, Postmaster, Dewsbury.

Reference was made with appreciation to the long telephone experience (37 years) of Mr. Sutcliffe and the loss that the service would suffer consequent on his retirement. Mr. Sutcliffe, on behalf of Mrs. Sutcliffe and himself suitably replied expressing his regret at this severance of his ties with the telephone world and pointing out that the way was now open for some younger man to take up the reins of office and push forward more strenuously towards the ideal of a perfect telephone service.

After the presentation ceremony followed refreshments, dancing, and a few musical items ably rendered by members of the staff. The occasion was the first meeting of the session of the West Yorkshire Telephone Discussion, Recreation and Social Circle. The membership extends over a wide area and is already about 200.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VIII. NOVEMBER, 1921. No. 80.

IMPERIAL COMMUNICATIONS.

WE recommend to all our readers the special study of Mr. Brown's inaugural address to the London Society. It was an admirable résumé of the history of Imperial communications, and it included a valuable vision of what these communications are to be in the future. It did full justice to all private enterprise as done in the past and as being done in the present, and it gave us a precise estimate of the value of the Government-owned cables and of the Government-owned wireless scheme. It left controversy aside except for one reference to the necessity for the State control of wireless. It has been said recently by some experts that there is only room for 270 long-distance wireless routes. That being the case it is quite clear that private enterprise could not be allowed to monopolise any considerable number of the possible routes. In this respect, as Mr. Brown pointed out, there is an essential difference between wireless and cables, and any question which might arise as to the Government ownership and control of cables must be decided by other considerations.

Naturally enough the audience was most interested in the future. There is always a danger when a new development arises of expecting rather too much from it, and Mr. Brown's judicious estimates are of especial value in checking undue expectations. Yet in the development of the Imperial Wireless Chain there will be opportunities for the British telegraph world which may affect the calling considerably. It will largely depend upon all that we do to qualify ourselves for this new development to what extent the Service gains by it. There is opportunity for doing something rather more than insisting upon claims. Strenuous work in mastering the various ramifications of wireless and the application of high-speed apparatus to wireless will be necessary, and this study will have to be carried on from different angles. There is not only the technical work of understanding how these machines will be adapted to the transit of signals by wireless, but there is a field for research in respect of the actual passage of traffic—the best method of obtaining repetitions, for example, the suitable batches of telegrams, the adaptation of ordinary working regulations to methods which have difficulties of their own, such as the interference of atmospherics and the like. It opens up a fascinating realm for study, and probably the two aspects of the study, the technical and the traffic, will need to be encouraged side by side.

All the old ideas of a fierce and angry rivalry between the cables and the wireless may be dismissed. They will be complementary. We are only at the beginning of the possibilities of closer welding of the Empire by means of these different methods of communication. It must be a little gratification to all of us every morning to see telegrams coming from Australia by the long route across the Pacific and across Canada and across the Atlantic within a few hours. It is a further gratification to notice how rarely commercial firms find it necessary to use the triple urgent tariff. To those of us who look beyond the sphere of commercial communications what is being done for the Press is a matter of pride. The canvassers for the Imperial Cable have their own droll stories to tell. They find the strangest misconceptions. Fortunately they are able to remove these misconceptions. The best feature of the whole enterprise is that the loss of a client who has once discovered the value of the service is practically unknown. Mr. Brown has put the enterprise on a high plane and it is up to us in our own particular vocation to be worthy of the high level upon which he has placed our calling in respect of the Imperial Communications.

RECORDING OF CALLS.

WE make no apology—nor do we think any is needed—for again referring in our columns in the form of a catechism to the substantial accuracy of the Post Office records of telephone calls. The Post Office has adopted a manually-operated system, while subscribers naturally would prefer an automatic record, such as that attached to gas, water, or electric light, and they fail to see why they cannot have it. They do not realise that the chief obstacle to a meter is the Post Office principle of charging only for effective calls. It would be a relatively simple matter to install a meter to record each and every call; but what the subscriber wants is one that will distinguish between successful and unsuccessful calls and between actual calls and signals, such as "flashing" for an operator. Such mechanism has yet to be invented, and it is therefore necessary for the work to be done by human agency.

But it is a mystery why a certain—luckily small—percentage of subscribers should assume that the human agent always has a bias against him, despite the constant assurance that the operator has nothing to gain by overcharging, and that the Post Office takes every possible precaution to ensure that both person and machine work accurately. Maybe some of the grumblers are those who are especially prone to doubt the business probity of other purveyors,

Digitized by Google

and who imagine that in all dairy, grocery or other businesses it is the habit to resort to various little tricks to increase profits, such as watering the milk, sanding the sugar, &c. Or they may only be of that type of individual who from temperamental or national characteristics considers that every man's hand is against him if not actually in his trouser pockets. Or again, he may be only a bully, or a sufferer from liver or gout, those hoary-headed excuses of ill-temper, and his household or employees may purposely conceal their use of the telephone so as to avoid another outburst. Or lastly, there is the element which disapprove of Government services, either on principle or from personal interests, and purposely endeavour to whittle away the reputation of Government services by constant innuendo.

Whatever may be urged to the contrary the fact remains that the Post Office records are fundamentally as sound as those of any other telephone administration; and, as the Post Office does not claim omniscience, it is always willing to investigate any reasonable complaint.

HIC ET UBIQUE.

THE *Automatic Telephone* informs us that out of 14 million telephones in the United States about one million are worked on the automatic principle. The conversion of the New York system of 900,000 telephones to automatic working will commence next winter, and it is estimated that the work will take 10 or 12 years to complete.

THE Hull Municipal Telephone system had a deficit of £13,279 on the year's working. It is hoped, however, by the end of the financial year ending in March 1923, that the Corporation will be in a position to build up a reserve. The new rates (33⅓ per cent. on the old ones) are now in full operation. The *Yorkshire Observer* says that the rate of telephonic development in Hull is the highest in the country, 10 inhabitants per telephone, but our readers will see from the paper which we publish that this is not the case. The ratio should be 1 to 26, whilst that for London is infinitely better.

IN our notice of Mr. Dawkes' retirement last month the printer unfortunately dropped the important word "never" in the fifteenth line. We think, however, that the intention of the paragraph was nevertheless clear. No one who knew Mr. Dawkes would imagine him unable to appreciate other points of view than his own.

THE *Yorkshire Telegraph and Star* has the following paragraph:

It is said that in American Post Offices, the work is accompanied with music, which moves from grave to gay, from lively to severe, in harmony with the needs of the workers. It is not generally known that there is nothing new in this, but that our own Post Office has long been working to music, and keeping strict time. The favourite measure is the "Dead March." The *telephone department* works staidly to the strain of "I hear you calling me," and in its livelier moods to "She only answered 'Ting-a-ling-a-ling' to all I had to say," or "Somewhere a voice is calling (number engaged)."

We can only rejoin with "Do not trust him, gentle maiden."

MUDALIYAR A. G. TILLEKERATNE, A.M.I.E.E., F.R.C.I., Superintendent of Telegraph and Telephone Traffic, Ceylon, who was on a visit to Great Britain on a holiday, combined business with pleasure, by investigating British methods of Postal, Telegraph, Telephone and Wireless work, and now returns to Ceylon through the Continent.

TELEGRAPHIC MEMORABILIA.

THE obvious drawbacks to a monthly periodical interested in so lively a pair of subjects as Telegraphy and Telephony have been particularly present with us these last two or three years. Staff changes, inventions, the kaledioscopic modifications of routes and the developments of wireless have sometimes followed with so great a degree of swiftness as to have become back dates and ancient history by the time it has been or *would* have been possible to publish the items in these pages. This seems to have been the case to an accentuated degree during the month that has just come to a close. Added to this factor must be placed a personal confession to the effect that a very lazy holiday in delightful country under ideal weather conditions must take a share of the blame for the belated tendency of one or two items at least. Having accepted the leniency of the general reader as a foregone conclusion, it would perhaps be accepted as an additional salve to conscience were the writer to vary the contents of these columns by giving a brief description of the *dolce far niente* spot where the holiday was spent. This, however, would probably raise prices for accommodation in the near future, so one must refrain except to give but a faint clue to this *terra incognita* by stating that it possessos a Post Office which refuses to be troubled with either telegraph or telephone, though the poles of the latter pass its door; the butcher calls twice per week, and the policeman apparently less frequently. It is eight miles to the nearest barber, about the same distance to the railway station, one or two of the inhabitants have never seen a railway train, and one or two villagers have *pannage* rights.

Not only will the death of Commodore Suenson be felt as a personal loss by the Great Northern Telegraph Company but the telegraph administrations throughout the world will doubtless recognise the demise of this noteworthy figure, which took place at Copenhagen on Sept. 21, as leaving a distinct gap in the line of submarine cable pioneers. The commodore was born in 1842 and in 1864 saw active naval service when in command of the Danish fleet. According to *The Electrical Review* it was in 1870, when the Great Northern China and Japan Extension Telegraph Co. was formed (afterwards amalgamated with the present Great Northern Telegraph Co.) that Suenson was sent out as General Manager to the Far East, "there to make the necessary arrangements for the landing and laying of the first telegraph cables between Hong Kong—Shanghai, Nagasaki and Vladivostok." The British Colonial Government gave every assistance for a suitable landing place for the first cable at Deep Water Bay and the right to connect it by a land-line to an office at Victoria, the main town of the island.

The connexion with Shanghai proved a different proposition. Here, strange to say, not only did he meet with the opposition of the natives who believed that the Chinese god "Fungshui" objected to any opposition in the way of projections into the air, but, "the European merchants of all nationalities which were established there were anything but delighted at the thought of getting the telegraph introduced in China, as this would put an end to, or at all events limit, the large speculation going on, and would also deprive the richer merchants of the advantage they had over their poorer *confreres* by dispatching their quick sailing steamers to Singapore for the latest news of the state of the European markets."

Suenson was not to be discouraged and eventually overcame the difficulties by changing the landing place of the cables to Gutzlaff and at Woosung where they have since remained. Commodore Suenson attended all the Telegraph Conferences and was perhaps one of the most potent influences in favour of the private telegraph companies' interests, not least of his qualifications was a fluent knowledge of Danish (his own tongue), English, French and German.

In terminating one of his particularly interesting papers, read before the Franklin Institute, on "Carrier Current Telephony and Telegraphy," to which the enterprise of our British contemporary, *Electricity*, has recently given very considerable prominence, Chas. A. Culver, Ph.D., of Toronto, remarks that while radio-telephony has a distinct and very important field in communication at sea, it obviously has serious limitations when employed for strictly business and personal purposes. While there is no means of communication which cannot be "tapped" (an opinion undoubtedly very strongly voiced by the late International Radio Conference.—ED.), yet from the nature of the system, direct guided-wave telephony by means of wires possesses the greatest element of secrecy of any telephonic means of communication. When, however, the high-frequency super-channel is used as a trunk line and connected at either or both ends with physical telephone circuits, the element of secrecy is again reduced to that of a physical circuit for the entire distance.

Another advantage of this guided-wave system is that communication may be maintained between two points when *the physical circuit is out of commission for ordinary telephone service. Both wires of the physical pair may be cut, the lines short-circuited and even one of the pair earthed without interrupting communication over the super-channel.* This has been repeatedly demonstrated and naturally means much in emergency service of all kinds."

The developments of this system which so far is only an economical one for long-distance circuits owing to the higher initial and maintenance costs of the physical circuit which is the basis of the system, these developments let it be repeated are sure tokens that wireless progress is not to be permitted to pass unchallenged. Already as the author states, "multiplex telegraphy by means of guided-waves is a commercial fact."

An interesting comment on the lack of secrecy of wireless telegraphy and telephony is the fact published in the *Electrical Review* of Sept. 9 announcing that "the private station of Messrs. Cunningham, Ltd., 169/171,

Digitized by Google

Edgware Road, is now in operation, and *anyone* is invited to inspect it and *listen to the signalling and telephony.*" The italics are the writers.

Nevertheless, wireless goes ahead and not the least successful of Government developments is the steady improvement in the working of the London (C.T.O.) and Cologne (*Haupt Telegraphen Amt.*) circuit, the daily performance of which is generally in the neighbourhood of 100 words per minute. The definition of the Wheatstone signals is amazingly clear and has frequently permitted reception by means of the Creed printer. The circuit would appear to be one upon which (*pace* atmospherics) trials with Baudot, Hughes, Murray, Siemens, or Western Electric would form a most interesting series of experiments and these certainly could not be *easily* tapped, at least by the general public.

It is not generally known, perhaps, that direction-findings by means of wireless for ships at sea are supplied by the British Admiralty at a cost of 5*s.* to any vessel which has lost or is uncertain of her bearings. The number of these demands during the month of August, according to *The Times*, was 160. As many as one thousand direction-found bearings were communicated during one of the preceding months. The demand, however, fell considerably below a couple of hundred when it ceased to be a free service!

The same authority gives an interesting little paragraph regarding the increase of the length of telephone lines in Czecho-Slovakia which it is reported has amounted to no less than 6,250 miles in two years. No further particulars are given so it is difficult to judge the real value of these statistics. Were they trunks or local circuits? Were they 200, 300 or 500 pair cables? Were they—— but no, one should not ask too many questions.

The projected submarine cable between Italy and South America, it is understood, will give direct communication between that country and Brazil, Uruguay and Argentina. The Italian landing place of the cable will be Fiumicino.

The following promotions at the C.T.O., consequent upon the retirement of Messrs. Bond, Fennings and C. Worthy, were unfortunately omitted from the last issue. It is hoped that these belated congratulations will lack nothing of sincerity by that fact. Each and all are tried and tested officers of a department which they have faithfully served, and the good wishes of all good men go along the road with them:—

Mr. D. M. Ford to be Assistant Controller.
Mr. F. W. Miles to be Superintendent, Section C.
Mr. W. H. Offord to be Superintendent, Section B.
Mr. T. M. Almond to be Superintendent, Section A.
Mr. D. Drenham to be Assistant Superintendent.
Mr. W. H. Marshall to be Assistant Superintendent.
Mr. E. W. Hewer to be Overseer.
Mr. W. S. Read to be Overseer.
Mr. M. Dunne to be Overseer.

Of the new Controller of the Edinburgh Telegraphs, Major A. A. Jayne, D.S.O., &c., what more can be said than has been said a hundred times regarding one of the most genial and understanding men the British telegraphist has ever experienced at home or abroad, in civil or military employ?

There have been times when we have not always seen eye to eye with the Engineering Department. "We differed 'twas our common pride," but it has rarely been the case that these differences between Traffic and Engineering methods and points of view have gone beyond the stage of good-humoured banter and friendly relationship, and this over a period measured by decades. If there be any man on the engineering side who has helped more than another throughout the whole of his service, now terminated unfortunately by ill-health, to help and foster a kindly relationship that man is George W. Connell, Assistant Engineer. "George," as he was known all over the C.T.O. building entered the Post Office Service as wireman in September 1883, and was promoted to Sub-Engineer in September 1899 and to Assistant Engineer July 1911. By sheer force of character, excellence of work, thorough knowledge of his job, he had climbed these few rungs of the ladder. There was not a man who knew the wiring of G.P.O. West and North better than he or the connexions of every type of apparatus, simplex or duplex, when as a lineman this was but a part of his routine to which was then added that of the maintenance of the local and trunk switch and test boards of the Trunk Test Room on the second floor, and the "Inter" switch on the floors above. He saw the C.T.O. pass from the general use of primary batteries with their hundreds of cells to that of the secondaries with all the changes which this revolution in power distribution involved at the time and grasped the new questions and the new methods and the new principles which they involved with that practical quickness which was the outstanding feature of the man. Isolated "shorts" or a few dozen such as those which resulted from the T.S. text-box outbreak or the Manchester conflagration were a joy, not at the destruction wrought, but at the sheer satisfaction resulting from clearing up a "lurid mess." If when as foreman a man under him was in fault no one could be more scathing than he, but no one could throw around that same man the protective shield against further castigation, and never man helped so many lame dogs over stiles as G. W. C. Help was given to one and all alike to high or low, and official position was small barrier to his candour. Not a few test clerks but would pay tribute to his unostentatious helpfulness, and his whole-hearted co-operation, and not a little to the blind eye which he did not fail to utilise when minor regulations prevented the traffic and engineering departments from "getting on with the job." Those who really *knew* George Connell will be the first to agree that the few lines spent on his eulogium only but indifferently appraise the value of the man. Into his retirement the kindest thoughts of old comrades and colleagues will follow during the many years of recuperated health and strength which it is hoped are yet in store for our old friend.

The London *Daily News* "chiel among us" has been taking careful notes of the undoubtedly harrassing experiences through which the ordinary S. C. & T. has to pass while on duty at a Post Office counter grappling "with the intricacies of Savings Bank and Money Order business, issuing licenses and selling stamps." Within three minutes, the following posers were put to the worried official behind the grille by a none too patient public, ravenous for information:—

> If I send £14 7*s.* 6½*d.* to Greece how many drachmai and lepta will my friend in Athens receive?
>
> Has the *Megama* sailed from Liverpool yet, and how much will it cost to "wireless" her?
>
> What is the postage to Monte Video on 2½ lbs. of "literature for the blind?"
>
> Say, mister, is this where I register for the unemployed money?

Eastern Engineering gives the very interesting information regarding telephone developments in China. A sum of approximately $1,000,000 it is expected will have been expended in improvements and extensions by the end of the present year. The submarine cable across the Yangtze connecting Nanking and Pukow and only containing one pair of wires is to be replaced by a cable containing thirteen times that number of lines. The materials for the exterior and interior work are being provided respectively by the Sino-Japanese Electric and Chinese-American companies.

On Oct 1 last was celebrated at Antwerp the 75th anniversary of the opening of the first telegraph line and office in Belgium. Administrative, Civil and Military authorities were all represented at the ceremony which included the solemn unveiling of a commemorative plaque bearing the names of those of the Antwerp staff who had fallen in the war. Mr. Kellaway, the British Postmaster-General, forwarded an aptly worded greeting on the occasion, of which the following is a copy:—

> Le Postmaster-General du Royaume uni envoye ses salutations à l'Administration et personnel du télégraphes et téléphones belges à l'occasion des fêtes pour la celebration du soixantedixcinquieme anniversaire de l'inauguration du premier ligne télégraphique en Belgique ainsi que la presentation de la plaque commémorative dediée a la mémoire des agents tombés pendant la guerre et il s'associe lui-même avec le personnel de toutes grades de l'Administration britannique dans une expression d'estime et égard à leur collègues belges.

The celebrations were continued at Brussels on the following day, M. Neujean paying high tribute to the telegraph staffs of the country.

An old friend and one-time telegraphist of the C.T.O., Mr. G. C. Mason, has been promoted to Superintendent of Wireless Telegraphy at the G.P.O. London. Those who remember the efficiency of G. C. M., either in T.S., T.S.F., or at the repeater offices, will hardly be surprised at his present advance in the new branch of the Service, and will be ready to tender him the sincerest congratulations. Mr. E. J. Ivison, late Assistant Staff Engineer, has been appointed Staff Engineer of the same branch.

The report of the *Compagnie Francaise des Cables Télégraphiques* notifies that the working of the Brest-Azores-New York cable which was entrusted to them by the French authorities, has proved very fruitful. The company has, it will possibly be recalled, already entered into agreements with the *Cie Générale de Télégraphie sans fil* for the joint working of wireless stations at Cayenne and in Northern Brazil, to which company they subscribed no less a sum than 12,000,000 francs towards the formation of the *Société Radio* of France which will operate on the American side of the Atlantic.

Fraternal sympathy is tendered to our Norwegian colleagues on the tragic death of M. Heftye, Director-General of the State Telegraphs, on the occasion of the appalling disaster at Skansen at the opening of the Dovre railway, and to our French friends by the equally tragic death of M. Carpentier in a motor accident.

The following extract from the *Electrical Review* gives perhaps one of the most curious instances of scientific development that as a result of political complexities one is likely to meet for some time. Events have resulted in an interesting electrical denouement in East Prussia, for as the new Polish "corridor" cuts off East Prussia from Pomerania a submarine cable, 170 km. long, has been laid in order to avoid any possibility of an interruption in communication between these two German possessions. This cable is to be used both for telephonic and telegraphic purposes, and contains six double-cores for the former and three single-cores for the latter. Single-core working for telegraph purposes was chosen partly on account of the limited space available, and partly to ensure due economy in copper. This choice was also largely influenced by the fact that it is now possible to reduce electrostatic and electro-magnetic induction effects, and so avoid trouble from disturbances of this character. The submarine portion of the cable passes under the Baltic from Leba to Tenkitten, and is connected at the home end with Hamburg, Stettin, and Berlin, and at the outer end with Königsberg. The telephone cores consist of copper wire 1.45 m. in diameter, and two copper strips, each 2.7 by 0.35 mm. The telegraphic cores consist of three copper wires, each 0.9 mm. in diameter. The telephonic core is wound with soft iron-wire 0.2 mm. in diameter in two layers and with three layers of paper, which bring the total diameter up to 4.4 mm. Each telegraphic core is wound with four thicknesses of paper, giving an overall external diameter per core of 5.2 mm. The cores themselves are covered with two

Digitized by Google

lead coverings, which are separated from one another by a layer of compound. The thickness of the lead is 1.9 mm., and an interesting point is that no tin has been used in its composition. The whole cable is covered with a lead sheath, which is protected against water pressure by two steel spirals. At intervals of 2 km. insulated plugs are built into the core for localising any damage that may occur. The average diameter of the submarine cable, including the jute protecting coverings, is 52 mm. Laboratory experiments, which were conducted on the cable before laying, indicated that if the lead were of sufficient thickness and were hardened by the addition of a little tin the risk of any breakdown from water pressure would be reduced to a minimum, but, even as it is, experience shows that the cable will be fully able to hold its own. It is, of course, the combination of telephone communication and telegraph communication on the same submarine cable that makes this installation interesting, and its operation under somewhat unusual conditions will therefore be watched with interest, especially now that increased telephone communication between this country and the Continent has become a vital necessity.

The Norddeutsche Seekabel Werke of Nordenham have provided nearly 3,000 kilometres of new submarine telegraph cable for the Dutch East Indies, which was delivered by the steamer *Flint* at Priok. The *Telegraaf*, the Dutch cable steamer, re-shipped cable sufficient to lay a new line between Singkel and Sibolga (Sumatra). Two others are to be laid, one between Java and Sumatra, and one from Makassar to Menado, and also from Makassar to Soerabaja.

Amongst the new patents "applied for" the following are noted :—

21,786 "Electric transmitters for automatic telegraphy." F. G. Creed and Creed & Co.

21,846 "Amplification and/or shaping of impulses in telegraphy." Eastern Telegraph Co., Ltd.

21,857 "Electric Telegraphy." Eastern Telegraph Co., Ltd.

J. J. T.

MR. LEE ON THE CIVIL SERVICE.

MR. JOHN LEE, Controller, Central Telegraph Office, delivered a lecture at the London School of Economics on Friday evening on "The Attitude of the Press to the Civil Service." Lord Riddell occupied the chair.

Mr. Lee said he thought the Civil Service had in many respects given some reason for criticism; there must be some reason for an excessive unpopularity. There was a genuine hostility against them on the part of the public at large, and it had been fed by certain writers who had chosen the fertile ground of public prejudice for their broadcast seed. The public still thought of them all as 10 a.m. to 4 p.m. men with long holidays. It supposed that incompetence did not count, and that salaries were irrespective of merit. But the attack, as an attack, did not come from the Press itself. In the main it came from a particular class who realised, quite shrewdly, that if the Civil Service was not curbed and discredited, it might become the machinery through which the consumer was safeguarded. This was a new class which had come into the possession of wealth—a class which was a problem to economists and the despair of the artistic world, and which was the greatest of all perils to social well-being. He watched on Sunday the stream of motors cars passing along a road near where he lived. It was a remarkable stream. Hundreds of well-equipped cars went by. What class owned them? Who could say? It was the problem of the hour. But it could certainly be said that they were not owned by the servants of the State. There was more public suspicion of Civil Servants' security, even when incompetent, than on any other aspect of their calling. He wished that he could plead that this was an unreasonable suspicion. Sooner or later the Civil Service of every grade would have to face that question. It was not the case that positive incompetence was as frequent in the Civil Service as in privately-owned administrations, but their machinery did not present to the public mind the means of eliminating the incompetent in such a way as to assure the public that those who remained were really competent.

A Government Department controlled the railways at a time when the central aim was that there should be fewer and fewer trains, and it came to be criticised simply because it succeeded, and the critics asked why there were fewer trains under Government management. The Civil Service had triumphed in those functions which belonged to it. Mr. Salter's book on Allied Shipping was a fine revelation of what a handful of men could do in administering what remained of the shipping world. The food supply was admittedly, on every hand, a vast success. If the world wished to do so, it could regard these precious achievements as translatable into dividends, but there was no dividend high enough for the translation. The Civil Service, founded on a basis which was the executive administration of a static condition, had been called upon to adapt itself to amazingly fluid conditions, to changes day in and day out, to a nervous and excited psychology, and to operations compared with which the operations even of the largest industry were puny and manageable. There was truth as well as error in the demand for a more business-like Civil Service. They needed to be watchful lest their methods became cumbersome and insufficiently responsive to the needs of the hour. Those of them who had had opportunities of studying industrial administration knew well that there was waste in distribution, waste in organisation, to which the Civil Service could offer no parallel. The "Popolo Romano" had remarked that "British merchants are certainly handicapped by the rate of exchange, but even more by their own methods of business." A London evening paper of the previous day had said, "If any British colliery manager got a job and attempted to run a German or American colliery for one day on his British methods, he would be dismissed within twenty-four hours." They were talking about the poor man as if he were a Civil Servant! But they were coming near the mark. England was reeking with proud and self-sufficient business incompetence. For the rest of this decade the worth of the Civil Service would be balanced against high taxation. Its mission must be to stamp itself with professional worth. It was worth while being called bureaucrats if it opened their eyes to the horror of being only bureaucrats.—(From *The Observer*.)

THE POPULATION OF THE LARGE CITIES ACCORDING TO THE CENSUS OF 1921 AND ITS RELATION TO THE NUMBER OF TELEPHONES.

WITH the introduction of the new rates in April 1921, the old telephone areas disappeared. The boundaries of these areas were curiously unequal and followed no fixed principle, with the result that whilst in most cases they included the suburbs of the town after which they were named, in others they included towns twenty miles away, which were, in fact, quite separate entities. The Chester area included Flint and Mold; the Exeter area, Exmouth, Budleigh Salterton and Sidmouth; the Chesterfield area, Bakewell and Matlock, and so on. It is necessary, however, for statistical purposes to fix some boundary for each urban telephone system other than the municipal boundary of the chief town. Salford, for example, is an integral part of the Manchester telephone system; Bootle, and one might add Birkenhead, of Liverpool; and Gateshead, of Newcastle. Instances might be multiplied; in fact, nearly all the large town-telephone-systems include more than one borough and its closely associated urban districts.

It would be scarcely more satisfactory to define Liverpool for telephone purposes as included in an arbitrary boundary comprising the boroughs of Liverpool, Birkenhead and Bootle only, or Newcastle as comprised in the boundaries of Newcastle and Gateshead. Telephonic development is indifferent to geographical boundaries, and a populous district not included in these limits may well be served by what is essentially a Liverpool (or Newcastle) exchange, as the case may be. It is therefore necessary to seek a more comprehensive boundary in order that the relation of telephonic development to population in a given town may be ascertained, and for this purpose a radial area of 5 miles from the chief exchange has been adopted for all provincial cities except Glasgow, Manchester, Birmingham and Liverpool (where a 7 miles radius applies), whilst in London the area within a 10 mile radius from Oxford Circus has been taken to represent the telephone boundary of the Metropolis. These areas are, of course, the limits within which a local call can be obtained for 1½*d.* under the new rates from the central parts of the towns in question.

The following tables show the population of all radial areas with upwards of 100,000 inhabitants (with the exception of a few which largely overlap others), the number of telephones they contain, and the number of inhabitants per telephone. The number of telephones in 1911 and their ratio to population in the old area, corresponding as nearly as possible to the new radial area, is also shown. Only preliminary figures of the 1921 census are at present available, and hence the figures are only approximate. In an industrial area which is covered by boroughs and urban districts it has been possible to give a tolerable exact estimate of the population, but in the case of a town which only one or no other urban district adjoins, it has been necessary to add a rough estimate of the population of that part of the rural districts lying within the five mile radius. Such estimates, however, do not greatly affect the correctness of the ratio of telephones to inhabitants. The population of the town itself is usually so overwhelmingly greater than that of the outlying parts of the area, that there addition is insignificant. For instance, the population of Reading is 92,200.

Digitized by Google

10,000 has been allowed for the small surrounding places in Oxford and Berkshire, making an estimated total of 102,000. Probably the exact figures of population, if they could be ascertained, would lie between 100,000 and 105,000.

The chief objection to the adoption of radial areas as the standard telephone areas is that in many cases they must necessarily overlap. In the tables subjoined Birmingham and Wolverhampton overlap slightly, as do several of the Lancashire areas, and Newcastle and South Shields. In these cases both the population and telephones in the places overlapping had been added to the total for both areas. Oldham and Stockport have been included in the Manchester area although they were both formerly the centres of separate areas, and Tynemouth in South Shields, and so on. Some difficulty was experienced in dealing with the Birmingham district, where the areas contained within a 5 mile radius of Birmingham, Walsall, Dudley and Wolverhampton overlapped to such a degree that many places were included in no less than three of them, and for this reason Walsall and Dudley have been omitted altogether from the following list. Out of 340,000 people within 5 miles of Walsall, only 96,000 were proper to that town, and out of 378,000 within 5 miles of Dudley only 56,000 were actually in the borough of Dudley. No census of Ireland was taken in 1921 and consequently the rough estimates for Belfast and Dublin are based on the 1911 census.

All cities and boroughs with upwards of 100,000 inhabitants appear in the following table.

Croydon, West Ham, East Ham, Leyton, Walthamstow, Tottenham and Willesden are included with London.

Salford, Stockport and Oldham with Manchester.

Birkenhead with Liverpool.

Gateshead with Newcastle.

Rhondda which is not a town, but an urban district consisting of several populous mining villages has not been included.

	Corporation System (Specified Area).				
Hull	13,209	327.5	24.8	12,082	26

The comparison of the radial areas with the old defined telephone areas is necessarily inexact. In most cases the old areas were of greater extent than the new ones, but the relative positions of the areas on the list is much the same in 1921 as in 1911. London now takes first place, Cardiff the second, and Edinburgh the third, these positions being formerly held by Glasgow, Brighton and London respectively. The Hull system (now the property of the Corporation) actually holds the second place in point of telephonic development, while in 1911 it was first on the list. Portsmouth and Brighton are the only places showing actual retrogression in number, due to the gradual cessation of duplicate telephones after the acquisition of the competitive Corporation systems, the slight decline at Bolton being due to the difference in the size of the old and new areas. London (with a smaller area than in 1911) has increased from 211,341 to 330,002, and Manchester with a larger area than formerly from 25,897 to 46,313. Dublin shows the greatest percentage increase, rising from 6,951 to 11,213. Newcastle and Bristol also show very substantial increases.

The inclusion of large suburban areas in the telephonic boundaries of towns, although affecting favourably the gross number of telephones in the area has almost always an unfavourable effect on the ratio of telephones to inhabitants. The following list has been prepared to show the number of telephones within the "county" or municipal boundaries of the 20 best developed towns. Places with less than 1,000 telephones have not been included :—

	No. Telephones	Population (1000's)	Inhabitants per telephone
London	286,177	4,483	15.7
Harrogate	1,752	38.9	22
Guildford	1,085	24.9	22.9
Chester	1,738	40.7	23.5
Bournemouth	3,560	91	23.3
Cardiff	8,300	200	24
Aldershot	1,203	28.7	24
Tunbridge Wells	1,481	35.5	24
Glasgow	40,260	1,034	25
Edinburgh	16,531	420	26
Newcastle	10,585	274	26
Manchester and Salford ...	35,966	965	26.9
Liverpool	28,950	803	28
Southport	2,608	76.6	29.5
Eastbourne	2,097	62	29.6
Ashton-under-Lyne	1,462	43.3	29.6
Bradford	9,517	286	30
Brighton and Hove	6,265	189	30.1
Nottingham	8,672	262	30.3
Aberdeen	4,901	159	32

The ratio of inhabitants to telephones within the municipal boundaries of *Leeds* (12,268 telephones) is 37, of *Bristol* (9,982 telephones) 38, of *Birmingham* (23,487 telephones) 39, and of *Sheffield* (11,539 telephones) 42. The figure for the municipality of *Hull* would probably be between 20 and 25.

Out of 14 towns in Great Britain with upwards of a quarter of a million inhabitants 1 has a ratio of less than 16, 6 of less than 27, 9 of less than 31, while 4 more have between 32 and 42 inhabitants per telephone. *West Ham*, which is part of Greater London, has not been treated as a separate entity.

LONDON TELEPHONE SERVICE NOTES.

London Telephonists' Society.

THE thirteenth annual session of this Society was commenced on Wednesday, Oct. 5, with the reading of the Presidential Address by Mr. M. C. Pink, who chose the subject, "The Future Development of the Telephone Service." The address began with an estimate of the probable growth of the telephone system in and around London, based on forecasts up to fifteen years ahead. The expectation of growth is surprising to those whose daily toil is in places removed from development studies and the like. Mr. Pink went on to deal with improved facilities which were expected to take shape in the not too distant future and described the advantages which would be gained by the establishment of an automatic tandem exchange for the handling of traffic which is now routed over lending junctions. The new system of operating short distance trunk calls through the newly-opened Toll Exchange was described, and figures were given in illustration of the remarkable improvement which has been effected. There followed a description of the telephone repeater and its uses and a reference to the possibilities of wireless telephony. The address concluded with a view of international telephony so far as it concerns present and future inter-communication with the British Isles.

* * * *

By the time these notes are read the next meeting of the Society will have come and gone, but the debate on Tuesday, Nov. 1, between Messrs. H. G. Corner and Horace Dive on the subject of "Has the Telephone added to the sum of Human Happiness" will doubtless still be a lively topic of conversation amongst those who were present.

On Wednesday, Nov. 30, the Society's third meeting of the session will be held, when Miss A. C. West will lecture upon "The Voice and its Effect on the Telephone Service."

* * * *

It behoves those who intend entering the Annual Competitions to get busy soon. The closing date of the first series is Dec. 31, so there is not too much time left.

The London Telephone Service Swimming Association.

The London Telephone Service Swimming Association held its Second Annual Gala at the Great Smith Street Baths, Westminster, on Friday, Oct. 7, before a crowded audience, whose enthusiasm was maintained at fever heat throughout a long and varied programme. The attendance was probably a record for the baths, and two Press representatives reported in their respective papers that it was the best attended and organised gala they could remember for the past twenty or thirty years. Such priase is indeed a credit to all concerned and especially to Miss Temme of the Trunk Exchange the hard-working Secretary, and to Mr. E. A. Pounds who was, as always, indefatigable as M.C. The starting, timing and judging of the various events was in the capable hands of prominent members of the Southern Counties' Amateur Swimming Association and of the Amateur Diving Association. The noble army of stewards and whips worked with a will and everything went with a swing.

The principal events resulted as follows:—

LONDON TELEPHONE SERVICE CHAMPIONSHIP (88 yards). (Gold Medal presented by Mrs. G. F. Preston).

First.—Miss Williams (R.E.) in 1 minute 25 seconds.
Second.—Miss Phipps (R.E.).
Third.—Miss Amos (VI.).

A splendidly contested race, won by five yards in very good time: 17 competitors started.

THE POUNDS CHALLENGE CUP. Team Race. (176 yards).

First—Gerrard (Misses H. Davis, Wilson, Burt and Robbon).
Second.—Regent (Misses Williams, Amos, Cole and Phipps).
Third.—Victoria (Misses Fern, Amos, Staig and Johnston).

Gerrard, who were the holders of this coveted trophy, succeeded in retaining it only after stalling off a serious challenge from Regent. The time of 2 minutes 44 seconds is very creditable. Twelve teams in all entered for the event.

SUPERVISORS' HANDICAP (44 yards).

First.—Miss Hare (VI.) 21 seconds start.
Second.—Miss Spalding (R.E.) 20 seconds start.
Third.—Miss Todd (MA.) 5 seconds start.

There were 17 entrants so that three heats had to be decided before the final trial. The racing was very keen and close throughout.

INTER-SECTION AND DISTRICT TRAFFIC OFFICE TEAM RACE (176 yards).

First.—Service Section (Messrs. Prossor, North, Beck and Pettigrew).
Second.—North-West District (Messrs. Dobson, Higham, Reece and Mason).
Third.—Equipment Section (Messrs. Webb, McCrimmon, Gregory and Hack).

Time, 2 minutes and 41⅘ seconds. This race introduced a new note, the previous gala being entirely feminine. It was a welcome change, for some of the mere men representatives of the Headquarter Traffic Sections and District Offices met for a trial of strength outside the field of dialectics. The first 44 yards was hotly contested by some of the veterans (in years only as it proved) and Mr. Prossor, the doyen of them all, succeeded in gaining a lead for the Service Section which they maintained to the end.

LEARNERS' RACE (one width).

First.—Miss Morris (C.).
Second.—Miss Hyne (HS.).
Third.—Miss Webb (M.).

The distance is not far when you know how, but how far off the opposite side of the bath seems when you have doubts about getting there. More pluck than was apparent was displayed in this event.

OPEN HANDICAP (44 yards).

First.—Miss Weedon (RE.) 33 seconds start.
Second.—Miss Johnston (VI.) 19 seconds start.
Third.—Miss Hawkins (PK.) 15 seconds start.

There were 56 entrants for this event and ten heats, and a semi-final had to be decided before the final. The racing was good throughout but the distance was rather too short to permit the backworkers being in at the deaths.

GRACEFUL SWIMMING COMPETITION.

First.—Miss H. Davis (G.) 71 points.
Second.—Miss Izzard (C.) 63½ points.
Third.—Miss Amos (R.E.) 63 points.

A very charming exhibition of swimming. Each competitor was required to swim breaststroke, backstroke and sidestroke.

LONDON TELEPHONE SERVICE DIVING CHAMPIONSHIP.
Gold Medal presented by J. F. Edmonds, Esq.

First.—Miss Williams (RE.) 26 points.
Second.—Miss Phipps (RE.) 25 points.
Third.—Miss H. Davis (G.) 24 points.

Another exhibition of charm and grace. How nearly equal were the exponents of the art of diving is reflected by the fact that the first three were separated from each other by one point.

LANTERN RACES.

First Race.—*First.*—Miss Jones (C.).
Second.—Miss Tuckett (CW.).
Second Race.—*First.*—Miss Williams (RE.).
Second.—Miss Hawkins (PK.).

Other items of interest included a Police League Water Polo Match and a Life-Saving Championship Match also between police teams. Special mention should be made of the exhibition of high and fancy diving by Messrs. D. H. Fairman, C. H. Bacon and A. S. Coombs, members of the Amateur Diving Association, whose efforts were most thrilling.

Mrs. Preston, who was accompanied by the Controller, very graciously presented the prizes. The staff were proud to have them share and indeed add to their enjoyment.

* * * *

By the way Gerrard were runners up this year in the competition for the London Business Houses' Team Race Competition, whilst Miss A. Davis of that exchange carried off the first prize for diving.

Langham Choral Society.

Since August the members of the "Langham" have been hard at work rehearsing for their opening concert of the season which takes place on the evening of Armistice Day, Nov. 11. The three works to be performed, Stanford's "At the Abbey Gate," Beethoven's Mass in C, and Elgar's "Banner of St. George" have been specially selected for the occasion, and it is hoped that the "Not Forgotten Association," in whose aid the concert is to be given, will benefit to a considerable extent. The soloists engaged are Caroline Hatchard, Margaret Balfour, Alfred Cracknell, Edward Dykes and Tom Kinniburgh.

Gerrard Exchange.

The patients at the "Queen's Hospital," Sidcup, were again entertained by the Gerrard staff on Saturday, Sept. 24. The entertainment was quite informal, and consisted of a sumptuous tea followed by a whist drive, dance and concert. The presence of the matron, officers and nurses lent an additional charm to the evening, which was pronounced by all to have been the success of the season.

City Exchange.

The City Exchange staff gave their first dance of the season at Stationers' Hall on Sept. 24. The Carnival spirit prevailed and a most enjoyable evening was spent. Further dances are being held at the Stationers' Hall on Dec. 3 and Feb. 25, and it is hoped they will be well attended by present and past members of the City Exchange staff. Miss Eastell of the City Exchange is the Hon. Secretary.

Trunk Exchange Bazaar.

The staff of the Trunk Exchange have organised a grand bazaar to be held on Friday afternoon and evening, Nov. 18. It is confidently expected that this their third venture in aid of the War Seals' Foundation and of St. Dunstan's will be at least a successful as those held previously which resulted in goodly sums being handed over to the charities named.

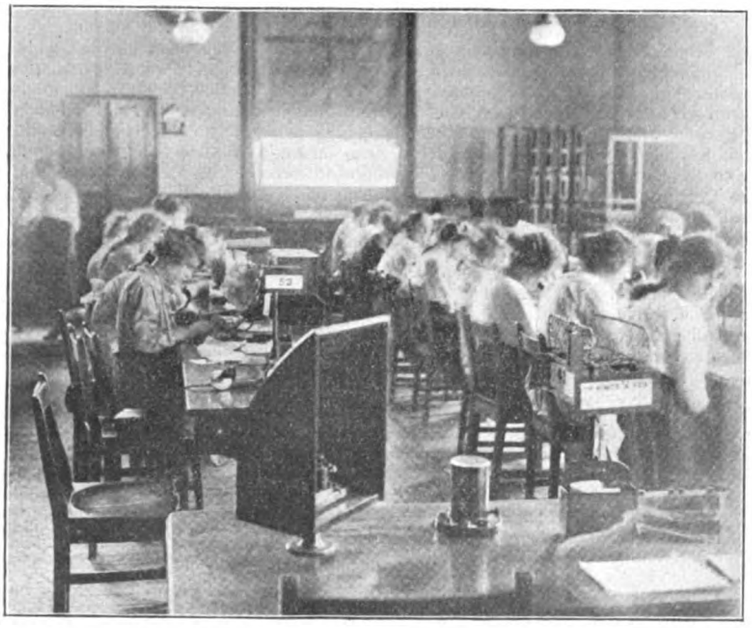
THE CENTRAL TELEGRAPH OFFICE SECTION, LONDON ENGINEERING DISTRICT.

G. F. GREENHAM AND P. G. HAY.

(*Continued from page* 15)



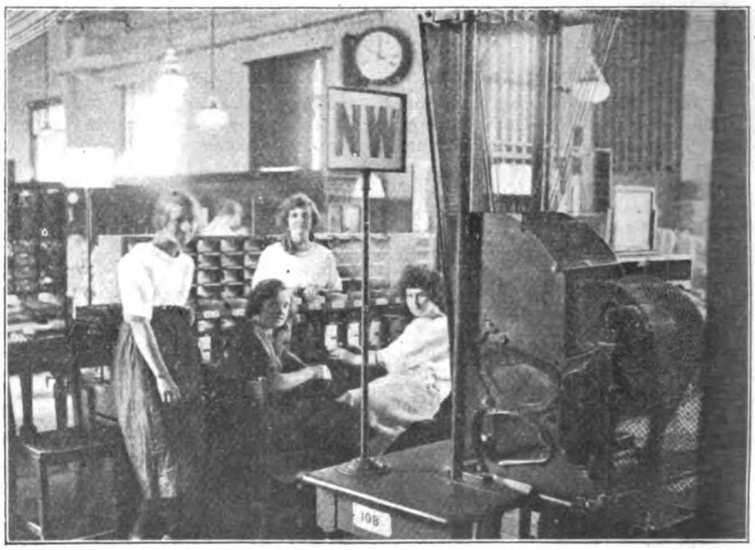
A very interesting feature in the basement is the Chronofer for the distribution of Greenwich Mean Time throughout the kingdom. The apparatus and electrically-driven clock forming this Chronofer combine to re-transmit the Greenwich time signal at 10 a.m. and 1 p.m. There is a Sub-Chronofer in the Metropolitan Gallery, and there are others situated in various provincial towns. A large number of provincial and metropolitan offices and subscribers receive one or both of these signals.

THE MECHANICS' WORKSHOP.

The lines over which the signal is transmitted to the various offices are of course in use for telegraph purposes normally, and the method by which the time signal is distributed is briefly as follows:—

At about two minutes before the "hour" (10 a.m. or 1 p.m.) a contact on the electrically-driven clock causes a current to energise a number of relays through the contacts of which the lines are connected to their respective instruments.

A CORNER OF THE METROPOLITAN GALLERY SHOWING THE CORD CARRIERS AND PNEUMATIC TUBES.



The relays, when thus energised, disconnect the lines from the apparatus and connect them to a second set of relays. From these latter relays the lines receive a positive current, which serves as a preliminary signal, but exactly at the "hour" the signal current from the Greenwich Observatory actuates the relays and reverses the currents on the various circuits. This reversal is the Greenwich Mean Time Signal. On the cessation of this signal current the line current is again reversed, and at two minutes past the "hour" the contact on the electric clock breaks and the lines are restored to their respective instruments.

Near to the test room is housed the desiccating plant consisting of a motor-driven pump—a container for the equalisation of pressure—and several cylinders containing calcium chloride for drying the air which is pumped into the air-spaced cables.

In the basement are housed the secondary cells for supplying current to the lines, local circuits, pneumatic tube signalling wires, bell circuits, small electric motors on machine telegraphs, the intercommunication switchboard, etc:

A very important adjunct to the telegraph apparatus pure and simple is the pneumatic tube service. For distribution of message forms from one point to another in the building an extensive system of house tubes is provided. The installation is worked upon a continuous vacuum system, in which there is no need for signalling apparatus, because the carriers are automatically ejected.

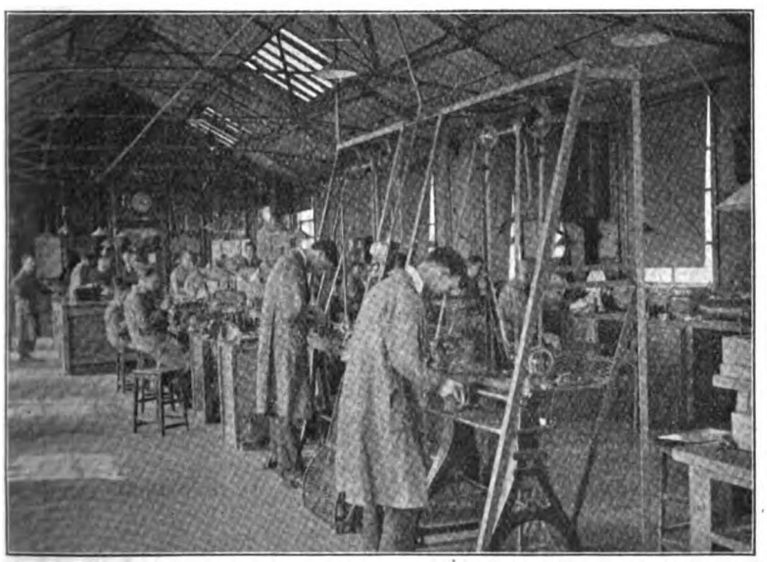
A carrier containing messages is inserted into the tube at the point of despatch through either a funnel or a door entrance, and is immediately caught by the vacuum and drawn to its destination, where a grid whilst allowing the "draught" of the vacuum to pass deflects the carrier through a flap and out of the tube into a receptacle beneath. The aggregate length of the house tubes in the Central Telegraph Office is four miles.

THE AUXILIARY PHONOGRAM ROOM.

In addition to the house tube system tubes are provided between the Central Telegraph Office and various large post offices and commercial offices in London, with which the traffic is very heavy. These street tubes result in considerable economy of space, time, staff, lines and apparatus. Among the offices thus served are the Western and West Central District Offices, Mount Pleasant, the House of Commons, the Baltic, and many branch offices and such commercial houses as the Eastern Telegraph Company, the Great Northern Telegraph Company, the Western Union Telegraph Company, the Commercial Cable Company and the Press Association. There are nearly fifty of these tubes, and their total length approximates to 50 miles. Inside buildings the tubes are usually of brass, but in the streets lengths of lead tubing are used, very carefully joined together so as to form a perfectly smooth passage for the message carriers, and protected from damage by being fitted into cast iron pipes. The power for driving the carriers through the tubes is in the form of either pressure, vacuum, or both, and is supplied by powerful pumping machinery driven by electrical motors. Approximately four 240 horse-power machines are available to work the system. With the street tubes wires are provided between the stations on the tubes, and fitted with signalling apparatus so that the tube attendants may signal the despatch and receipt of carriers, and in certain cases electro-mechanical devices are employed to regulate the feeding of a tube.

Another method of distributing messages within the building is by the use of mechanical conveyors in the form of band and cord carriers. The former consists of an endless band driven by a motor, which travels past the points concerned. A message is merely placed on the band and travels with it until withdrawn at its intended destination.

Digitized by Google



The cord carriers consist of groups of cords, seven in number, which travel in a somewhat similar manner and are actuated by rollers driven by small electric motors. The set of cords passes over rollers placed at various intervals and at the point of despatch the cords are splayed so that a message form can be interlaced with them. The cords grip the form and carry it to its point of delivery, where they are again splayed, releasing the form and allowing it to fall into its allotted space in the hollow of the framework forming the terminal of the carrier. A newer form of carrier for this purpose consists of a light rigid framework serving as a permanent way or guide rail, and a moving cord actuated by motor-driven rollers. A wire clip carried by the moving cord automatically grips the message at the point of despatch and a tripping device at the receiving station automatically effects the release of the message at its destination.

The C.T.O. Section is responsible for the maintenance of the street tubes in the London Engineering District, and for all construction and maintenance work in connexion with house tubes and telegraphic apparatus in the Centre and City Sections.

Work in connexion with extensive mechanical and electrical clock systems in various buildings used by the Post Office falls upon the C.T.O. Section. At the G.P.O. there are 15 master clocks controlling systems comprising some hundreds of dials.

To the manifold activities of which mention has already been made there has recently been added the upkeep of the automatic stamp-vending machines

G.P.O. West also houses the Phonogram Room containing the Phonogram concentration switch and its associated telephones for the distribution and receipt of telegrams, by telephone.

ANOTHER VIEW OF THE MECHANICS' WORKSHOP.

About 200 lines are connected to the Phonogram Concentrator and serve as outgoing and incoming junctions to telephone exchanges throughout London. About 150 telephone headsets are available for use with the concentrator, and when a subscriber wishes to make use of this service to originate a telegram his call is received upon one of the incoming lines on the concentrator and plugged through to a disengaged set. The message thus received is written down by the operator, at the set allocated, and circulated to the appropriate section of the galleries for transmission to its destination. A telegram received at the C.T.O. and marked for transmission by phonogram is circulated to the phonogram room and a disengaged operator is detailed to call through the message by means of one of the outgoing lines to the subscriber to whom it is addressed.

The C.T.O. engineers' activities on the telephone side are principally confined to the official switch, which as everyone knows is a Strowger type automatic installation.

The capacity of the installation is at present only 700 lines, but its upkeep has entailed an unusual amount of work, because it has been the installation where many experiments in connexion with the development of automatic telephony have been tried out.

The C.T.O. Section also contains workshops situated at Cornwallis Road, N., wherea staff is located for doing, for the whole district, general maintenance and repair work which is beyond the power of the local staffs to undertake. The workshops comprise a Smiths' a Painters' and a Joiners' Shop.

The bulk of the work is connected with the internal sections in the London Engineering District and concerns additions, alterations, and repairs to apparatus, frames, cable racks, etc., at the London Telephone Exchanges, when such work can be carried out economically by the department's staff. The work is done at Cornwallis Road or at the various exchanges as required.

The work performed for the external sections consists principally of special fittings for subways, manholes and footway joint boxes, such as cable bearers and cantilevers of exceptional shape or size. These all have to be cut, drilled, etc., and prepared in readiness for the external staff to fit in position. The assistance given to the External Sections also includes repairs when necessary to the ironwork of the trucks in the London District. A large amount of repair work is done in connexion with exchange and private branch exchange switchboards and in connexion with the very numerous telephone call office cabinets in use in the London District. The renovation or replacement of worn plug-shelves, keyboards, facing boards, is undertaken.

The number of telephone silence cabinets in use in the London District is very great and, in addition to slight alterations and repairs which can be carried out in situ, there is a continuous passage through the shops of cabinets undergoing repairs, alteration and renovation.

The cabinets thus rendered fit for re-issue include several very old types, which, in addition to dismantling, re-assembling and re-painting or varnishing, require such improvements as additional glass panels, etc., before they can be issued to meet outstanding demands.

To meet special requirements non-standard cabinets have sometimes to be provided, and the fitting of these and of standard types, and the grouping of nests of cabinets with such incidental work as the provision and fitting of attendants' booths form no small part of the work for which the staff at these shops is responsible.

The C.T.O. Section of the London District is considered by its own staff to be the most interesting in London.

LONDON ENGINEERING DISTRICT NOTES.

Progress.

ANOTHER relief exchange—Minories—was opened at 2 p.m. on Saturday, Sept. 24, with 795 junctions and 871 subscribers' lines. The subscribers connected were transferred from Avenue, London Wall and Bank. On Oct. 1 a further 574 subscribers' lines were transferred. The exchange is located at 98, Mansell Street, Minories, E.1, and is accommodated in a temporary building constructed for the purpose by the Office of Works. The ultimate capacity of the exchange is 2,000 lines and 40 "A" and 15 "B" positions have been provided. The installation is similar in all respects to Grosvenor. The work was carried out by the District staff and, in common with that of the other relief exchanges similarly constructed, the quality is of first-class order. The external work in connexion with the transfer was carried out under exceptionally difficult conditions owing to the congested nature of the plant in the manholes in which the necessary changes had to be made, and having regard to these circumstances it is a matter for congratulation that the transfer was effected without serious difficulty.

The work in connexion with yet another relief exchange—Hendon—will have been completed by the time these notes appear in print. In this case also the exchange is accommodated in a temporary building provided by the Office of Works. Relief will be given to Finchley and Kingsbury. The equipment consists of a suite of 7 positions (C.B. 9 multiple boards) which have been installed by the District staff. The capacity of the exchange is 500 lines.

Within the next few weeks the new exchange at Clerkenwell will, it is anticipated, be brought into commission. This will accommodate the lines at present working on the temporary Clerkenwell Exchange, which will ultimately serve as a relief to the Bishopsgate locality and become known as the temporary Bishopsgate Exchange.

The work of installing the plant for the new Stratford Exchange has been commenced, and the buildings for the new exchanges at Tottenham and Wembley are nearing completion.

Alterations and extensions have been completed at Hop, Finchley and New Cross Exchanges, and similar works are in progress at Willesden, East, Hampstead, North, Avenue and Lee Green. Extensions of the Ealing and Park Exchanges and the provision of a temporary exchange at Southall and another at Kilburn are in contemplation.

Private Branch Exchange work shows no sign of abatement. Many works are in hand. The wiring of the London County Council's offices at Westminster is proceeding and, as will be judged by those who are acquainted with the building, this work is of considerable magnitude.

Engineering Offices.

Accommodation for the Post Office Engineering Department in the London area is found by the Office of Works, and this fact sometimes leads to engineers finding themselves in unusual quarters. While one of the chief Inspectors in the Centre Internal Section is contentedly at work in a room previously part of a large workhouse, the Sectional Engineer and his office staff are at present located on the ground floor of a building formerly used as an Archbishop of Westminster's Palace. This fine building has been acquired on long lease and is located in 22, Carlisle Place, S.W. It bears outside a plaque announcing the fact:—

Cardinal Manning,
1808—1892,
lived here.

The building is shared with a section of the Ministry of Labour, dealing with the industrial training of ex-Service men of Middlesex. The Ministry of Health have a pathological laboratory located in the room previously used as the Private Chapel of the Archbishop. *Medical research of first importance*

Digitized by Google

is now being carried out on modern lines and the good work of combating disease by prevention proceeds apace.

The particular offices occupied by the Sectional Engineer were previously in occupation by the Board of Trade Profiteering Department, whose energies have now been stopped with a following increase in prices. It is not known whether this is a case of cause and effect. The most palatial of the rooms are occupied by the Royal Commission on the Oxford and Cambridge Universities, and any fine day, distinguished visitors such as Messrs. Asquith, Bonar Law and Balfour may be met upon the stairs. The premises are only in temporary occupation by the Sectional Engineer pending the release by the Admiralty of a building in Charing Cross Road which was purchased to house him and his staff.

The completion of the new Stratford Exchange building has led to the transfer of the North-East Internal Sectional Engineer and his office staff from Dalston to Stratford. Although Stratford may not be considered a desirable headquarters from some points of view, even compared with Dalston, yet it is generally agreed that the accommodation is very satisfactory.

Retirement of Mr. G. W. Connell.

Many readers will regret to learn that Mr. G. W. Connell, Assistant Engineer, C.T.O. Section, retired on Aug. 31 on account of ill-health.

The major portion of his official coreer which lasted for some 38 years was spent within the Central Telegraph Office, London, and probably no one had a more intimate knowledge of the plant in that vast building. During his official career Mr. Connell took active part in several of the more important events which go to make up the history of the telegraph system.

He had much to do with the extensive re-arrangements which were needed when the sixpenny tariff for telegrams was introduced. It is unfortunate that he was compelled to retire before its re-introduction. He supervised the replacement by secondary cells of the many thousands of primary cells originally installed. He was selected many years ago when a fire occurred at the Manchester Post Office, to conduct an emergency party sent from London, and to supervise their efforts in the restoration of communications. He has watched the gradual replacement of the simpler forms of telegraph apparatus by the more complex types so much in evidence to-day. His experience was not wholly confined to telegraphs, as he was chosen to supervise the construction of the Central Telephone Exchange.

Mr. Connell has now taken up residence in Cornwall and carries with him the best wishes of his colleagues, and the hope that the rest from work will enable him to enjoy his pension for many years to come.

North External Section Outing.

On Saturday, Sept. 17, the North External Section held their first Sports Meeting at Folly Farm, New Barnet.

The programme consisted of 25 events, which commenced at 2.30 p.m. and continued until 5.30 p.m., when an adjournment was made for tea, at which 250 members of the staff and their friends sat down. The programme was resumed and completed at 7.30 p.m.

A short concert followed, and presentation of prizes was made by Mr. C. E. Tattersall, Sectional Engineer, to over 80 winners. Expressions of gratitude were given to Messrs. F. Spicer, G. Stow and J. W. D. Billson, who had devoted much time and energy in making the outing such a great success.

The principal events and winners were as follows:—

100 *Yards Scratch Race.*—A. E. Godman, Dalston.
440 *Yards Scratch Race.*—G. Green, Finchley.
1 *mile Scratch Race.*—T. H. Bell, Tottenham.
1 *Mile Walk.*—J. S. S. Ricketts, Hornsey.
Inter-Section Team Race (6 runners).—Dalston.
100 *Yards Veterans'.*—F. Spicer, Hornsey.
High Jump.—J. L. Doubrowsky, Dalston.
Tug-of-War (8 men).—Finchley.
Tug-of-War (4 youths).—Hornsey.

Clerical Staff Changes.

During the past month a number of Established Clerical Officers have been transferred from the Provincial Districts to the London Engineering District.

These officers have come from all parts of the country—namely:—Scotland East, Scotland West, South Wales, North Wales, South Eastern, North Midland, South Midland, Eastern, Northern, &c.

A hearty welcome is offered to them and it is anticipated that when they have settled down they will have no cause to regret their transfer to London.

THE FIRM OF SIR CHARLES BRIGHT AND PARTNERS.

A PARTNERSHIP is announced between Sir Charles Bright, F.R.S.E., M.Inst.C.E., F.R.Ae.S., M.I.E.E., F.I.Radio.E., M.Inst.T.; Mr. A. Hugh Seabrook, M.I.Mech.E., M.I.E.E., Consulting Engineer (late Chief Engineer and General Manager to the St. Marylebone (London), and Electric Supply undertakings; Mr. A. J. Stubbs, M.Inst.C.E., M.I.E.E. (late Assistant Engineer-in-Chief, H.M. Post Office); and Lt.-Col. H. W. Woodall, C.I.E., M.Inst.C.E. (Director and Consulting Engineer of Gas and Water Companies); under the style of Sir Charles Bright & Partners, Consulting Engineers, with offices at 146, Bishopsgate, E.C.2.

The name of Bright is known throughout the world in connexion with telegraphy and electrical engineering generally. The original Sir Charles Bright, knighted at the age of 26, was associated with the laying of the first Atlantic Cable, while the present Sir Charles—the senior partner of the firm—has been similarly active for many years in land, submarine, and wireless telegraphy. Sir Charles Bright is also closely identified with aeronautics and the Air Service. Mr. Seabrook is a Consulting Engineer, and has been for over 25 years Engineer and Manager of various electric supply and light railway undertakings. Mr. Stubbs is the recently retired Assistant Engineer-in-Chief of the Post Office and a leading authority in telephony, as well as telegraphy. Colonel Woodall, trained as an electrical engineer, is a Director of and Consulting Engineer to Gas and Water Companies.

In addition to advising upon the installation and operation of telephones, telegraphs and wireless, the firm will advise upon gas, water, electricity and colliery engineering. In view of the heavy cost of fuel, economies have to be studied to-day that were negligible before the war. The firm will, therefore, specialise in fuel conservation in relation to the design and construction of power plants—steam, gas, electric, hydro-electric and oil—particular attention being devoted to the utilisation of low-grade fuels and carbonaceous materials, hitherto regarded as waste products.

PERSONALIA.

LONDON TELEPHONE SERVICE.

The following resignations of Telephonists' took place on account of marriage:—

Miss L. A. FINCH of Bexley Heath.	Miss A. B. IVERMEE of Putney.
Miss R. E. TUCK of New Cross.	Miss I. M. BARRY of Avenue.
Miss K.M.G. HOOKER of Bexley Heath.	Miss A. GOODWIN of Avenue.
Miss H. G. WAITE. of Victoria.	Miss F. M. ASHWOOD of Avenue.
Miss E. L. WARING of Victoria.	Miss H. G. JAMES of Avenue.
Miss J. A. MORGAN of Victoria.	Miss M. D. B. MCLEOD of Avenue.
Miss E. K. FRANCIS of Regent.	Miss D. A. BONE of Hammersmith.
Miss E. G. WILKINSON of Regent.	Miss D. M. WILLCOCKS of Holborn.
Miss G. V. R. FAITHFUL of Regent.	Miss A. O. BALDWIN of East.
Miss A. M. SHEPHARD of Regent.	Miss A. A. GENTRY of East.
Miss D. DOWDY of Museum.	Miss A. M. ATTWOOD of Kensington.
Miss L. H. SIDEY of Walthamstow.	Miss M. E. GARRETT of Sydenham.
Miss F. L. COWELL of Walthamstow.	Miss A. E. DAWSON of Avenue.
Miss M. G. MEIKLE of Walthamstow.	Miss L. E. W. RICHARDS of Avenue.
Miss E. A. POPE of Park.	Miss L. M. FARLIE of Greenwich.
Miss E. L. COURSE of Park.	Miss M. E. M. GOULD of North.

RETIREMENT OF MR. W. BROWN.

MR. WM. BROWN, J.P., District Manager, Dundee, who retired in May last, was presented by his colleagues and a few friends with a handsome gold watch, suitably inscribed, as a parting token of esteem and appreciation. Mr. Macfee, District Manager, Edinburgh, made the presentation by post, as Mr. Brown was enjoying a well-earned holiday touring the country. In his reply, the recipient thanked all his colleagues for such a tangible token of regard. He always experienced kindness and helpful advice from them, and the possession of the watch would be an ever present and pleasant reminder of by-gone days—if a reminder were necessary. The perusal of the list of his well-wishers recalled incidents of intercourse—orally and written—each bearing its little quota of fellow-feeling in the difficulties attached to the trying, and at the same time, interesting nature of the public service.

These recollections would live for ever.

RETIREMENT OF MR. J. FRASER.

IN the Imperial Hotel, Aberdeen, the staff of the Post Office Engineering Department, along with their friends, entertained Mr. James Fraser, A.M.I.E.E. late executive engineer, and presented him with a solid silver tea service. Mr. F. E. W. Cowie, who succeeds to the vacant post of executive engineer, presided over the gathering.

Mr. Harvey, postmaster, spoke highly of Mr. Fraser's services and abilities, and also of the good work he has done for the service, and Mr. Smith, assistant engineer; Mr. James Kerr, chief inspector; Mr. J. G. Dean, chief clerk; Mr. J. Finlay, lineman, spoke on behalf of their respective grades.

Mr. J. D. Taylor, after reading a letter from Sir William Noble, regretting his absence on account of pressing official duties elsewhere, made the presentation.

Mr. Fraser said the wrench was great in parting with his old colleagues. He thanked the staff for their loyal support, without which he could not have accomplished so successfully the work which he had had to perform. He referred to the growth of the section and also to the large amount of important work done since he came to Aberdeen.

THE LONDON TOLL EXCHANGE.

BY M. C. PINK.

IT is thought that readers of the JOURNAL may be interested to see the following notes which have been prepared in connexion with the London Toll Exchange.

The completion of the line arrangements for the exchange was delayed by the difficulties experienced by Contractors in laying ducts between the G.P.O. (South) and Norwich Street. The whole of the lines proper to the Toll system cannot be transferred until this duct work is completed, but as alternative routes could be found for the majority of the lines required at the outset, it was agreed with the Superintending Engineer that the system should be brought into complete operation so far as the London outgoing work was concerned, but that 78 of the incoming Toll lines should be left working in the G.P.O. (South) building until all the necessary cables would be completed.

On this basis the arrangements for the inauguration of the scheme proceeded. The exchanges included in the Toll area were of very diverse types and the circuit alterations involved were somewhat complex. It was most desirable that the alteration should be very closely watched and that there should be no failure so far as the public were concerned. It was accordingly arranged to transfer the Toll lines to the new exchange in groups. Incoming lines were transferred in three groups with a few days' interval between each, and the public were not officially informed of the proposed alteration of procedure so far as their outgoing calls were concerned until a considerable amount of incoming traffic had been actually passed through the exchange. When it was clear that arrangements were proceeding satisfactorily, every subscriber was notified by circular of the change in practice which was to come into effect on Sept. 17. During the week ending Sept. 17 the outgoing Toll lines were transferred to the new exchange in daily batches, the particulars of calls passed by the public for the transferred routes being passed on from the Trunk Exchange to the Toll Exchange.

In preparation for the establishment of the conditions of providing service on demand, a considerable number of new circuits had been provided. Some of these were provided owing to the necessity for the entire separation, under the new conditions, of outgoing and incoming lines. Previously some of the lines had been worked in both directions. Even after the provision of these lines it was anticipated, on the basis of the theoretical investigations made in connexion with the traffic arrangements, that a considerable proportion of the calls originated would probably fail to find a disengaged toll line at the moment of the receipt of the subscriber's demand. The equipment design provided for the probability of 25 per cent. of the received calls having to be reversed to the calling subscriber owing to slight delays in the maturation of calls.

In practice, however, this percentage has not been reached. Only about 5 per cent. of the calls originated throughout the whole day in London fail to find an available Toll line and have to be delayed for later completion. In the busiest hour of the day the pressure on the Toll routes is naturally greater and the percentage of booked calls rises on some days to slightly more than 14. The cases are spread over 58 of the 71 Toll routes, but on many routes the delays are only occasional and it would probably never prove economical to provide lines to secure *absolute* no delay on all routes.

The following 12 routes account for as many as 59 per cent. of the busy period (2 busiest morning hours) delays and it is of some interest to analyse the distribution of the cases:—

Route.	No. of calls delayed owing to Toll lines not being immediately available during busy period.				
	29 Sept.	4 Oct.	5 Oct.	6 Oct.	7 Oct.
Aylesbury	12	10	6	9	2
Bishops Stortford...	12	5	1	3	4
Boxmoor	11	23	4	5	3
Chesham	10	6	1	6	5
Dorking	16	15	22	15	23
Gravesend	25	6	9	24	11
Hertford	10	—	4	1	1
Leatherhead ...	4	13	19	11	30
Stanford-le-Hope ..	6	4	2	5	—
Uxbridge	8	5	2	4	3
Watford	1	18	16	15	7
Welwyn	12	8	2	1	10

It will be seen that the Leatherhead and Dorking routes account for a considerable proportion of the delays. It has not been possible at any time since the opening of the Toll exchange to give a satisfactory service on these routes. Additional lines are badly required. On some of the other routes the delay condition varies from day to day. In this connexion it will no doubt be appreciated that the toll routes now have to cater for the slightest fluctuation in the public demand. Much of the inequality in calling is straightened out under conditions such as previously obtained in the Trunk exchange where the calls were lined up in the order in which they were booked. It is perhaps not surprising that it was impossible to forecast exactly how the altered conditions would affect the ability to handle traffic absolutely on demand on every route. It will be seen, for example, that on the Gravesend route the booked calls varied between 25 on one morning, and 6 on another. On the Watford route, the variation was between 18 and 1, and on the Bishops Stortford route there was only one booked call on one day, whereas on another day the number rose to 12.

Digitized by Google

The following additional circuits are on order, and their provision will assist in reducing the number of booked calls :—

Route.	Outgoing Circuits. Existing.	Additional authorised.
Ascot	4	2
Bourne End	1	2
Beaconsfield	1	1
*Boxmoor	2	1
Bushey Heath	2	1
Broxbourne	1	1
Chertsey	1	1
Chorley Wood	1	1
Caterham	2	1
*Dorking	1	2
Dunstable...	1	1
Egham	2	1
*Gravesend...	5	2
Hatch End	1	1
Hoddesden	1	1
Horley	1	1
*Hertford	2	1
Kings Langley	1	1
Lingfield	1	1
*Leatherhead	3	1
Marlow	1	2
Maidenhead	7	4
Pinner	1	1
Potters Bar	1	1
Rickmansworth	2	1
Sunbury	2	1
Staines	4	2
*Welwyn	1	1
Westerham	1	1

* Routes specially requiring relief.

Further analyses are being made of the traffic on those of the specially pressed routes for which additional circuits are not already on order. Additional lines will then be ordered as required.

The following statement shows the amount of traffic handled daily up to Oct. 5 (inclusive) from the first full day's working on Sept. 19 :—

Date	No. of Revenue calls.	No. of Through Toll calls.	Miscins. Phonogram and Service Traffic and Ineffective calls.	Total calls passed outgoing on Toll lines.
Sept. 19 ...	3,902	236	547	4,685
„ 20 ...	4,151	274	546	4,971
„ 21 ...	4,162	278	545	4,985
„ 22 ...	4,252	258	564	5,074
„ 23 ...	4,293	297	534	5,124
„ 24 ...	3,168	222	581	3,971
„ 25 ...	930	57	126	1,113
„ 26 ...	4,172	321	528	5,021
„ 27 ...	4,189	280	537	5,006
„ 28 ...	4,290	289	510	5,089
„ 29 ...	4,326	300	561	5,187
„ 30 ...	4,682	307	580	5,569
Oct. 1 ...	3,413	221	533	4,167
„ 2 ...	918	73	94	1,085
„ 3 ...	4,243	300	546	5,089
„ 4 ...	4,092	264	443	4,799
„ 5 ...	4,890	332	562	5,784

Rather less than half the miscellaneous non-revenue traffic is in respect of telephoned telegram work passed by the Central Telegraph Office to Post Offices in the Toll area. The balance consists of calls which are cancelled by subscribers after receipt of a report either of delay, subscriber engaged, no reply from subscribers, or other miscellaneous reasons.

In order that the traffic might be properly distributed and reasonable loads might be handled, it was necessary, prior to the opening of the exchange, to give provisional valuations to all the different types of calls. Detailed traffic returns have been taken, but they have not yet been completely summarised. It will be necessary to take returns over an extended period before the provisional valuations can be confirmed or modified. The present indication is that the traffic has been slightly over-valued, and that it will be possible to handle the increased load which is to be expected during the coming months without any corresponding increase in the Toll staff.

The incoming traffic reaches about 6,000 calls per day on the circuits already working direct into the Toll exchange. The total will be considerably higher when the lines at present omitted from the scheme and retained temporarily in the G.P.O. (South) building are transferred to Toll.

It was expected that there would be some difficulty in breaking subscribers of the habit of asking for Trunks when they required places in the Toll area. During the first few days after the introduction of the Toll system, as many as 900 or 1,000 calls per day (nearly 200 in the busy hour) were still being passed to Trunks instead of Toll. The process of instructing callers is being steadily pursued. By the end of September, the numbers had fallen to about 650 in the day, and 120 in the busy hour. A later record showed a total of 476 for the day, and 108 in the busy hour. It will be seen that the improvement is definite although somewhat gradual.

So far as the accuracy of the records of Toll calls is concerned, there has been no evidence so far of any attempt on the part of a caller to evade payment by deliberately misstating his telephone number when passing a call. Occasional errors in repetition have been noticed, and in some cases subscribers who rent more than one line are quoting the number of a line other than that upon which the call is actually being passed. The latter type of case does not affect the revenue. Some inaccuracy in recording will be inevitable, but every possible step will be taken to keep the errors down to an absolute minimum.

The operating instructions compiled prior to the opening of the Toll Exchange provide evidence of the amount of detailed preparatory work that had to be carried out before the new scheme could be put in operation, and there is no doubt that the amount of thought and care expended on the scheme has been fully justified by the results.

The number of complaints of Toll service have been remarkably few. One written complaint spoke scathingly of the service on the Dorking route where the difficulties were admittedly great. Apart from this instance, however, the public appear to be very satisfied.

REVIEWS.

Die neuere Entwickelung der Funkentelegraphie, ein Siegeszug der Vakuumröhre. By Dr. Heinrich Wigge. Published by the "Ingenieur-Zeitung," Cöthen-Anhalt. 2nd edition. 71pp.

During the last few years the practice of wireless telegraphy has been completely revolutionised by the introduction and development of the thermionic valve. This remarkable piece of apparatus has already more or less completely replaced the older instruments and machines used for the production and detection of electromagnetic waves, while it has made easy other operations and methods of working which were quite impracticable before its introduction. The advance has been so great that the author of the small book under review is quite justified in calling it "a victory procession of vacuum tubes."

The book is divided into five chapters. In the first an account is given of the physical phenomena of which use is made in valves. Then follows a chapter on the different uses of valves in wireless telegraphy. This chapter is divided into six sections, in the first five of which the uses of the valve as oscillation generator, low frequency amplifier, detector, heterodyne receiver, and high-frequency amplifier respectively, are discussed, while the sixth section describes the method of joining up a complete station equipped with valves for both transmission and reception.

The third chapter deals with the manufacture of high-vacuum valves. In the following chapter the practical application of valves to stations on land, and in ships, air-craft and railway trains is discussed, together with the use of frame aerials and their application to direction finding, and of high speed receiving apparatus. The final chapter deals with the application of valves to wireless telephony.

The book concludes with a bibliography, in which is given, for each of the previous chapters, a list of references to sources of further information on the subjects dealt with in that chapter.

The book is written in a popular style, but the subject is nevertheless treated in a thoroughly comprehensive manner. In this second edition the subject matter has been revised up to the beginning of the present year. For anyone who wishes to obtain a good general view of what is certainly the most important section of present day wireless technology, we can strongly recommend it.

THE BAUDOT.—XXVII.

By J. J. T.

THERE is yet another case of faulty reception at the *correcting* station, the cause of which is to be found at the *corrected* end of the circuit. This fault may not in any way affect good reception at the latter, but it will throw out the reception of the former even after the point of *repere* has been definitely fixed. The fault in question may arise from incorrect relationship between the brush pairs of Rings I and IV, and II and V, at the *corrected* station, which is again a fault none too obvious at first sight. Let us suppose that the normal angular distance between the above-mentioned brushes has become decreased (the brush arm possibly shifted through not being tightly screwed in position, for example), and that this decrease has taken place in their travelling direction. Remembering that the point of *repere* is a local adjustment at the *corrected* station concerning currents received on Ring I which, nevertheless, affects the moment of transmission from the same distributor *via* Rings II and V out to line, then the result of this accidental closer relationship between the brush pairs mentioned at the *corrected* station would be that the transmitted currents from Ring II *via* V at the *corrected* station would reach the *correcting* station just a fraction too soon, and reception would be *in advance*. Naturally, if the distance between these two pairs of brushes had *increased* the currents sent out from Ring II would be received at the *correcting* station a fraction too late, *i.e.*, they would be retarded.

It may be safely stated that the causes likely to vary the orientation of the *correcting* station may all be traced to the above and/or to those mentioned in the preceding article.

In dealing with electrical signals received over telegraph wires, especially those signals which are conveyed from long distances by means of mixed lines—aerial, underground and submarine, there must of necessity be times when they reach the terminal office in a distorted condition. The rise and fall of the current as it reaches its destination is rarely perfectly defined. There is always more or less mutilation.

A and B (Fig. LXXII) will show more clearly what is meant. Here we see reproductions of photographs of actual telegraph signals as they arrived at the end of a long multiple core submarine cable after having been *repeated* at the distant end by an ordinary Fast Speed repeater. The originating signals first travelled over several hundred miles of mixed land-line. Photograph A shows a couple of these signals which are practically perfect, while photograph B gives ample evidence of some disturbing influence which has badly marred the rise and fall of two others which came through immediately afterwards.

Recognising these conditions, provision is made in the Baudot system for utilising the best portion of such signals, when they arrive, and as far as possible cutting away the mutilated portions. This is the function of the small segments which, as we know, are located on Ring I, which Ring it will also be recalled takes up the incoming marking currents from the tongue of the receiving relay *via* Ring IV, and passes them through the respective electro-magnets of the receiver. In single plate simplex sets such as that depicted at the commencement of these articles, Ring I is made in movable sectors each comprising a group of five small segments.

An important part of the adjustment of the *correcting* station is that of "taking the third." This adjustment is made by obtaining the continuous transmission of the third key from one of the keyboards (preferably the first) of the corrected station and adjusting its corresponding receiving sector as follows: Shift the sector slowly in one direction until the figure 3 (or the letter Y) disappears; mark the point; now reverse the movement until the "third" disappears in the opposite direction; mark this point also; now bring the sector back to a point exactly mid-way between. We shall now have adjusted our reception to the ideal position for reception, *i.e.*, the very centre of our wave peak. In duplex installations where the small segments of Ring I are not made in *movable* groups of five segements but in one complete ring, the same adjustment can be made by similarly shifting the entire plate.

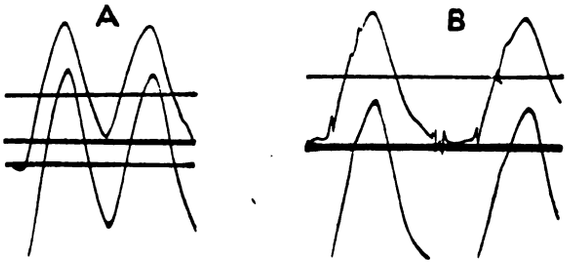

FIG. LXXII.

In this case each distributor face is fitted with a small indicator cut in equal degrees each side of a zero centre so that the exact position can the more readily be determined. These manoeuvres of the small segments therefore cut out all but the best of the arriving currents and as far as possible any variations, fast or slow, in the propogation values of the current.

Let us suppose Fig. LXXIII an experimental Baudot distributor C in which the segments of Ring I have *not* been shortened and therefore measure practically 1/24th of the circumference, instead of about 1/48th as represented by D. Let a signal now be received from the tongue of the relay on to Ring IV, destined to reach E^2

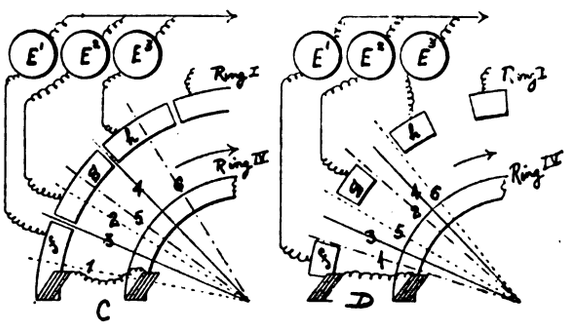

FIG. LXXIII.

by means of its corresponding segment. With so long a segment and with the most perfect of adjustments we could not be sure that the signal from Ring IV would fall absolutely in the limits of the arc 3—4, but might in fact be received in the arc 1—2, or in the opposite direction in the arc 5—6. Thus in the first case E^1, and in the second E^3 would probably be actuated as well as E^2.

Substituting small movable segments (see D) and adjusting so that the centre of our current wave, 3—4 received is received in the centre of the segment *q* (by taking the third as already explained), we shall ensure that the full height of the wave is passed into its destination, the electro-magnet E^2. This arrangement ensures that even with considerable variation of the actual moment of movement of the relay tongue the signal will be correctly received.

(To be continued.)

THE LONDON TELEPHONE DIRECTORY.

BY M. HILDA KNIGHTS (*London Telephone Service*).

To those of us who have been brought up in the London Telephone Service, there is but one *Directory*, although at times one hears faint far-off rumours of at least one other of lesser fame—Kelly!

The dictionary to which I turn in times of doubt, supplies the information that amongst other things a directory should be a guide, and I am going to attempt to show you some of the difficulties that face the Directory Section in its efforts to present a trustworthy guide to subscribers and also to give you a few items of general interest about the *Directory* and its compilation.

I shrink from the task of attempting to cater for every type of mind assembled here, but seeing that no paper is complete without at least a mention of statistics, those mathematically inclined may be interested in an estimate of the *Directory* as regards the extent of its circulation. The number of *Directories* which it was estimated would be required for the October 1920 issue, for instance, ran into more than 225,000 copies. If this does not convey to you any very clear idea of the extent of its circulation, you may be more impressed to learn that such an edition would consume paper to the weight of over 300 tons.

The *Directory* appears in a variety of bindings and in different qualities of paper. The edition which adorns *our* desks might be called the proletariat of its species, in that it altogether outnumbers its brethren, and has moreover a decidedly inferior dress, whose official name is "paper" covers. One of this class is supplied free of charge for each exchange line rented by a subscriber. When this copy is presented by the postman he holds firmly to the new one with one hand, until he is presented with the obsolete copy in the other hand—at least so a lady pathetically reported in conversation recently. It is extraordinary with what tenancious affection subscribers regard an old directory, but the Department maintains a hard and unsympathising attitude and insists on the relinquishment of the cherished book. When payment has been made for *Directories* the Department finds it difficult to recover those out of date, and these probably contribute to the number of fruitless calls made to the exchanges.

Additional copies of the *Directory* are supplied to subscribers without payment in certain circumstances, but only upon request. Copies are supplied free of charge for internal extensions only when the circuits are rented at the message rate, but an external extension invariably entitles a subscriber to another copy. Any member of the public may purchase a copy of the current issue of a *Directory* at a charge of half-a-crown, payable in advance, while an ordinary copy may be exchanged for one of a better class—at least so far as outward appearance is concerned—on payment of a shilling. This type of *Directory* boasts "stiff" covers, and has to endure more hardness than its friends in the corresponding walk of life. Yet another kind of *Directory* is that which is bound especially for use in Call Offices, and when one thinks of the rough usage to which these *Directories* are subjected, the need for strong bindings is obvious.

Some mention should also be made of the fact that a certain number of faulty copies reach subscribers. In the case of missing pages subscribers have been known to ask for those missing, in order that they may be inserted in the book. Needless to say, the Department attempts no such task; a new copy is sent with a letter of apology and an addressed envelope enclosed for the return of the faulty *Directory*.

Under the contract which has just terminated, the printing of the *Directory* was carried out by Messrs. McCorquodale, and in the editions printed by that firm there were roughly speaking three classes of type:—Firstly, the ordinary type in which the majority of names was printed; secondly, that which was known to us as "upper case" type, which was used for the first name of a group of similar names; thirdly, a larger type, for which special payment was made to the Department's advertising agents. The modest appearance of the upper case type used often to attract the notice of those subscribers who did not wish to flaunt their names, so to speak, in every eye, but who would write to say that an entry in that particular type would suit them nicely. Their accommodating manner was slightly perturbed when it was explained to them that this type was reserved for the first of each group of names, and they were still more perturbed when the larger type was offered, upon payment. Then they would hasten to assert that indeed no alteration whatever was required. Others there were who have shed their initials and asked for an entry showing the surname only in order to obtain the coveted type.

The style of printing employed in the *Directory* is constantly under revision, in order that each succeeding *Directory* may have more advantages and none of the disadvantages of its predecessors. To this end some alterations have been made in the present issue. These have been facilitated by the setting up of new type, consequent upon the Stationery Office taking over the printing and publication of the *Directory*. It will be seen that the name of the exchange is in bolder type than the remainder of the entry. This has the effect of concentrating attention on the exchange, which subscribers are requested to pass forward before the number. In addition the width of the book has been increased n order that it may not be so bulky to handle.

The daily press informed the public quite recently, that changes were to be made in the alphabetical order of names in this particular edition of the *Directory*. Unfortunately it assured the possessors of hyphenated and double names that such were no longer to be recognised and that the last surname of each name would determine the position in the *Directory*. For some time there has been a growing tendency to adopt one's mother's maiden name, or if that were not sufficiently imposing that of some family connexion. These names have consequently multiplied to such an extent that they now constitute an item to be reckoned with, and the London Telephone Service could hardly consider the possibility of ignoring them even if a daily paper had the temerity to suggest it. The immediate result of this statement in the Press was a letter from the owner of a hyphenated name with particular instructions as to which name was to be dispensed with. The actual fact is that they are no longer to be regarded as one continuous name and therefore follow closely upon the group of names to which their first name belongs. These names cause both their proud possessors and the Directory Section considerable trouble at times. I call to mind one subscriber who used regularly to request that in the next issue his name might be included under the letter S as none of his friends seemed to find him under T, and before the succeeding issue a further communication would be received (with no intimation that he had had any previous correspondence on the subject) to the same effect, only this time it was the S position that offended. One thinks of the unhappy man in connexion with those lines from Browning,

> "For whom each year we see
> "Breeds new beginnings, disappointments new."

I am glad to say he has at last found an anchor.

It is necessary to explain that a subscriber is entitled to an entry in the *Directory* free of charge for each circuit of which he is the renter, or in the case of auxiliary working lines, one insertion for each group of lines. The subscriber is supplied with a form which bears the heading, in what appears to the Department at any rate to be clear and straight-forward language: "Particulars for the *Telephone Directory*." There are one or two words of explanation added, to the effect that trading names are permitted, that description may not exceed three words, and that address should be as short as possible. After having spent a few years in the Directory Section one is forced to the conclusion that in addition to the three "R's," elementary education should include in its curriculum instruction regarding the use and abuse of printed forms. It is presumed that subscribers make some attempt to read what is required of them before they affix their signatures to such documents, but if some of the information supplied as description were imparted to the public it is at least questionable if the originator might not regard it as of doubtful benefit. The woman who *explained* herself as "married, with separate estate," or the more common "widow," would hardly wish to advertise the fact, at any rate not in a telephone directory: yet in the historic past, "widow" once appeared in an edition, and from the unfortunate woman's correspondence with the Department after the event, it would appear that the *Directory* had been mistaken for the *Matrimonial Times*.

After this small digression we return to the point at which the *Directory* form is used in the compilation of the *Directory*. To this end I must explain the preliminary steps. When a telephone agreement is signed by the subscriber, and after the necessary financial transactions, an Advice Note is prepared with particulars such as name, address, type of installation, exchange area, charges, &c. When the line has been connected and the Advice Note completed by the engineers, particulars are included on the Daily Report, which is, I believe, familiar to many of you, and the Advice Note is then started on its circulation in the office. At this point three cards of different colours are prepared for the Directory Section. These are known respectively as the numerical, street, and delivery cards: the two former are so named because the relative cards are filed in numerical, that is, exchange number order, and street order. The street card is always kept as an exact duplicate of the numerical card, so that in the absence of one card there is yet another upon which to rely. This particular index is the one to which Enquiry Exchanges most frequently turn in times of difficulty, and I believe I am right in saying that this is the only record of its kind in the Service. The ex-Directory record is not kept separately, as in the Enquiry Exchanges, but the numerical and street cards are stamped with this additional information. The delivery cards are also filed in numerical order and authorise the particular number of directories to be delivered for each line.

Upon the arrival of the Advice Note in the Directory Section, it is attached to the relative Directory form and cards which have preceded it, and the particulars are then compared and the insertion made on the special copies of the *Directory* which are prepared for the purpose and which are known as press copies. Amendments relating to changes of name or number, removal from one address to another, or recovery, are made directly from the Advice Notes.

Often the first indication that the Department has that a telephone is changing hands is the receipt of a letter asking for another name to be inserted in the *Directory*, and it frequently follows that this simple request involves the signing of a new contract.

At the time of going to press the staff employed on the Directory Section is more than doubled for about four to five weeks. During this period arrangements are made to include entries for all new lines and removals which are likely to be completed within six weeks of the publication of the *Directory*.

Digitized by Google

A temporary press copy is brought into use when the original is sent to the printers, and as this is merely an unaltered copy of the last issue of the *Directory*, the standard record in the branch consists of the information to be found on the cards in the numerical file. It is thus obvious how very important it is that these cards shall be an accurate record.

There is a feverish element in the eagerness with which a new *Directory* is welcomed in the section. It is difficult to find an altogether satisfactory reason for this, for with the pride that comes from looking on the work which our hands have made, there is also forced on our unhappy minds the truth of the adage—"Be sure your sins will find you out." There are a few subscribers who write in a calm and dignified manner and request us to be so good as to rectify a mistake in the next issue. But there are others—and with probably greater justification for annoyance—who are not so easily pacified, but one sympathises with them, for it is impossible wholly to make amends until the next issue. One might almost say that amateur detectives are developed in the Directory Section, for every error is traced to its origin, and at times this involves no small amount of investigation. There is much rejoicing and relief when a mistake can at any time be attributed to a printer's error. A special record is kept of all errors, and before the next *Directory* goes to press the proof is examined to guarantee that the same subscribers are not again penalised. I may, however, further suggest an unofficial reason for our anxiety to behold a new *Directory*. The branch which is artistic, at any rate collectively, likes to hazard opinions on the quality of the various productions of art which appear from time to time between the pages. A while ago a subscriber wrote to protest against the Department including in the *Directory* a picture which offended his moral sense and which he considered would lower the tone, not only of the publication, but of the young maidens employed in the Service. I must explain that the picture represented a lady just about to take a bath, her robe having slipped somewhat from her shoulders, which one presumed were beautiful because she had used such and such a soap—which was the subject of the advertisement. It was difficult to share the writer's concern, and it was not until it was discovered that he himself was a rival soap manufacturer that we appreciated that his motives were mixed.

That the Department maintains a fatherly interest in the morals of the community is however, evidenced by its refusal to do more than insert the fact that certain subscribers carry on business connected with the turf. Should such a subscriber ask for a large type entry, which is regarded by the Department as an advertisement, he is informed that his application cannot be entertained.

There are some subscribers who either consciously or unconsciously would embroil the Department in their small trade rivalries. To prevent this, special rules have been drawn up regarding the nature of entries permitted, and mention is not allowed of specific articles of commerce, also various instructions have been drawn up and amended from time to time relative to entries for Limited Companies. Generally speaking, a limited company must appear in its fully registered title, but there are exceptions for theatres, newspapers, hotels, &c. Old trading names also are occasionally allowed if they do not conflict with any other similar name.

Although the *Directory* is run on democratic lines, nevertheless a great interest is taken in the growth and rise of the peerage; and the newspapers are searched daily for notification of honours conferred. In contra-distinction to this, there are those who would make the book in effect a black list. Recently a suggestion was put forward that in order to save the compilation of a special list, a star should be placed against the names of subscribers on the King's National Roll. The Department was, however, unable to approve a discrimination of this nature in an official directory, where subscribers paid equally for whatever facilities they received in exchange.

In its treatment of the public services, one sees some sense of the responsibility of the State for the well-being of its citizens reflected in the attitude of the Department. Entries referring to Hospitals and Fire Brigades—those institutions which are associated with sudden calamities—are given special consideration. Not only are insertions made under their respective headings, but an additional entry in another alphabetical position is given free of charge.

As perhaps you realise, the Department not only provides a *Directory*, but attempts in the Preface and by instructional headlines on each page of the alphabetical list to educate the public in the art of using the telephone. The measure of success which attends these efforts is better known perhaps to our readers.

There is only time to mention in passing that in addition to the public *Directory*, there are also issued at intervals Government Directories containing the telephone number of all Government Departments, and official Directories in which are included all circuits connected with the General Post Office.

We are beginning to realise how closely allied is the work of the operating and clerical staffs, and some of us who are engaged on clerical work have had the privilege of visiting the exchanges with a view to gaining some insight into working conditions in order that we might be enabled to carry out our duties more efficiently.

May I hope that this paper may be a small contribution from the other side and make somewhat more intelligible the clerical work involved in the production of the *Directory*.

OUR FILM.

THE Gaumont Film Company have recently taken a complete film of the Central Telegraph Office to illustrate "The Romance of Postal Telegraphs." It is customary to be a little critical of the cinematograph. Many people are of the opinion that as a means of instruction and entertainment it is below the level of the demands of intelligent persons. On the other hand it would seem to be possible to use this science to explain to the public various industrial processes which serve them day by day but of the details of which they are unaware. There is something of the stage door attitude to life in most of us. We want to get behind the scenes and see how things are done. We are more interested in the shirt-sleeved stage carpenter than we are in the dramatic exponent. It would not be possible to show the public at large how telegraph work is done except by means of the cinematograph. The Gaumont Company is about to show to millions of the inhabitants of the world what the Central Telegraph Office is, how the work is done, and what are the details of the telegraph devices which strive to help industry and social life in the most efficient manner possible.

The film is a long one and will take upwards of an hour to run. It includes the transmission of telegrams by every known method. I am not sure of the proper technical language but in the case of some of the more interesting instruments the photographs have been taken "close up," showing the details of the machines and of the human operations. Long distance cables and wireless and multiplex routes to the provinces and to the continent were all placed under the microscopic eye of this revealer of secrets. One of the most interesting sections of the film deals with the transmission of Mr. Lloyd George's speech on the Vote of Censure. For over two hours the cameras were in place and the great "white-purple" lights were blazing. The operations were shown in detail from the acceptance of the reporters' slips to the transmission through the Intelligence Department, thence to the distribution and thence to the punching stage. Full replicas were obtained of the preliminary sheets and specimens were photographed of sheets as they would be printed by Creed and delivered at the distant offices. The operations of the Imperial Cable were illustrated, Mr. Kellaway himself being key-clerk on the occasion. A graceful message was sent to Canada, Fiji, Norfolk Island and Australia and New Zealand, to which an equally graceful reply was received. The power room and the tubes and the methods of internal distribution were carefully "pictured," if that is the word, and the intercommunication switch was given special attention. In the Phonogram Room the methods of accepting telegrams by telephone from the public and of telephoning telegrams to the public were fully illustrated and any of the public who care to watch the lights on the board as they will appear on the screen will see that a very prompt service was given.

Attempts were made to include groups of the chief officers, men and women, in the film, probably successful as regards the women and unsuccessful as regards the men. Throughout the proceedings the staff were wonderfully patient and co-operative. In many cases it was no mean ordeal to have to do one's day-by-day work with the heat close behind one and the purple-white light upon one. Yet it was done, but I have the shrewdest suspicion that if anyone thinks that in the Central Telegraph Office there are large numbers of people who want to be cinema stars and to lead the rest of their days in the blazing light from huge electric lamps and with their faces ruined of any trace of what their Victorian grandmothers would call a complexion, they are strangely mistaken. A tribute must be passed to Captain Calvert and the various officers of the Gaumont Film Company for the thoughtfulness with which the enterprise was conducted and the insight into the complications of telegraph procedure which they displayed. Many of our colleagues up and down the country will see this film and will see us working "at the other end of the wire." We think they will agree that even the humblest of us is more beautiful than he seems to be in the film.

TELEGRAPHIC MEMORABILIA.

COMMENTING upon the recent award of £100 by the P.M.G. to Lt.-Col. A. C. Booth, M.I.E.E., in recognition of improvements in telegraph working and with special reference to the application of the Duplex principle to the Baudot system, the *Electrical Review* remarks: "In a commercial sphere the honorarium would probably have been larger by a hundredfold." It is more than probable; and it is hoped therefore that when the next "Anti-Government," "Anti-Civil Service," or "Anti-Waste" stunt commences, our worthy contemporary and other less level-headed representatives will recall the above and similar instances to mind in connexion with the services rendered to the State by its many servants and will refrain from sweeping criticisms of devoted men and women.

According to *Reuter's Parisian Trade Service*, a Czecho-Slovakian combine controlling a capital of 16 million kronen, 60 per cent. of which is subscribed by the State, has obtained orders for Telegraph and Telephone material from Belgium, Bulgaria, Russia and Yugo-Slavia. All orders in connexion with the public telephone service of Prague have also been placed in the hands of the three companies concerned (all founded since 1918) and now known as The *Telegrafia* Company.

One of the most interesting events in connexion with wireless developments during the month of October was the conference, held in Paris, and attended by representatives of Marconi, the Radio Corporation of America, La Compagnie Générale de Télégraphie of France, and the Gesellschaft fuer Drahtlose Telegraphie of Germany. It is evident that for the future this powerful combination will work in close consultation on all matters affecting mutual interests technically, scientifically, and it is presumed, financially. "A quicker Press service at reduced prices" is suggested by one Press reporter as likely to result from the combined efforts of more rational allotment of wave-lengths and the exchange of the scientific results of laboratory research.

The Italian *Gazzetta Ufficiale* notifies the coming expenditure of 150,000,000 lire upon improvements of the urban and inter-urban telegraph and telephone systems of Italy. No less an additional sum than 16,000,000 lire is to be spent on the erection and systematisation of the telegraph and telephone lines along the railway tracks in course of electrification, viz.: the Turin-Susa, Turin Chieri and Turin-Ronco, and also those lines entering Voghera. Complaints have been received from administrations outside the Italian borders which allege that much of the trouble and difficulty in telegraph working with Italy is due to the close proximity of commercial and transport high-power voltages. Doubtless the experiences gained in running high-power traction, telegraph and telephone lines through the St. Gothard tunnel, for example, will enable the resourceful Italian engineers to reduce to a minimum any possible disturbance due to the, at times, unfortunate proximity of high and low power circuits.

The extension and renewal of telegraph (submarine and land-line) communications steadily proceeds. A direct line between Athens and Broussa is reported as a *fait accompli*, and not without its importance, directly joining up as it does the Greek capital and Asia Minor at a point 57 miles south-east of Constantinople. It has been decided to lay down a new cable between America and Japan, the latest route suggested being by way of the Bonin Islands, Ladrone group, Guam, Midway and Honolulu to San Francisco. According to the *Economic Review* a direct cable may be laid from Bonin to Midway, a stretch of some 2,800 miles. Spain has voted the necessary sum for the laying of a new submarine length from Malaga to Melilla, while the new combined telephone and telegraph cable between Germany and Sweden was successfully placed only a few weeks ago. The work of laying the new cables, already referred to in these columns, as in course of being laid in the East Indian Archipelago by a German company, has also been successfully completed.

According to Signor Giuffrida, the Italian Minister of Posts and Telegraphs, the Government contemplated laying new telegraph cables between the Continent and Sicily, Ravenna and Trieste and Genoa and Nice. Possibly before these lines are in print the Yap-Guam cable will have been opened for public traffic, as it is contemplated inaugurating the Service some time during the Armaments Conference.

Wireless stations are also opening up in all directions, most noteworthy of which stands out "the largest in the world" (W Q K), or Long Island, U.S.A., the working of which was inaugurated by President Harding. From the daily press it is gathered that acknowledgment of the presidential message was instantaneously given by England and immediately followed by Germany.

According to the London *Times*, Berlin has been promised a wireless telephone news service open to all subscribers at an annual rental of £5. It is suggested that banks and newspaper offices would be specially interested. All one has to do is to listen-in at fixed times. This may prove a useful auxiliary to the tape machine and other similar systems, but it would be surprising if the result would be to oust the tape-machine itself. The writer has very direct evidence that the most valuable asset of wire telegraphy is its secrecy. More than one financial interest has complained of the use of *wireless* for the despatch of its telegrams, having very tangible evidence apparently of being preceded in the market by the broadcast nature of wireless transmission.

The *Electrical Review* mentions that the wireless station at Ain-el-Hadjar, near Saida, has just been started by French military engineers. The service will be of a military civil nature, forming a wireless link between France and her African colonies, and providing a stand-by in the event of the breakdown of the Franco-Algerian submarine cables.

A new wireless station is also contemplated for Warsaw with a range of four thousand miles. The work will be carried out by the Radio Corporation of America, and will probably be completed in 1923. Wireless stations are also to be erected at Shanghai, Harbin, Hankow and Pekin in the near future, the contract having been signed, probably by the time this issue appears. At Nijni Novgorod, the manufacture of the essential parts for installing a huge wireless station at Moscow is proceeding apace. This station is destined to signal to any part of the globe. It is also stated by the *Electrical Review* that Russia has already equipped herself with nearly six hundred wireless posts with ranges which permit of complete touch being kept with all parts of Russia, Siberia and Turkestan. The tenders have already been signed between a Melbourne firm and the Australian Navy Department for the general equipment of radio stations at Perth and Sydney. Another big wireless station which is also to be completed in 1923 is that of Katanga in the Belgian Congo, near Elizabethville, whereby direct communication will be obtained between the Congo and Belgium.

According to the South Africa *Telegraph Herald* successful tests of wireless telephony have been made between Cape Town and De Aar, and between Johannesburg and Bloemfontein. Sir Thomas Watt (Minister of Posts and Telegraphs) is reported to have said that "it is satisfactory to know that the public are making more use of wireless telegraphy, and that the system is paying its way." A small wireless station has been set up at Port Elizabeth and working in conjunction with the larger stations of Durban and Slangkop has much improved even if it has not perfected the radio coast communications of South Africa.

Now that high-speed telegraph apparatus has spread throughout the Kingdom and is still spreading, Western Electric, Creed, Baudot, Murray and what not, enquiries are sometimes heard for experienced mechanics well-versed in the intricacies of the mechanism of apparatus such as those above-mentioned. Speaking without prejudice to any other large centre and reviewing the many types of apparatus which have been tried, tested and worked under the same roof from time to time, it would indeed be surprising if the C.T.O. London could not provide the man or men for the job.

The Cable Room staff congratulates Messrs. Tarr and Mitchelmore upon their success in securing well-earned positions in the L.P.S. Messrs. Gibbs, Millett, Thomas and Williams have also been transferred, at least, temporarily, to the Leafield Wireless station.

Consequent on the flux of time the following appointments have been authorised in the C.T.O. vice retirements from the corresponding posts:—

Miss M. McLaren to be Supervisor; Misses A. M. Burrows, E. E. Smith and H. M. Miller to be Assistant Supervisors.

Messrs. J. J. Mansell, G. R. Adams and W. E. Halfpenny to be Superintendents, Section A; Messrs. H. H. Barratt, T. G. Beavis, R. C. Luttrell, and A. F. Reeves to be Assistant Superintendents; and Messrs. A. J. Condy, J. H. Deacon, D. D. Evans, E. Walton, W. K. Ware, and R. P. Mitchell to be Overseers.

The death of Mr. T. Rourke on Oct. 22, after a comparatively short, but terribly painful illness, came as a shock to his colleagues of all grades in T.S. Foreign. "Tom," as he was with the truest affection called, had distinctly an individuality. A very faithful servant of the Department, making no claim to talent or special abilities, he has left a gap which simply cannot be filled. "Always cheerful" is perhaps the simplest yet truest tribute to a sunny nature which spread its happy contagion all round wherever he might happen to be located. Wreaths were placed on the grave at the interment at Abney Park on Oct. 26 from the male and female staffs, Mr. E. Purkiss specially representing the Supervising staff on this sad occasion. A letter of condolence from the Controller was gratefully appreciated by the relatives.

There has been a courteous and informal exchange of ideas and plans between the British and French engineers on the matter of automatic Baudot signalling, the results of which should not be long in evidencing themselves on the Anglo-Continental circuits. The trials on the London-Amsterdam six-channel Baudot of the Booth-Wilmot keyboard perforator transmitter continue to give the satisfactory results expected. The last word in this direction is still to come.

This JOURNAL has rarely to cope with anything approaching severe criticism either inside or outside the Service. Indeed, the appreciation from within has always been and continues to be of the kindliest. It is seldom, however, that one obtains a frank expression of outside appreciation, and it has often been considered an interesting item if we could but "see ourselves as others see us." This opportunity has just occurred, and it comes from one of the scientific branches of the Navy, from an officer now retired, but formerly attached to that most useful but little known branch of our premier defence Service, the Hydrographic Department. During the war this regular subscriber was closely associated with Post Office officials in connexion with submarine cable laying. Writing quite recently, he says:—"Certain it is among your men there are experts of nearly every sort and capable of handling nearly every subject thoroughly. It is the exchange of ideas, exchange of knowledge, splendid spirit of loyalty between master and man which makes your paper so valuable." My correspondent has supplied me with some most interesting matter which we hope to present to the readers of the T. & T. JOURNAL at no distant date. Meanwhile, the kindly helpful spirit in which the proffered information has been placed before us simply enhances the value of our friend's gift.

It is gratifying to publish the fact that the C.T.O. collection on behalf of the Civil Service Life-boat Fund has this year increased by £14 13*s.* 0*d.* on last year. The total amount received through this source for 1921 reaches the handsome sum of £63 13*s.* 0*d.*, of which £27 9*s.* 0*d.* was collected by the ladies.

J. J. T.

SOME NOTES ON SYNCHRONISM.

ONE of the earliest printing systems is the step by step, wherein the positions of the brushes of the two distributors are kept in phase unison by sending over the line a series of reversals which cause the rotating member to step round in unison. The printing pulse takes place when the brushes pause for a definite period. The reversals actuate an electro-magnet escapement movement of the type-wheel preparing its position for the printing pulse. Here we have practically constant correction.

An improvement over this is shown in the Delany Morse multiplex system. In this system a large number of signal segments are used, having correcting segments intermediate at intervals of 60°. This provides for what might be termed intermittent correction, with the correcting impulses occupying a certain percentage of line time.

The next step is seen in the Baudot, where only one correcting impulse per revolution is used. This is an improvement over the Delany in so far as it uses less line time for correcting impulses.

The natural development of using less and less line time for correction is seen in the Western Electric system, wherein no line time at all is taken for special correcting impulses, but correcting impulses are derived from the signals themselves.

The advantage of not having to send special signals to maintain synchronism may be simply explained as follows:—Imagine a telegraph line working simplex which will just carry 1,800 reversals per minute or 30 per second. Let us find out how many words per minute can be carried at this line frequency on a system using two segments per revolution for the transmission of correcting impulses, and a system which requires no special line segments per revolution for correcting. In the case of a quadruple installation, the distributor of the first-named system (Baudot) will require 22 segments—namely, four groups of five for the four sending transmitters, and two segments for correction. Now assume that the segments are connected alternately to + and —, then during one revolution 11 reversals will be transmitted. But as the speed of the line is 30 reversals per second it is clear that the brushes must not be rotated faster than $\frac{30}{11} = 2.7272$ times per second.

In the case of a system which requires no special correcting, impulses such as the Western Electric, only 20 segments are needed, giving 10 complete reversals per revolution. Therefore, in this case, the brushes may be rotated at $\frac{30}{10} = 3$ times per second.

But as each revolution of the brushes sends the same number of letters, that is words per second or per minute, in the two cases, the number of revolutions in a given time is an exact index of the carrying capacity in words per minute.

Therefore, assuming the line conditions to be exactly the same and to be the limiting factor, the carrying capacity of the two systems will be in the proportion 2.7272 : 3. That is, the Western Electric carries 3 - 2.7272 = .2727 more traffic than the Baudot. Now .2727 is 10 per cent. of the simplex carrying capacity of the Baudot which, as shown above, is 2.7272.

In actual practice it has been found that the Western Electric synchronism is more stable than the Baudot, and I shall endeavour to show a reason for this. With the Baudot system, a correcting impulse is received once per revolution, and if the brushes have gained slightly over those at the distant end this correcting impulse acts upon a magnet which steps back or momentarily retards the brushes. This retarding effect is the equivalent of stepping back the brushes 2° or approximately 1 10th of a segment. But now, if the correcting impulse does not arrive at the correct moment, not due to phase displacement of brushes at all, but due to a distortion of the signals, correction will take place when it is not needed, and if such a distortion takes place two or three times in succession the synchronism will be lost.

With the Western Electric method, the correcting impulses are derived from the line signals themselves at the moment when the polarity changes. Now, in this case, should the signals be distorted, we shall receive certain reversals ahead of correct time, and certain reversals later than correct time. But as correcting impulses are generated in both cases, the mean effect of these correcting impulses will be the same as if there were no distortion of line signals at all.

This factor is important, both in the case of underground and aerial lines. The high KR values of underground circuits naturally tend to produce distorted signals as the limit of speed is reached. In the case of aerial lines intermittent contacts will produce slight distortion.

Underground cables have stabilised communication between the large zone centres, but their line speeds are lower than those of the old aerial lines, and therefore, it behoves us to take advantage of every device which will increase the carrying capacity of these underground lines. It has been shown above how 10 per cent. gain (simplex working) can be made without sacrificing any other feature, but instead, actually providing a higher standard of efficiency as regards synchronism.

References have been made to the fact that with Gulstad relays higher speeds can be obtained. This is true. The Gulstad enables a higher frequency of reversals per minute or per second, but when transforming the speed of quadruple transmission in reversals per second into words per minute, the ratio 2.7272 to 3 always remains unchanged.

J. W. TEARE, C.T.O.

"POST OFFICE MANNERS."

THE above heading was given to a short article in the *Daily Mail* regarding the speech by the Postmaster-General on the occasion of the opening of the Toll Exchange. Mr. Kellaway was reported to have said: "It is not sufficient to avoid discourtesy; it is almost an equally serious defect to be off-handed" and that "a good deal of mischief is done to the Post Office by off-handed treatment." After all, off-handedness is rudeness, and now that special attention has been directed to that somewhat common failing of public officials, something may perhaps be done to remove the reproach so far as the Post Office is concerned.

In making arrangements for the staffing of positions where there is direct contact with the public, whether at Post Office counters or the Telephone Exchanges, I would make very careful selection in order to utilise staff who combine efficiency with courtesy, and I would make discourtesy a punishable offence. I do not mean to say that servility is a qualification for such positions. Servility is not a virtue: courtesy is, and should be carefully cultivated. I know that sometimes individual members of the public are very trying to one's temper, but, speaking generally, they may be appeased by the answer courteous. A soft answer turneth away wrath. If you are tempted to return like for like, hesitate and think for a moment, and ask yourself is it worth while? In nine cases out of ten the irate individual will have had the worst of it and will probably be very careful not to "show off" when he again goes to the Post Office or gets through to the exchange.

Mr. Kellaway's remarks referred principally to the experience one gets, all too frequently, from the Post Office counter staff. The counter is where the public gets its first-hand knowledge of Post Office people, it is there, therefore, that the greatest possible forbearance should be exercised. I do not claim to have an excess of the virtue I am advocating in others, but I do say this, the advice I am giving has been acted upon with the best possible results, and I can assure the readers of this JOURNAL that their fellow-humans do really appreciate small courtesies even from the much-maligned Post Office people. Further, it is not fair to those behind the scenes that others should give the impression that *all* Post Office servants are ill-mannered and cross-tempered.

My remarks are intended for all ranks, as I have known even Postmasters to be very ungracious in their manner, especially when speaking by telephone. "Well?" without the "rising inflection" sounds very off-hand on the telephone and makes one think the person speaking would have preferred to say, "Oh, well!" which also sounds funny. According to strength and inflection! The counter, however, is pre-eminently the place where this matter of courtesy requires close attention.

If I may I would like to refer to some early experiences of mine when on counter duties. The incident which first drew my particular attention to the light in which Post Offices were regarded by the public occurred when I was doing duty a branch office at the Docks. An old salt came in to do some business, in which I was able to assist him by giving information which my duty required me to do. When leaving, the old chap took my hand and shook it very heartily saying how much he appreciated my civility.

If space permitted I could relate one or two instances of by-gone days where the tables were turned on discourteous counter clerks who unwittingly were rude to Surveyors instead of the public a case, perhaps, of entertaining angels unawares.

Now, what I have written is not of the kind we usually get in the pages of the TELEGRAPH AND TELEPHONE JOURNAL. It may, indeed, be considered by the Editor as so prosaic as not to be worth printing. However, there is this moral to be gathered from my essay: Civility costs nothing and is its own reward. Those who practise it will generally find that they derive more pleasure from their contact with the public than they would if they were off-hand or rude.

E. T.

[The point is, we think, that if all of us only realise that each act is an act of service to the public, courtesy will follow. Courtesy is the outward expression of an inward attitude.—ED.]

LUMINOUS SIGNALLING APPARATUS FOR POWER STATIONS.

MESSRS. SIEMENS BROS. have sent us a pamphlet (No. 730A) describing their luminous signalling apparatus for power stations in its most recent and improved form.

The complete equipment comprises a transmitting apparatus, a receiving apparatus and a Klaxon horn or other electric calling device.

The transmitter which can be supplied either in a pattern designed for attachment to a wall or suitably mounted on a column is enclosed in a cast-iron case having eight circular windows, on which the orders sent appear by illumination. The transmitter is actuated by means of a movable handle.

The receiver consists of a sheet-iron case with a glass front, upon which the orders received also appear by illumination. A push button switch is provided at the side to enable the engine driver to acknowledge the signal. If desired, this switch can be installed at any convenient position apart from the receiver. An order sent by actuating the transmitter handle is immediately illuminated on the transmitter as well as the receiver, and the call will sound at the receiving end.

The luminous signal will remain visible both on the transmitter and on the receiver, and the aural signal will continue until the engine driver acknowledges the signal by operating the press button switch. As soon as this button is pressed the lamps are extinguished and the circuit to the aural signal is broken. This obliteration of the signal at the transmitting as well as the receiving end serves as an indication to the sender that the signal has been received.

The
Telegraph and Telephone Journal.

PUBLISHED MONTHLY IN THE INTERESTS OF THE TELEGRAPH AND TELEPHONE SERVICE, UNDER THE PATRONAGE OF THE POSTMASTER-GENERAL.

Editing and Organising Committee - - - JOHN LEE. J. J. TYRRELL. W. A. VALENTINE. J. W. WISSENDEN.

Managing Editor - - W. H. GUNSTON.

NOTICES.

As the object of the JOURNAL *is the interchange of information on all subjects affecting the Telegraph and Telephone Service, the Managing Editor will be glad to consider contributions, and all communications together with photographs, diagrams, or other illustrations, should be addressed to him at G.P.O. North, London, E.C.*1. *The Managing Editor will not be responsible for any manuscripts which he finds himself unable to use, but he will take the utmost care to return such manuscripts as promptly as possible. Photographs illustrating accepted articles will be returned if desired.*

VOL. VIII. DECEMBER, 1921. No. 81.

A "LESSON."

WE must confess to some surprise on reading Mr. Ellis Barker's article entitled "The American Telephone and its Lesson" in the *Quarterly Review*. Save brevity, it lacks none of the characteristics which distinguish those articles strictly *ad hoc—hoc* being the disparagement of state telephones—with which we are familiar in certain morning and evening journals. There is all that careless handling of facts and figures, and all that consuming haste to judge after hearing only one side of the case. As our readers are probably well aware, essays in the *Quarterly* are usually headed with a formidable list of works of solid authority dealing with all aspects of the subject under review. What are Mr. Barker's authorities? Firstly, the annual reports of the American Telephone and Telegraph Company, naturally very unfavourable to State ownership of telephones; and from these he quotes largely. Secondly, the recent Report of the Select Committee on Telephones, from which he only quotes two pieces of somewhat hostile evidence. Thirdly, Mr. Herbert N. Casson, the quality of whose history and statistics we have criticised before.

At the outset he repeats the old mis-statement that the City of New York has as many telephones as the whole of the United Kingdom. At the beginning of this year New York had 892,000 telephones and this country 987,000. At the conclusion he states that the "dead hand of bureaucracy" has done the greatest harm to the telephone in all countries except in Sweden—an exception which confirms the rule. "The success of Government management in that country is due to the fact that a business builder of remarkable force and ability, Henry Cedergren, was given a free hand in organising the service." Cedergren, however, organised the service of the Stockholm Telephone Company, and not the State service, which it may be mentioned, owned more than two-thirds of the telephones in Sweden before it acquired the property of the Company. Again, Herbert Spencer is quoted as saying that the telephone was unknown in English cities other than London in 1882. A little research would have shown that Manchester Exchange was opened in 1879 (it is a matter of dispute whether it is the second or third exchange opened in Europe), and during the following two years Liverpool and other towns in Lancashire, Scotland, South Wales, Birmingham, and other places obtained telephone service.

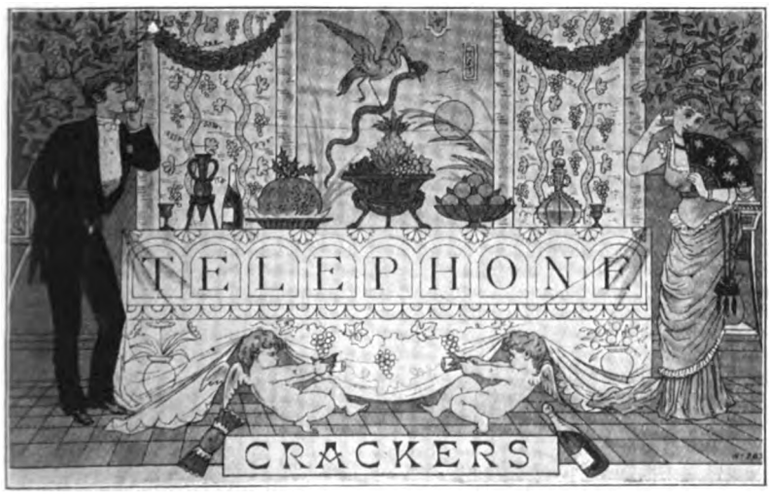
Mr. Barker paints a glowing picture of the telephone in America, and we should be the last to gainsay the splendid development which it has attained in that country. He thinks this is the more noteworthy if we allow for the difficulties under which it suffers. It could well be argued, after studying the other side of the case, that England labours under greater difficulties than America. He enlarges on the exposure of telephone poles to attacks by savages, ants, bears, etc. We concede the bears, and admit that the only savages who trouble us are the "young barbarians" who shy stones at insulators. The British lineman out on the Pennines in winter may have something to fear from snowdrifts, but he is at least not in danger of being scalped. These problems, however, are trifling compared with the difficulties of telephone maintenance in the tree-girt roads and lanes of England. The open character of most American pole-routes is the envy of British telephone engineers.

The universality of the telephone in America is one of the most striking features of its development. Mr. Barker is amazed at the number of farmers on the system, but perhaps he hardly appreciates the difference between the situation of farmers scattered over vast tracts, remote from telegraph offices, and perhaps without postal delivery, and that of a farmer in this country. To the one the telephone is his indispensable link with social life and with the great world; while the other cannot be brought to consider it in this light. We are not altogether surprised to hear that it has put the telegraph in the shade, but our author omits to mention that the telegraph in America is not a State monopoly, and commercial companies are, to put it mildly, not so tender of the interests of remote villages as the State. We are told that one can telephone from one's carriage in the better class railway trains, but telephone experts of the Post Office who have just returned from America declare that this is not so, and that this facility is in the experimental stage. Mr. Barker is filled with admiration for the "particular person" call on trunk lines, but forgets to tell us that it costs 25 per cent. more than the ordinary charge.

Whilst America was at war, the Government "obeying the clamour of the ill-informed" took over the management of the telephones. All the trouble which arose from the withdrawal of telephone staff by enlistment and from the concentration of all energies on war are ascribed to this action. When we are informed that "the former excellent service became totally disorganised," we are left to infer that it was entirely due to the "dead hand."

Mr. Barker quotes a "warning" from an American report of 1912 to the effect no Government telephone system would show a

Digitized by Google



profit under proper accounting methods. Before the war, the two largest telephone systems in Europe, Great Britain and Germany, returned a profit to the Exchequer, and many countries only worked at a loss as a result of these low rates which have so often excited the unbounded admiration of our critics. All these States have since placed or are placing their rates on a basis which will yield a moderate profit or at least pay expenses.

We have perhaps quoted enough to show the kind of "lesson" Mr. Barker thinks is to be learned from America. It is, if we may assemble his well-worn epithets, that the bureaucratic tyranny of a bureaucratically-managed service leads to the strangulation of the telephone system by the dead hand of bureaucracy. It has been taught with equal impartiality by journalists who write for daily papers under a certain pressure of time and circumstance and have not the leisure for that careful research expected from a writer in a learned review. As an example of Mr. Barker's methods we may instance his quotation of Col. Laws Webb's evidence before the Select Committee concerning the ratio of telephone stations to staff. Not the least reference is made to the rebutting evidence of the Post Office witness and the correction of Col. Webb's figures which appear on page 130 of the report.

HIC ET UBIQUE.

"THE result of an experiment by a telephone subscriber in Fulham," says a Sunday paper, "was that out of 175 calls the wrong numbers were given in 70 of them, and none of them was secured in less than 2 minutes."

A man must be very unfortunate to get wrong numbers on 40 per cent. of his calls when the average for all London is about 3.5 per cent., and to suffer a delay of 2 minutes in obtaining connexion when the average time of answer from the exchange is 5 seconds and of connexion with the required subscriber 37.7 seconds; but in the absence of names, dates and details, we can say nothing except to suggest that the figures are of little interest, unless to show how hardly fortune treated the experimenter.

THE picture we reproduce here (kindly forwarded by a correspondent) decorated the cover of a box of Christmas crackers, *circa* 1880 we should imagine, and we publish it as a sort of seasonable curiosity. Indeed, it strikes a responsive chord in the breast of the writer, whose first acquaintance with the word telephone was when his parents brought home a pair of toy telephones (probably from one of those identical boxes) from an evening party. The telephone had just been introduced into this country at that time and was pre-eminently a topical subject.

UNDER the heading "Politeness pays," the *Pall Mall* says: "A telephone operator in one of the offices in the centre of Paris is now a firm believer that "Toujours la politesse" pays. A Spanish gentleman rushed into the room the other day wanting to speak to Madrid. The operator was unusually quick in getting connexion. The charge for the call was ten francs, and the gentleman handed the operator a 100 peseta note, telling him to keep the change. When he took the billet to the money changers he got 180 francs for it, so that his tip was 170 francs!" We are afraid we can draw no moral from this, nor can we see the connexion between politeness and the fact that a trunk line to Madrid happened to be available when the Spaniard made his call. He was fortunate, but we are left doubting whether we are supposed to be instructed or amused.

IN a recent speech the Italian Minister of Posts said:

The unsatisfactory condition of the Italian telephone service was the subject of constant complaint. This used to be attributed to the incapacity of the private companies, but to-day about two-thirds of the telephones were operated by the State and one-third by private companies, and still more than half the communes in Italy were without telephonic communication.

The immediate programme of the Posts and Telegraphs administration was:—

> The completion of the automatic exchanges in Turin, Genoa, Milan, Rome and Naples; the laying of new lines to carry the increased traffic; the connexion of 409 chief towns with the trunk lines; the re-establishment of direct telephonic communication with the principal cities in central Europe; the improvement of audibility between the extremities of Italy; the completion of the laying of trunk lines cables between Milan, Genoa and Turin; and the erection of wireless stations.

The expenditure on the telephone service in 1920-21, without making allowances for depreciation, and interest on capital, was 74 million lire against a return of 68 million lire. Of the 74 million lire 65 were accounted for by staff expenses, that is to say almost 100 per cent. of the returns was expended on salaries. The telephonic charges, especially the reduced rates were to be revised. The Minister estimated the annual deficit of the Posts and Telegraphs for the last three years at about 300 million lire per annum.

"IN connexion with the working of an Imperial wireless organisation," says the *Statist*, "Mr. Donald recently outlined an interesting scheme that deserves mention. He proposes the formation of a British Radio Corporation, organised on commercial lines, having as shareholders the Governments of the States of the Empire, each represented in proportion to the capital subscribed. In addition to directors appointed by the Governments, the Corporation would have on its board representatives of the Admiralty, War Office, etc. The duty of directing the enterprise would be delegated to a small executive committee, consisting of business men, organisers, and engineers. The Corporation would build the wireless chain under contract, retain the ownership, and, after insisting on ample safeguards, lease the working of the system to a company. In this way, it is claimed, and with some reason, that while the pernicious influences arising from State management would be

Digitized by Google

eliminated, the principle of State ownership, so important in an enterprise of the kind, would be maintained."

We are comforted by the tacit admission that the presence of *pernicious influences* would not be detrimental to the work of construction. But, alas, the huge board of directors still has another chance of corruption! The large surplus of pernicious influence might be included in the *ample safeguards* on which they can insist. And what would the supermen and the shareholders do then, poor things?

And why are civil servants a pernicious influence? Many of us avoid the world the flesh and the devil!

CONTRACTS have been entered for the laying of over 800 miles of main cables, of which nearly half will contain telegraph wires. The cables will connect 69 cities and towns with the main underground trunk system, and in addition some 500 miles will be laid in connexion with the development of the local telephone system. These works will provide employment for many thousands of men and women, and thus help towards the solution of the unemployment question.

WE regret that in Mr. F. J. Brown's paper on *Imperial Telegraph Communications*, a line was dropped on page 19 after the final proof was sent to press. After the 26th line from the bottom (right hand column) following the words "stated that," it should read:

"the average load in both directions of some of the most famous foreign stations —*e.g.*, the Bordeaux station, etc."

ANGLO-CONTINENTAL TELEGRAPH COMMUNICATIONS 1914-1921.

BY F. J. BINDER (Cable Room).

IT may be interesting at the present juncture, especially to those who "think internationally," and who wonder how the great land-line communications of the Continent have withstood the vicissitudes of the last seven years, to make a short survey of present facilities and prospects as compared with those existing prior to the war, and to consider separately the position of each of the great traffic-distributing centres most closely associated with the countries affected territorially by the results of the war, and which are served generally from the British Isles by the Government cable system.

As to the types of apparatus which are emerging from the aftermath of upheaval, as worthy to play the important parts which the march of events will inevitably demand, it will be remembered that the decade preceding the events of 1914 had witnessed, especially in France, a distinct movement in favour of the Baudot as a successor to the Hughes on a large number of the more heavily-loaded lines, but—if the recent extent of its adoption is to be accepted as a criterion of its efficiency—the Siemens bids fair to become a formidable rival. This instrument has already been so extensively adopted by the German administration as to constitute it the veritable sheet-anchor of their telegraph system In addition, it is finding favour in Holland, Denmark, Norway, Poland, Austria, Czecho-Slovakia, Hungary, Roumania and Switzerland. It appears to appeal in a peculiar manner to the Teutonic temperament, while the Latins, at any rate for the present, are remaining loyal to their nursling the Baudot. The latter, however, lacks, at any rate at its present stage of development, at least one important qualification, which the Siemens possesses, viz., adaptability for automatic re-transmission. This is an advantage which its organisers well know how to exploit, and one that for geographical reasons has a peculiar attraction for ourselves. Situated as we are, in a relatively detached corner of the Continent, and more distant from the majority of the other members of the European family than any of our competitors on the mainland, we cannot afford to ignore the obvious benefits offered by a system capable of reducing the handicap of distance to a minimum. Indeed the development of the system on these lines, considered in conjunction with a scheme of unity of control, such as enabled the Indo Company to achieve its famous conquests of mileage on the historic London—Tiflis—Teheran line, gives rise to impressions of efficiency hitherto never conceived by the most ardent optimists.

In disposing of traffic for the more remote parts of Europe over the Continental land-lines, it has been the general experience of this country, that as the more southerly latitudes are reached, the services become increasingly difficult, and in cases where the traffic is bound for destinations in the Balkans and south-eastern areas, we have been led to expect the better results, *if transit from West to East is effected prior and not subsequent to transit from North to South*; thus limiting as far as possible, the number of re-transmissions in regions of low latitude. To explain, however, why latitude should thus exercise so potent an influence over the European telegraphs, involving as it would, considerations climatic, geographical, and maybe psychological, would open up a wider field for discussion than it is the purpose of the present article to provide, but the merit of the hypothesis may be exemplified in a striking manner by drawing a line across the map of Europe, from West to East, at approximately the 46th degree of latitude, *i.e.*, from the southern part of the Bay of Biscay to the Black Sea. If the countries be then grouped according as their territory (or the major part of it) be North or South of this line, the result will be as follows:—

Northern Group.	*Southern Group.*
The United Kingdom.	Portugal.
Denmark.	Spain.
Norway.	Italy.
Sweden.	Yugo-Slavia.
The Baltic States.	Roumania.
France.	Albania.
Belgium.	Bulgaria.
Holland.	Greece.
Germany.	Turkey.
Poland.	
Switzerland.	
Austria.	
Czecho-Slovakia.	
Hungary.	

It would be obviously unjustifiable to maintain, on the basis of this partition, that the conditions in any particular country, in either group, were favourable or otherwise, but there can be no two opinions as to which group of States, considered as a whole, is the more capable of improvement.

Berlin's pre-war claim to distinction as the hub of Europe's telegraphic system appears likely to remain unchallenged. To beat her own previous record of direct line communication with 14 countries out of 19 (if Principalities &c. be excluded), would be indeed a creditable achievement, but at the present rate of reconstruction, linked with improvement, even this record appears likely to go by the board. By the end of the year, if the programme laid down be adhered to, all her former correspondents, with the two exceptions of Russia and Turkey, will have resumed direct relations with her. In addition, she can already boast of direct services with three new neighbours in Poland, Czecho-Slovakia and the Danzig Free City. Belgrade, with its recently enhanced status as the capital of a State twice its former size, well deserves the direct connexion which is in course of construction, and it is safe to anticipate that the new Baltic States will not have to wait long for the familiar "Kann Ich bringen" from the German capital.

Bearing in mind the length of the lines, Vienna maintained quite a creditable communication with London before the war, by means of two direct wires, and in many respects this city was admirably situated as a telegraph centre. For some reason, however, the old Austrian administration made no use of Hungarian territory for the purpose of effecting direct relations with countries beyond, and the result was a distinct paucity of lines in the direction of the Balkans. The few that existed straggled over circuitous routes, as was notably instanced by the line from Vienna to Roumania, which in the course of a tortuous journey traversed the full length of Galicia. It is probable that a single line from London will suffice in future for the needs of Vienna. A little of the city's old prestige still clings to it, in spite of misfortunes, and it has not entirely lost its position as a financial and banking centre. The dismemberment of the Austrian Empire, however, has left but a few small provinces to sustain the great and disproportionate capital, which is fated to suffer telegraphically as otherwise.

It is doubtful whether London will renew direct telegraphic acquaintance with Budapest, in any case the old route *via* France, Switzerland, and Austria is not thought to have been sufficiently reliable to invite reconsideration. Provided, however, a fair degree of stability could be assured, a direct communication would prove valuable, especially in furnishing sorely-needed facilities for the more expeditious disposal of traffic for the new Roumania, which country, ranking as it now does, closely after Spain in order of population, and having acquired the oilfields, wheatfields, mineral and agricultural wealth of Bessarabia, Transylvania and the Banat, finds itself in possession of several fine "plums," the picking of which, when ripe, may severely test telegraphic resources in this direction. It is open to question whether the old and interesting route to Asia Minor and what is now Mesopotamia, *via* Budapest and the Turkish land-lines, will be restored, as recent delimitations of frontiers in this area have resulted in the interposition of an additional country (Greece) and consequent higher transit rates, which would deprive the route of its former chief attraction, viz., cheapness.

Among the *nouveaux venus*, Prague (or shall we say "Praha"), as the capital of the most enterprising of the new States, is striving hard for selection as the recognised re-transmitting centre for our Balkan traffic. Not content with having established communication with Paris, Berlin, Warsaw, Budapest, Belgrade, Trieste, Oradeamare (Roumania), &c., she has succeeded in inducing her one-time guardian Austria to part with the better of her two former lines to London, and has achieved the height of a long-cherished ambition—direct working with England. With regard to this consummation, and as a matter of interest, it may be stated that a glance at the names of the offices of origin and the texts of telegrams received over this circuit, might lead the uninitiated observer to suppose, that the birth of a nation had given rise to a mushroom growth of new centres of industry, accompanied by the creation of fashionable

Digitized by Google

spas and watering-places, until it is explained that in the musical tongue and (to ourselves) unintelligible script of our Czecho-Slovak friends, Prague becomes "Praha," Brünn is rendered "Brno," and Carlsbad and Marienbad are expressed as "Karlovy Vary "(or "Karlvary "), and "Marianske Lazne" respectively.

The projected line to Warsaw, serving as it will, for the disposal of traffic for the whole of Poland, should experience but few idle moments. When it is realised that this new state is almost as large as Germany, challenges Italy for fifth place among the European powers in order of population, and contains within its borders Warsaw, the centre of administration and finance, Lodz, "the Manchester of Poland," the former Austrian industrial centres of Cracow, Lemberg (Lwow), and Teschen, together with Posen (Poznan), it will be realised that when once this vast resuscitated empire has accomplished the task of co-ordinating the various laws and systems of the three empires out of which it was formed, and has acquired industrial stability, the volume of traffic will make special calls upon all available communications. The Polish nation has an exceptional interest in the efficiency of its foreign telegraph service in one particular direction, namely, with the United States, the latter country having been the chosen destination of practically the whole of its millions of emigrants. It remains to be seen whether the facilities which the direct communication with Warsaw will have to offer, will prove sufficiently reliable to enable the British Government service to recover its share in the transmission of this traffic, which it was at one time its privilege to enjoy. It is a noteworthy fact, that economic and political pressure have contributed in a remarkable degree to the presence in Warsaw of great numbers of Jews, and no student needs to be told that any centre where the members of this remarkable race think fit to congregate, inevitably becomes the scene of extensive business transactions.

The Anglo-Russian cable to Alexandrovsk (North Russia), equipped at Peterhead with facilities for automatic re-transmission, possesses the distinction of being the longest direct Anglo-European communication. It is no longer a secret that this cable was one of our first war-prizes. It was taken up and re-laid in record time in order to provide reliable communication with our great Slav ally, who would have been otherwise practically inaccessible from the West. It is the opinion of the writer that the prompt disposal of the prodigious volume of traffic (practically all urgent Government despatches) with which the staff operating the cable were entrusted at a time of crisis, represents one of the most meritorious achievements in telegraphic history. A total of 40,000 words a day was frequently exceeded, 52,000 was reached on one occasion, while it might almost be said that the cable itself deserved a diploma. In view of the apparently desolate and inhospitable character of the country traversed by the land-line between Alexandrovsk and Petrograd, it may come as a surprise to many to learn that this particular section has been remarkably free from interruptions, and that except on the memorable occasion when Alexandrovsk was shelled from the sea, no lengthy disturbance has ever been experienced. In case of need an alternative land-line *via* Archangel is available.

It has been a matter of keen disappointment and regret that a communication of such superb carrying capacity, and possessing from a financial point of view, the potentialities of a small gold-mine, should be lying practically unexploited, solely owing to the economic stagnation which has afflicted the vast country it was intended to serve. It is worthy of mention, that the apparatus at the London end is installed as the immediate neighbour of the Imperial cable, so that when occasion demands, the Empire of the West can be provided with a new and important outlet to the East.

(To be continued.)

MODERN WIRELESS TELEGRAPHY AND TELEPHONY.

BY F. ADDEY, B.Sc., M.I.E.E., FELLOW I.R.E

Continued from page 21.

Turner Relay.

In the various types of receiving apparatus which have been described above, the strength of the signals heard in the telephones depends on the amplitude of the oscillations set up by the incoming waves in the aerial and the various circuits associated with it. Strong incoming signals will produce loud sounds in the telephones while weak incoming signals will only produce faint sounds. In the case of valve receivers there is a supply of energy from a local source—the high tension battery—controlled by the weak incoming signals. This causes the loudness of the signals heard to be considerably greater than if the energy given by the waves to the aerial were alone employed to actuate the telephones, as in the simple crystal detector. Such devices are called "amplifiers." The loudness of the sounds produced in the telephones when amplifiers are used is, however, still dependent on the strength of the received signals.

We have now to consider a receiving device in which the effect produced does not depend on the strength of the signals by which the device is actuated, but in which, as long as the strength of the incoming signal exceeds a certain minimum, the same effect is always produced on the apparatus by which the signals are interpreted.

Such a device is known as a "relay," and by suitable design the magnitude of the effect produced can be made very much larger than that of the cause by which the relay is actuated.

Electro-mechanical relays, in which a weak current is caused to excite an electro-magnet, and so to draw over a tongue which then closes a gap in another circuit and permits the passage of a second current, which may be much stronger than that by which the relay was actuated, are well-known in ordinary line telegraphy. We are, however, about to deal now with a device in which the incoming signal is caused to act on a stream of electrons instead of on a mechanical device. It was invented by Mr. L. B. Turner, and is hence known as the "Turner" relay.

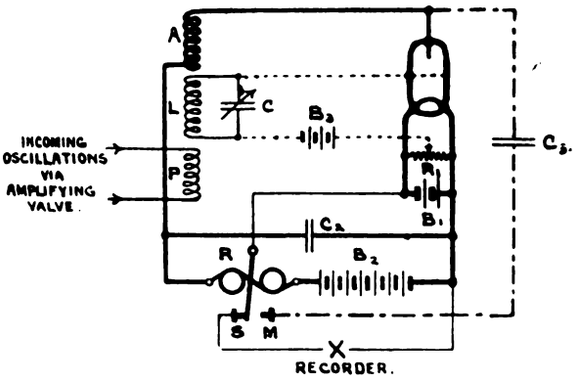


FIG. 19. TURNER RELAY.

The diagram of connexions is shown in Fig. 19. The lead to the anode of the value is taken from the positive terminal of the high tension battery B_2 through the coils of an ordinary relay R, and then through one coil, A, of a triple transformer. A second coil of this transformer, L, has an adjustable condenser, C, joined across it, thus forming an oscillatory circuit, which is tuned to the frequency of the incoming waves.

The plates of the condenser C are joined, one to the grid of the valve and the other to the filament through a potentiometer R, placed across the heating battery B_1. The battery B_3 may be ignored for the moment.

A condenser C_2 is joined across B_2 and R.

It will be seen that we have here an arrangement of circuits capable of producing continuous oscillations, if the correct adjustments be made. One of these necessary adjustments is that the potential of the grid should be brought to a value corresponding to about the middle point of the characteristic curve of the valve, (Fig. 20), already explained in connexion with the circuit shown in Fig. 14 for the reception of continuous waves. In these circumstances, provided the other conditions are suitable, any slight electrical disturbance given to the oscillating circuit LC will raise or lower the potential of the grid, which will increase or decrease the anode current. This change in the anode current will react, through the coils A and L, on the oscillatory circuit LC, and if the coils be joined up correctly this reaction will cause the disturbance already set up in LC to be increased. Each swing of the current in LC will thus cause the next following swing to be greater, and the amplitude of the oscillations will grow larger and larger, the necessary energy being drawn from the high tension battery, till the various losses in the circuit during each swing just balance the energy gained during that swing. The oscillations will then go on with constant amplitude.

Digitized by Google

Suppose now we make the potential of the grid more and more negative, adding, for this purpose, a battery B_3 in the grid circuit with its negative terminal towards the grid. The grid voltage will slide towards the left along the base line of the curve shown in Fig. 20, and finally a point will be reached at which the change in anode current, due to a slight disturbance given to the circuit LC, is not sufficient to produce sufficient reaction on the circuit LC to start the continuous oscillations. As the grid voltage is made more and more negative, a larger and larger initial impulse has to be given to the system to start the continuous oscillations. If, however, a suitably large impulse be given the grid volts will swing up high enough for the necessary change in anode current to take place to produce the required reaction effects on LC and so to maintain the oscillations. When the continuous oscillations are thus set up, the average value of the anode current will be much greater than the anode current which flows while the circuits are quiescent, as can be seen from Fig. 20. Suppose the critical grid potential, at which oscillations just start, to be—2 volts, and that the grid potential be adjusted to some value below—2 volts, say to— 2.4 volts, so that the circuits are quiescent. The anode current will therefore be steady, and its value, as can be seen from the curve, will be .005 milliamperes.

If now a sufficiently strong impulse be received the grid potential will be raised above—2 volts, and continuous oscillations will be set up. The grid potential will swing up and down equally on either side of its normal value of—2.4 volts, to say,+1 volt in one direction and—5.8 volts in the other. The anode current will accordingly pulsate, rising to a maximum of .51 milliamperes when the grid potential reaches+1 volt, and falling to zero when the grid potential has any value below—2.6 volts. The average value of this pulsating current will be .09 milliamperes.

The relay R through the coils of which the anode current flows can be so adjusted that the increased current will draw its tongue over from the spacing stop S to the marking stop M, and some form of recording device placed in the local circuit of the relay may thus be actuated.

The oscillations once started by a single impulse of the necessary strength will go on continuously. For the reception of signals, however, it is necessary that the oscillations should stop when the incoming oscillations stop, and should not continue indefinitely.

This is accomplished, in the particular arrangement shown in Fig. 19, by joining the marking stop of the relay through a condenser C_3 to the anode of the valve. The tongue of the relay is joined to the filament, and so, when the relay is actuated, the valve is short-circuited by the condenser C_3 being joined directly across between the anode and the filament and thus the oscillations are stopped.

The recording device is joined to the *spacing* side of the relay. When the relay is at rest a current from the filament heating battery B_1 flows through the recording device, as can be seen from the diagram. This current is broken when the relay is actuated. The recording device is so arranged that it produces a signal on the *cessation* of the current, and ceases to record when the current flows again.

Thus directly the relay is set into oscillation the relay tongue leaves the spacing stop, and the beginning of the signal is recorded. Directly the tongue touches the marking stop the condenser C_3 is joined across the valve, the oscillations are stopped, and the tongue falls back. But if a signal is still being received the oscillations will be set up again directly the tongue leaves M, and the tongue will therefore at once be drawn back to M. This will continue for so long as a signal is being received, the tongue chattering on M, but, by suitable adjustment, never swinging so far back as to reach S. Thus during the whole of an incoming signal the current from the battery B_1 is cut off from the recorder, and, therefore, as explained above, a continuous signal is produced by the recorder. Directly the incoming signals cease the oscillations are quenched and the relay tongue returns to its spacing stop, thus allowing the current again to flow through the recorder and causing the latter to cease to indicate a signal.

(To be continued.)

LONDON ENGINEERING DISTRICT NOTES.

Institution of P.O.E.E.

A LARGE audience assembled at the Institution of Electrical Engineers on Oct. 18 to hear a paper read by Mr. McIlroy on "The Method of Accounting in the Engineering Department of the Post Office." The close attention given by the hearers was a tribute to the interest with which the lecturer had invested a subject which might, in other hands, have proved to be dry.

Mr. McIlroy dealt first with the manner in which the money spent by the Engineering Department is obtained, and then with the method by which the expenditure of this money is accounted for. After the preparation of the cost statement in the Superintending Engineer's Office had been explained, a description was given of the procedure in the Accountant-General's Department. Considerable emphasis was laid upon the importance of the primary voucher, which is prepared by the workmen and subsequently checked by the Inspector. It was pointed out that this forms the basis of all subsequent operations.

The impression created in the minds of many of the hearers was that the paper could, with advantage, be read at all the Institution Centres, and that if the information could be widely disseminated among the classes concerned in the preparation and checking of the primary vouchers and the abstraction and tabulation of the various items, the work would be done more intelligently and accurately. Moreover, interest would be stimulated, and work which hitherto may have seemed wearisome and futile would become full of meaning.

The discussion that followed was brisk and informative, and one could not help wishing that some of the newspaper critics of government methods could have been present.

It is recollected that during the newspaper agitation last year, a member of the House of Commons wrote a letter to the Department which contained certain criticisms that obviously arose from want of knowledge. An engineering officer interviewed this gentleman and described some of the features of the engineering accounting system with the result that not only were the criticisms withdrawn, but the statement was made that few commercial concerns were in possession of such a thorough system as that in operation in the Post Office, which not only ensured that the authorised expenditure was properly accounted for, but which also enabled the cost of each operation to be readily ascertained.

New Exchange.

On Wednesday, Nov. 2, 1921, the Hendon temporary Exchange was successfully opened with 124 subscribers transferred from Finchley and Kingsbury. 27 incoming and 27 outgoing junctions were provided. On the following Saturday, a further 18 subscribers' circuits were added.

The exchange is housed in an army hut at Queen's Road, Hendon, and has an equipped capacity for 500 lines. The switchboard consists of 7 sections of the P.B.X. type, each equipped with 17 cord circuits.

Two unusual features are the ringing and busy-back circuits. The ringing is obtained by transformation from the electric light supply. The busy-back circuit depends for its action on the alternate polarization and de-polarization of two electrolytic cells, each of which is made up of two iron plates immersed in a solution of caustic soda.

The power plant consists of a 1 h.p. motor, 415 volts 3 phase direct, coupled to the charging generator, two 11 cell batteries of the chloride type, and a charging panel of a type which has been specially designed for use at small exchanges.

The whole of the work of installation has been carried out by the District staff.

Special Cord Circuits for Telephone Repeaters.

A telephonic cord circuit repeater station to be installed at the London Trunk Exchange has been authorised. The switchboard equipment will provide for ten repeater cord circuits and 120 trunks, with their balances, on one section of two positions. Power and testing equipment is being provided for an ultimate capacity of twenty repeater cord circuits, to serve four positions (240 trunks).

Electrophone Amplifiers.

In October, 1919, the application of amplifying valves to electrophone transmission was discussed. It was agreed that the most suitable place to insert the valves was at the Electrophone Exchange. Experiments were carried out, which at the outset gave an amplification of 5-fold without distortion. It was, however, soon demonstrated that defective transmission at the theatre was accentuated by the use of the valve and that the maintenance of the transmitters was a matter of very great importance.

In August, 1920, amplifiers were tried which has separate output circuits for groups of lines of different lengths. A very satisfactory hearing was obtained, articulation being much improved and volume ample with 38 five-mile lines, 32 ten-mile lines and 12 of over ten miles in length on the three output circuits of one amplifier. Finally, a set was experimented with which gave every satisfaction without any special grouping of lines, and this set has been adopted.

As many as 221 subscribers have been connected to one music line at one time, and the advantage of being able to cope with heavy demands for

Digitized by Google

a particular entertainment without having to provide additional music lines, will be apparent.

Ten repeater sets—Repeaters Telephonic No. 5A—are now being installed in the Electrophone Exchange by the Department.

Phonogram Installation. C.T.O.

For some considerable time the question of equipping a complete new phonogram installation at the Central Telegraph Office has been under consideration. Details have now been settled. The whole installation comprising concentrator switchboard and operators' sets will be located on the first floor, G.P.O. West.

The switchboard will consist of four No. 10 type sections, suitably wired for the purpose. At the outset there will be 125 operating sets. There will also be three enquiry positions.

It is, of course, fairly generally known that the phonogram service provides for the receipt at the Central Telegraph Office of telegrams over telephone circuits and the transmission of telegrams by means of telephone to Post Offices for distribution. An extensive pneumatic tube system between the Phonogram Room and the various distributing points in the telegraph galleries will form part of the installation.

Awards for Suggestions.

It is pleasing to note from the latest record of awards granted for suggestions received during the six months ended Sept. 30, that several officers in the London Engineering District are mentioned. The staff at the C.T.O. invariably take a fair proportion of the money awarded. It is noticed that two suggestions in connexion with devices for sharpening punches in connexion with Kleinschmidt perforators were favourably received. One officer received an award in respect of modifications to the ring connexion of switchboard plugs. The fact that after all the years of experience of the working of switchboard plugs, improvements are still possible, should indicate to the staff generally that despite the constant standardisation of plant that takes place, finality is never reached, and that a little thought concerning the efficient operation of tools and apparatus in daily use may, under favourable circumstances, lead to a tangible result in the form of a cheque.

Foreigners and the British Telegraph and Telephone System.

From time to time foreign administrations send to this country representatives to be trained in work appertaining to the Postal Telegraph and Telephone Systems. No doubt the gentlemen selected are chosen because of their special aptitude for the work, but it is surprising how quickly they absorb the information imparted to them, when the complexity of the subject and the language difficulties are taken into consideration.

For some time past a gentlemen from China has been studying the engineering aspect of the work at the Central Telegraph Office, and the answer given below extracted to a question from a paper set with the object of gauging the progress made, indicates not only a facile command of the English language, but a keen appreciation of the ever changing needs of the service.

"*Question.*—Having regard to the trend of the telegraph traffic in Britain, what policy would you suggest to cope with it, as regards the type or types of apparatus likely to prove most suitable.

Answer.—In the light of the present high stage of civilisation, whereby all activities of the human life of all countries have become more closely related to one another, it is a matter of course that the demand for speedy means of communication to satisfy individual and commercial purposes will be ever-increasing as the time goes on.

We students of the telegraph science, are in duty bound to consider seriously the nature of this demand and to seek means to satisfy it to the greatest advantage of the public.

Thanks to the distinguished inventors who have devised various ingenious apparatus and working methods to the telegraph field with the result that we may now be able to form some definite policy to satisfy the public wishes on very economical lines.

It is indeed a great pleasure to examine the development of the telegraph science, from the rough conception of needle telegraph at the very outset to the present stage of high-speed direct type-writing apparatus and from the plain simplex to the complicated multiplex method of transmission. And it is a greater pleasure to note the manner in which the British General Post Office have collected these various systems in one organisation and applied them in their right positions to meet the various circumstances of the community at large.

However, any system which has lived out its fittest time and is no longer compatible with the new requirements created by new circumstances must die its natural death. Thus we see that the earliest form of needle apparatus has become a curiosity in the museum, while others which once played a prominent part on trunk lines have now receded into the unimportant corners.

There is no doubt that the wonderful development of the telegraph science has ushered in the vast amount of traffic; but it is also a fact that the growing traffic has made it an ever-pressing need on the part of the telegraph engineers to mete out improvements to cope with it.

The modern conditions of public resources, have, however, directed our attention to the importance of economical considerations in our fitting out of any system for the public service, while the diversified state of commercial transactions of different localities, as well as the fluctuation of demand and supply in all business centres again necessitates us to provide a system suitable to meet variable circumstances. To satisfy each and every case with the greatest success both to the public and to the management, it is obvious that the system of apparatus must be such as to involve (1) low initial outlay; (2) economy in maintenance; (3) minimum of tear and wear; (4) to provide for automatic type-printing; (5) automatic transmission; (6) means for automatic retransmission; (7) greater range of working efficiency in regard to line variations (8) to possess greater flexibility in speed and (9) to enable errors to be rectified with minimum delay.

So far as the varieties of the existing apparatus are concerned, we have as yet not had one single type that could fulfill all the conditions prescribed. However, as a policy to better meet the present traffic requirements both as regards their nature and quantity, the Baudot multiplex and the Wheatstone automatic associated with the Creed apparatus will be found to approach nearest the mark of the ideal type, pending further development of either of the two systems themselves or of the telegraph science in general.—Oct. 20, 1921."

Telegraphs.

One triple duplex Baudot set has been installed during the past month on one of the Amsterdam circuits. This now gives Amsterdam two triple and one double duplex sets. A similar set has also been provided on one of the Brussels lines in place of a double duplex.

Hughes circuits to Paris Bourse and to Amsterdam Bourse have been provided at the London Stock Exchange Office. This is an interesting note of development inasmuch as direct telegraph working to the Continent is an entire innovation at the "Stock."

Metropolitan Special Constabulary Reserve. Post Office Division.

Several members of the District staff received the long-service medal from H.R.H. The Duke of York at the Parade in Hyde Park on Oct. 2. 1921. The medals were awarded in recognition of three years' voluntary service on police duties during the war period.

Several other members of the Reserve have qualified for the medal and will receive it at a later date.

NOTE.—In the article on "The Central Telegraph Office Section London Engineering District" on page 30, the wording beneath the second and third photographs was transposed. The first represents the Auxiliary Phonogram Room, and the second the Cord Carriers and pneumatic tubes.

LONDON TELEPHONE SERVICE NOTES.

Armistice Day at the Controller's Office.

AN impressive ceremony took place at Queen Victoria Street, at 11 a.m. on Nov. 11. The idea of commemorating the occasion of the third anniversary of the 1918 Armistice originated with the London Telephone Service Whitley Committee, who were responsible for the arrangements.

Shortly before 11 a.m. representatives from all sections of the staff assembled before the Rolls of Honour in the Public Lobby. The Controller and his chief officers took up their positions on the stroke of the hour, and the two minutes' silence was observed. The tension was relieved at last by the report of a maroon, and after a short address on the significance of the solemn occasion, the Controller placed beautiful, yet simple wreaths under the respective Rolls of Honour, the wreaths being handed to him by representatives of the two sections of the staff for decorating the Women's and Men's Rolls respectively.

On the following Monday, the Controller, attended by representatives of the staff, deposited a wreath at the Cenotaph as a tribute to the memory of colleagues who gave their lives during the Great War.

An Office Match.

It is not often our pleasure to record a marriage between members of the staff, but such an event took place recently when Mr. E. H. Gimber of the Accounts Branch took unto himself Miss M. E. Grigg of the same branch. The bride was presented by her colleagues with a silver tea service, and the bridegroom with a handsome oak clock. The wedding took place at St. Luke's Church, Battersea.

City Traffic District.

The City Traffic District Office Annual Dance was held on Oct. 29 at Australia House. All the exchanges were well represented, and the Traffic Branch and Secretary's Office also provided support.

The music was of an excellent character, and a feature of the function was the energy displayed by the dancers, few of whom failed to participate in every item. The M.C.'s were Messrs. J. Webb and R. T. Gregory. At its conclusion, everyone agreed it had been a most enjoyable evening. It is unfortunate that a larger hall could not be obtained, as there was keen competition for the 280 tickets issued, and twice that number could have been disposed of. The promoters have doubtless made a note of it.

London Telephonists' Society.

The second meeting of the London Telephonists' Society was held on Wednesday, Nov. 2, when a debate was heard between Messrs. H. G. Corner and H. Dive on the subject "Has the Telephone added to the sum of Human Happiness?"

The weather capriciously chose the night in question for one of its worst exhibitions; but in spite of this, the reputation of both speakers was sufficient to draw large numbers to the debate.

Mr. Dive opened with the affirmative side; and in a brightly written paper showed, with his accustomed ingenuity, that the telephone satisfied the definition of happiness as given by such authorities as Confucius, Emerson and Dr. Johnson, while his picture of the telephone as the one thing lacking in the romance of Ulysses and Penelope and of Richard and Berengaria, convulsed his hearers even if it did not convince them.

Mr. Corner followed, and in a few moments took his audience back eight thousand years. He contended that this, the Mechanical Age, had not brought happiness in its train; that our modern inventions had brought instead destruction and disaster; that retrogression had taken enormous strides during the last 150 years as compared with the previous 8,000; and that we should not be really happy again until we got back to the beautiful and simple things of life.

It is hard to resist the belief that Mr. Dive really agreed with him. It is even being whispered that next session the two counsel will exchange briefs.

A number of speakers took part in the discussion. The Chairman summed up, and a member of the audience demanded a division. A vocal expression was invited, and although the Chairman's ruling was that the "Ayes" and "Noes" were equal, the "Noes" certainly produced a greater volume of sound.

* * * *

The December gathering of the Society takes the form of a Dance, which will be held at the Bishopsgate Institute on New Year's Eve.

* * * *

Langham Choral Society.

The Society's first concert of the season took place on Armistice Night. The programme, consisting of Stanford's "At the Abbey Gate," Beethoven's "Mass in C," and Elgar's "Banner of St. George," was very exacting, being almost entirely choral. From the artistic point of view and judged by the criticisms in the public press, the performance of these works was eminently successful, but whilst the concert was well attended, the hope that the Queen's Hall would be filled to overflowing, in view of the intention to hand the profits to the "Not Forgotten Association," was not realised.

The Society's next performance will be at Queen's Hall on Jan. 24, when "Elijah" will be sung. If this note meets the eye of any male vocalists (especially tenors), who would care to assist, perhaps they will get into touch with the Hon. Secretary, Miss W. M. Nurse, 61, Shalftesbury Avenue, who will be pleased to give them further particulars. Members of the Engineering staff will be particularly welcome.

* * * *

Culled from the Exchanges.

The collaborators in these notes have invited the staffs at the exchanges to send along items of interest with a view to having them included in these columns. This has already borne fruit, and the following items have been received:—

East Exchange.

The East Swimming Gala was held at Poplar Baths on Thursday, Oct. 20. All the events were desperately contested, and the spectators were kept at a high pitch of excitement. The results were:—

Ladies' Team Race.
London Wall Exchange beat East Exchange.

Open Team Race.
Avenue, Central, Gerrard and London Wall Exchanges, won by Central.

Men's Team Race.
Denman Street beat East.

Ladies' Club Handicap.
Miss Brinsden 1. Miss Jones 2.

Men's Club Handicap.
Mr. A. J. Woolner 1. Mr. A. Crooks 2.

Ladies' Club Championship.
Miss Jones 1. Miss Brinsden 2.

Men's Diving.
Mr. W. Crooks 1. Mr. Sinclair 2.

* * * *

Mayfair Exchange.

On Saturday, Oct. 22, Australia House was the rendezvous of those who supported the dance arranged by the Mayfair Exchange.

The dance, which was the first held by Mayfair this season, was most successful, and all who were fortunate enough to be present found everything arranged to provide for their comfort and enjoyment. The dance music provided by the excellent "Bon Accord" Band and the good floor and hall, combined to make terpsichorean exercise a true delight. The dancers were indebted to Mr. J. E. Collins, who was an efficient and amiable M.C. Another dance is arranged for Saturday, Dec. 10.

East Ham Exchange.

The following is extracted from the Annual Report of the Penny Association and Guild of Nurses, associated with St. Mary's Hospital (Plaistow) for Women and Children:—

"The staff of the East Ham Exchange, by whose wish no names are to be published—not only have they sent £25, the proceeds of their concert, but at regular intervals some of them visit the patients, and they never arrive empty handed, but are laden with all sorts of things—jellies, flowers, books, &c., all of which are most acceptable, and the patients love their visits."

* * * *

Regent Exchange.

A very interesting letter on the subject of the JOURNAL has been received from Regent Exchange, and as it contains many suggestions for including items which may tend to make the JOURNAL of greater attraction to the fair sex, it has been forwarded to the Editors. It enclosed the drawing by Mr. A. E. Niblock, which is here reproduced.

It is said that the following actually happened at Regent:—

SUPERVISOR (*speaking on head-set of bewildered learner*): "Is there anything wrong with your pilot?"

BEWILDERED LEARNER: "What did you say?"

SUPERVISOR: "Is there anything wrong with your pilot?"

BEWILDERED LEARNER: "Sorry, I cannot hear you."

SUPERVISOR (*with emphasis*): "Is there anything *wrong with your pilot*?"

BEWILDERED LEARNER (*appealing to the adjacent telephonist*): "What must I say? There is somebody on here asking me if I am Pontius Pilate?"

* * * *

Walthamstow Exchange.

The staff at Walthamstow made a presentation to Miss F. G. Hutt, the Supervisor-in-Charge, on the occasion of her transfer to East Exchange. The gift was a tangible form of expressing the staff's deep appreciation of the assistance and guidance they had received from their chief and counsellor.

HAS THE TELEPHONE ADDED TO THE SUM OF HUMAN HAPPINESS?—A SIDELIGHT ON THE DEBATE.

BY F. L. SANDERS.

IT will be remembered that the debate between Messrs. Dive and Corner terminated with opinion fairly equally divided, neither speaker having produced sufficiently conclusive evidence in support of his particular point of view.

It is the intention of this article to convey to those interested in the subject another and perhaps wider aspect, the argument being in favour of the telephone—and in support of Mr. Dive's contention—and based upon the plain, solid, historical fact that the telephone played a most important part in the Great War, and was in no small degree responsible for its termination, and incidentally, for the condition of peace we enjoy to-day.

The particular incident I have in mind took place somewhere in September, 1914, about the time of the Battle of the Marne. It will be remembered that French troops were rushed from Paris by taxicab to the support of our so-called Contemptible Army when it was in real danger of annihilation during the great German bid for Paris.

It is of course well known that the combatants utilised the most modern methods of mechanical and chemical warfare but, as demonstrated, it was primarily to the use of mechanical aids that the French were enabled to reach the line.

The only possible manner in which those in authority at Paris could have known in time to take adequate steps to render the necessary assistance to their British ally was by means of wireless or telephonic communication. The distance from the line was such that it would have been impossible even with existing mechanical aids to have travelled to the capital and organised a force which could have arrived in time to have saved our Expeditionary Force.

Yet it was accomplished: the French troops arriving at the psychological moment to assist in stemming the advance of the so-far victorious enemy and definitely closing the road to Paris.

Now this is where the connexion between the telephone and human happiness becomes apparent.

What might have happened had the enemy reached Paris it is difficult to say, but it has been hazarded that a repetition of the disastrous agreement of 1870 would have taken place, leaving the enemy free to devote his attention to ENGLAND—and at the same time free to perpetuate in Northern France what they practised in Belgium—Louvain, Liege, &c.

Had the German Army succeeded in the first part of their ambitious schedule and gained Paris, they would have had at their disposal a seaboard eminently suitable for the basis of submarine operations against this country. Our Navy upon which we relied as the premier line of defence would have probably found itself engaged upon tasks other than that of patrolling the North Sea and enforcing an economic blockade. In this event there would have been considerable diminution of force available for combating the "High Seas" fleet in any attempted raid on our coasts, incidents which in themselves would have been in no way conducive to the happy sense of security which we had hitherto enjoyed.

Undoubtedly the happiness of the world was in jeopardy when the Germans made their first bid for Paris, but the use of the telephone—wireless or manual—frustrated their machinations to enforce their kulture on the rest of the world, and by so doing definitely established a relationship with human happiness in the widest sense.

Is it necessary to ask then, "Has the telephone added to the sum of human happiness?" when the two are so indissolubly bound together? There can be but one answer—YES!

ABOUT STATISTICS.

BY H. MORGAN (*Contract Branch, L.T.S.*).

MOST of us are well content to let "X" equal the unknown quantity. There are, however, quite a number of the people who look upon the compilation of statistics in the light of a hobby, hence we have it placed upon record that "A stitch in time saves nine." The *modus operandi* by which the final result was obtained in this case is not stated, but the mathematical exactitude of the computation has not, so far as is known, ever been disputed by anyone except an itinerant vendor of bachelor trouser buttons.

Some statistics, like "sea serpents" and "grave warnings," run in seasons. The public thirst for knowledge in this particular direction is assumed by the journalistic fraternity to coincide exactly with a shortage of good copy, and it is in these circumstances that the assumed insatiable desire for information is generously and fully satisfied.

Statistics cover the whole gamut of commercial activity and it is therefore manifestly impossible here to do other than treat with just a few of the methods of computation more directly appertaining to the Post Office telephone system.

A large number of operations, the result of which were carefully tabulated before the war, have since been discontinued, and they have been neither missed nor mourned. Shakespeare said "Let's talk of graves," but if the telephone had been in vogue in his day, he might have said, "Let's talk of curves," for the Traffic Branch has developed curve plotting to a fine art, and can, therefore, talk authoritatively and in a clear well-defined manner about percentages of ineffective calls, peak loads, &c., &c. One chart shows at a glance the equated calls and number of telephonists operating at any given exchange switchboard during each half-hour for the twelve hours of the day; another provides the basis for the provision of equipment, and yet another computes the absences for relief purposes and other reasons. In fact it is safe to say that the marked efficiency which characterises the administration and supervision of the Traffic Division is due in a very large measure to the definite and material facts elicited from the carefully compiled curve-plotted charts.

The contents of the card cabinets in the Contract Branch make it possible to calculate correctly the cessation cases and the number of outstanding applicants in the various areas affected by plant shortage; while the forms C.M. 25 and T.P. 1045, fearsome documents as they are to the uninitiated, make clear and plain to the Superintendent of Contracts the results of the activities of his subordinates.

Development study, which is also based upon squared maps and charted areas, has been very ably described and profusely illustrated in this JOURNAL, so needs only to be mentioned in this connexion as a further proof of the extreme value of methodical computation as a basis both for present and future capital expenditure.

In the Rental Branch where statistics of a more permanent character are essential, the Ledger or Register system obtains. In the case of outstanding amounts, however, it has been deemed advisable to plot a curve chart.

But enough has been written to show that the compilation of reliable statistics is an essential part of the routine of any Administration or Department where lucidity of operation and control, is a synonym of success.

THE "ELECTRICIAN" DIAMOND JUBILEE NUMBER: NOVEMBER 11, 1921.

SIXTY YEARS OF ELECTRICAL PROGRESS.

THE history of *The Electrician*, which first appeared on Nov. 9, 1861, and has just celebrated its Diamond Jubilee, is the history of a great change no less in technical journalism than in electrical engineering. In those sixty years it has recorded such inventions, designs and commercial enterprise as in 1880 made electric lighting possible and later spread a network of supply mains through all our large cities. In 1890 it marked the genesis of electrical traction on the City and South London Railway. It has seen the invention of the telephone and the widespread adoption of the electric motor for industrial purposes. It has recorded the pioneer work of Marconi, Hertz, Lodge and Fleming which culminated in the invention of commercial wireless telegraphy. Its pages are a chronicle of the transformation of electricity from a little understood science not only into a great industry but into a means of improving our present civilisation. For by electricity the dream of the servantless house becomes an actuality. That is a sufficient example of what it can do for everyone.

SHROPSHIRE PHILOSOPHICAL SOCIETY.

AT the inaugural meeting of the newly-formed Shropshire Philosophical Society, held at Shrewsbury on Oct. 29, Mr. T. Plummer, M.I.E.E., Superintending Engineer, North Wales District, read a paper on "Thermionic Valves as used in Long-Distance Telephony." The paper, which was fully illustrated by lantern slides and working apparatus, gave a description of the difficulties met with in long-distance telephone transmission through the attenuation and distortion of the speech currents, and how these have been mitigated by the loading of underground circuits, and, more recently, by the use of thermionic valve amplifiers in telephone repeaters. Information was given respecting the economies in cost of line plant resulting from the use of telephone repeaters, and of the extensive programme of new underground main cable routes, either completed or in coruse of construction by the Post Office.

CALENDAR OF COMING EVENTS.

Dec. 7. } —C.T.O. Benevolent Fund "Interkom Club" presents "The
" 8 } Tempest" at Guildhall School of Music on behalf of Alexandra Orphanage.

" 16.—Society of Civil Servants. "Routine and the Civil Servant," Miss Millicent Murby, Ministry of Health.

" 19.—Telegraph and Telephone Society. (1) The Telephone Service; Suggestions for Improvement, Miss A. Flanagan. (2) The Night Telephone Service; some of its problems. Mr. Ernest J. Lansbury.

FOOTBALL (CENTELS).

Dec. 8.—Notting Hill Police (Home) 1st Team.
" 22.—Ravenscourt Amateurs (Away) 2nd Team.
Jan. 5.—Harlesden Town (Home) 1st Team.

MISS BELL.

MISS DONALD.

GLASGOW.

RETIREMENT OF MISS BELL.

IT is with great regret that the retirement of Miss R. S. Bell, Assistant Supervisor, Class 1, Glasgow Trunk Exchange, on account of ill health has to be chronicled. Miss Bell transferred in 1896 from the ex-National Telephone phone Company to the Post Office Trunk Service, and she may therefore be classed as one of the pioneers in the Service. From a small beginning she has seen the Glasgow Trunk Exchange grow to its present proportions. Miss Bell was a keen and zealous officer and the efficiency of the Trunk Service was a matter very dear to her heart. In token of the esteem in which she was held, Miss Bell was presented at her home on Oct. 10 with a handsome beaded bag lined with Treasury notes. On Oct. 28, a tea party and musical evening was given in her honour in the Athenaeum by the Trunk Exchange staff at which several of Miss Bell's old colleagues who were in the service in 1896 were present. Miss Donald, the Trunk Exchange Supervisor presided and a most enjoyable evening was spent. The music was entirely sustained by the present Trunk staff.

Miss Bell carries the best wishes of the staff into her retirement, and it is hoped that she will enjoy her leisure for many years to come.

RETIREMENT OF MISS DONALD.

MISS MARY DONALD, Assistant Supervisor, Class 1, in charge of the Douglas Exchange, Glasgow, resigned the service on Oct. 20 in view of her approaching marriage. Miss Donald has had the unique experience of serving under three telephone administrations. She entered the National Telephone Company, and from there migrated to The Glasgow Corporation Telephone Department as a Supervisor. When the Government took over the Corporation telephones in 1906. she was transferred to a third Administration. Miss Donald was a very capable Supervisor and performed her duties faithfully and successfully She was the recipient of a case of cutlery and fish servers from the Douglas staff and her old staff in the Central Exchange presented her with a case of fish knives and forks. Miss Donald carries the best wishes of the staff for her future happiness and it is hoped that she will not forget the old scenes when she settles in Shanghai.

MR. SUTCLIFFE'S RETIREMENT.

We should like to add to the account of the presentation to Mr. Sutcliffe, recorded on page 23, that besides the gifts mentioned, Mr. Sutcliffe received a handsome suit case from the Bradford engineers, together with a scroll signed by every contributor, a drawing-room easy-chair from old National Telephone friends, and from the Bradford Exchange supervisors, pipes and slippers in addition to the contribution to the general presentation.

GOLF.

SECRETARY'S OFFICE *v.* STORES DEPARTMENT.

Played over North Surrey Course, Oct. 4, 1921.

LONDON TELEPHONE STAFF.

Resignations on account of marriage :—

Miss G. E. EVERARD, Supervisor, of Bank Exchange.
Miss E. HOLLINGTON, Telephonist, of Museum Exchange.
Miss B. M. WOODHAMS, Telephonist, of Purley Exchange.
Miss M. A. DIBBLEE, Telephonist, of Victoria Exchange.
Miss M. I. L. SAYER, Telephonist, of Victoria Exchange.
Miss A. F. WRIGHT, Telephonist, of Victoria Exchange.
Miss L. E. MERMOD, Telephonist, of East Exchange.
Miss T. S. M. SANDERS, Telephonist, of Kensington Exchange.
Miss E. M. WAITE, Telephonist, of Woolwich Exchange.
Miss D. M. WALKER, Telephonist, of Central Exchange.
Miss A. A. HOGG, Telephonist, of Central Exchange.
Miss G. A. HARVEY, Telephonist, of Central Exchange.
Miss M. V. EDRIDGE, Telephonist, of Regent Exchange.
Miss E. L. POOLE, Telephonist, of Regent Exchange.
Miss W. R. L. TRINDER, Telephonist, of Hornsey Exchange.
Miss D. B. DAVEY, Telephonist, of Trunk Exchange.
Miss V. S. M. SELLS, Telephonist, of Trunk Exchange.
Miss L. M. FRANKS, Telephonist, of Trunk Exchange.
Miss D. CHEESMAN, Telephonist, of Trunk Exchange.

CENTRAL TELEGRAPH OFFICE.

PROMOTIONS.

Mr. J. J. MANSELL, Assistant Superintendent, to Superintendent, Section A.
Mr. G. R. ADAMS, Assistant Superintendent, to Superintendent, Section A.
Mr. W. E. HALFPENNY, Assistant Superintendent, to Superintendent. Section A.
Mr. H. H. BARRATT, Overseer, to Assistant Superintendent.
Mr. T. G. BEAVIS, Overseer, to Assistant Superintendent.
Mr. R. C. LUTTRELL, Overseer, to Assistant Superintendent.
Mr. A. F. REEVES, Overseer, to Assistant Superintendent.
Mr. A. J. CONDY, Telegraphist, to Overseer.
Mr. J. H. DEACON, Telegraphist, to Overseer.
Mr. D. D. EVANS, Telegraphist, to Overseer.
Mr. E. WALTON, Telegraphist, to Overseer.
Mr. W. K. WARE, Telegraphist, to Overseer.
Mr. R. P. MITCHELL, Telegraphist, to Overseer.
Miss M. MCLAREN, Assistant Supervisor, to Supervisor
Miss A. M. BURROWS, Telegraphist, to Assistant Supervisor
Miss E. E. SMITH, Telegraphist, to Assistant Supervisor
Miss H. M. MILLER, Telegraphist to Assistant Supervisor.
Miss I. WRIGHT, Telegraphist, to Assistant Supervisor.

MR. T. A. BATES TRANSFERRED TO LEEDS.

Mr. T. A. Bates, the district manager of the Post Office telephone ervice in Bristol, has just obtained well-deserved promotion, has taken up similar duties in the Leeds district, which contains over 33,000 telephone stations, and is the largest automatic exchange in the country. Mr. Bates, who is a Lancashire man, was educated at Uppingham and joined the Bristol district as manager in November 1915. Mr. Bates will be missed by the Bristol Musical Club, of which body he has been a member for some years. Mr. Bates will be succeeded as district manager by Mr. Crawford Millar, at present in charge at Gloucester. A large and representative gathering of members of the Post Office Telephone Staff was held to bid farewell to Mr. Bates. The chair was taken by Mr. Mayo Smith, Chief Clerk.

The chief feature of the evening was the presentation by Mr. F. C. Luke (Postmaster-Surveyor) to Mr. Bates of a gold wristlet watch suitably engraved. In making the presentation, he referred to his earlier association with Mr. Bates in Scotland and latterly in Bristol. He alluded to the happy feeling existing in all sections, and pointed out how gratified he was to be at the head of such an efficient staff. He said he had evidence of this from an important meeting held recently in Bristol by the Chamber of Commerce, who highly commended the service of the trunk and local departments. Mr. Luke then presented Mrs. Bates with a very handsome handbag. Miss Dean, a junior member of the staff, presented Mrs. Bates with a handsome bouquet, and Mr. Eldridge, superintending engineer, handed to Mr. Bates a Malacca gold-mounted walking-stick and silver pencil on behalf of the engineering staff of the district.

Mr. Bates warmly thanked those present for their kindly expressions and handsome presents, which, he said, he would ever treasure as tangible tokens of the friendship which existed between them.

UNVEILING OF WAR MEMORIAL TO MEMBERS OF THE SECRETARY'S OFFICE.

A WELL-ATTENDED service was held on Dec. 1 in Christ Church, Greyfriars, in memory of the members of the Secretary's office who gave their lives in the service of their King and Country in the Great War. Following an anthem rendered by the L.P.S. Male Voice Choir, the Bishop of London gave an eloquent address on the subject of "Hope." After the service the ceremony of unveiling and dedication of the tablet which has been erected in G.P.O. North was inaugurated by a short speech from the Secretary Sir Evelyn Murray, K.C.B., who asked the Postmaster-General to unveil the tablet. The Bishop of London then dedicated it, saying

> O Lord, we beseech Thee of Thy merciful goodness to accept this offering, which we make to Thy glory, in thankful remembrance of those who, at the call of King and Country, left all that was dear to them, endured hardness, faced danger, and finally passed out of the sight of men by the path of duty and self-sacrifice, giving up their own lives that others might live in freedom; we ask it in the name of Jesus Christ our Lord. Amen.

The ceremony concluded with the Bishop's blessing, the Last Post, the Reveille and the National Anthem.

COMBINED WIRE AND WIRELESS TELEPHONIC COMMUNICATION WITH AMSTERDAM.

AN interesting demonstration was given by the Marconi Company on Sunday, Dec. 18, when telephonic communication was obtained between Marconi House, London, and the Stock Exchange, Amsterdam, by means of the land-circuits between London and Southwold and between Zandvoort and Amsterdam combined with wireless transmission across the North Sea. The writer carried on a short but very satisfactory conversation with a speaker in Amsterdam 250 miles away.

The wireless transmitting stations at Southwold and Zandvoort were equipped with valve transmitters, the receiving stations in both cases being situated adjacent to the transmitting stations, but separated by a distance of about 100 yards in order to provide effective duplex working. Speech from London reaches Southwold over a metallic circuit, placed at the disposal of the Marconi Company on this occasion by the Post Office, and is received there in a much attenuated form. It is passed through a special "bridge" circuit and then amplified by thermionic valves to its original London length, after which it is caused to control the carrier wave emitted from the transmitting station. At the Dutch receiving station the speech variations in the carrier wave are received and amplified and after rectification the speech currents are again, on a local metallic circuit, at London strength. The local circuit at the Zandvoort receiving station is connected through another "bridge" to the Amsterdam trunk line of the Dutch Government and the London-Amsterdam circuit is thus completed.

The Amsterdam-London circuit is not affected by the London-Amsterdam circuit so that conversation can be carried on to and fro in the ordinary way. This is made possible firstly by working to Holland on a slightly different wave-length to that used for the return communication and by separating the transmitting and receiving stations at each end, and secondly by the special "bridge" connexion.

Should the difficulties of extending this form of communication at each end to subscribers on the English and Dutch telephone system be overcome, some very interesting developments would result.

P.O. SANATORIUM SOCIETY.

L.T.S. CONSTITUENCY COMMITTEE.

A COMMITTEE meeting was held on Thursday, Dec. 15, at the Controller's Office, at which the members discussed with interest a proposal to raise a sum of money, which could be used to cheer our colleagues who are temporarily "off duty" owing to illness.

Early in the present year three members of the Committee had the advantage of visiting the National Sanatorium at Benenden, Kent, and of seeing for themselves how well our people are treated there. But we all know that good treatment is one thing and a little friendly cheer is another, and the L.T.S. Committee are hoping that it may be possible to do something, for example, to increase the recreation facilities of our friends at Benenden. Even such a small thing as a supply of magazines, newspapers, etc., might be a friendly link between them and their fellow workers in town. However, this suggestion and others which have been made will be discussed in more detail, when the result of an appeal, which it is hoped to make early in the New Year, is known.

The L.T.S. branch of the P.O. Sanatorium Society is one of the most recently formed, but it is also one of the largest in the country. Its membership is now about 70 per cent. of the total staff, and the Committee feel it is their duty to follow the good example recently set by the C.T.O. and several of the Postal District Offices, and to do something to really justify their existence.

They hope this foreward may awake a feeling of interest throughout the L.T.S., and that the splendid efforts, especially of the Exchange staffs, in other directions, may be turned for a short time to a fresh cause.

THIRD ANNUAL DINNER OF THE WESTERN DISTRICT CONTRACT OFFICE.

THE Third Annual Dinner of the Eastern District Contract Office was held at Pritchard's Restaurant, Oxford Street, on Nov. 18, 1921. The District Contract Agent, Mr. W. V. Pegden, in the Chair, was supported by the following guests:—Major G. F. Preston, C.B.E. (Controller, London Telephone Service); Mr. W. A. Valentine (Deputy Controller); Mr. J. Stirling (Assistant Controller); Mr. W. Bold (Superintendent of Accounts); Mr. W. F. Taylor (Superintendent of Contracts); Mr. A. J. Sharpley (Sectional Engineer, Centre External); Mr. F. J. Phillips (Sectional Engineer, West External); Mr. F. Woollard (Sectional Engineer, Centre Internal).

A most enjoyable evening was spent and an excellent dinner was followed by a musical programme contributed by members of the staff, the artistes being Messrs. W. V. Pegden, H. Neil, W. Horlock, S. W. Swain, C. F. Bradshaw, W. R. Child, F. G. Evans, and W. C. P. Barnard. A display of conjuring by Mr. J. E. Williams was also much appreciated.

Between the items the following toasts were honoured:—The King; The Western District Contract Office; The London Telephone Service; The Visitors and the Chairman. The work of the London Telephone Service during the past year, with especial reference to the Western District Contract Office, was brought under review and excellent speeches were given by Major G. F. Preston, C.B.E., Messrs. A. W. Valentine, J. Stirling, W. F. Taylor, A. J. Sharpley, W. V. Pegden and S. W. Swain.

A very successful evening closed with the singing of "Auld Lang Syne."

PRESENTATION OF IMPERIAL SERVICE MEDAL TO MR. RICE.

ON Dec. 9 Mr. S. V. Rice, formerly Adult Messenger in the L.T.S. was presented by the Controller with the Imperial Service Medal. Mr. Rice served for 35 years in the Post Office and was retired on account of ill-health in November last year. His Majesty the King has expressed the wish that the Imperial Service Medal should be presented personally by the Head of the Department in which the recipient last served, and this was accordingly done in the presence of the Controlling Officers and representatives of Mr. Rice's old colleagues.

OBITUARY.

THE LATE MR. C. W. BLACKBURN.

MR. C. W. BLACKBURN, Clerical Officer, District Manager's office, Telephones, York, died on Sunday, Nov. 13, after a few days' illness. The funeral took place at Lawnswood Cemetery, Leeds, on Thursday, Nov. 17. A wreath was sent by the District Manager and staff, and the funeral was attended by representatives from the office. Mr Blackburn joined the Telephone Service at Leeds in 1900, and was transferred to York on the re-organisation which took place in 1912. He was a man of a quiet disposition, and was greatly interested in cricket, and will be remembered by many no doubt by the interest he took in the staff cricket matches, in the Yorkshire districts some years ago. Mr. Blackburn was married as recently as June last.

It is with deep regret we have to report the death of Miss A. E. Sage, Telephonist, who passed away Nov. 20, 1921.

ANGLO-CONTINENTAL TELEGRAPH COMMUNICATIONS 1914-1921.

BY F. J. BINDER (Cable Room).

Continued from page 43.

London has now three new permanent lines, to Turin, Dresden and Berne respectively. The first-named provides an additional channel for the disposal of traffic for Italy, which country has expanded territorially by the inclusion of the Southern Tyrol and the busy Trieste area, and in addition Milan has been relieved of some of the Italian provincial traffic to enable her to handle traffic in transit for Yugo-Slavia and Fiume. Saxony and German Silesia are specially catered for by Dresden who, by virtue of proximity to the Bohemian frontier also, not infrequently, renders valuable assistance to Prague. Berne is a useful Swiss communication occupying a fine central position and offering (with Zurich) a good alternative route to Austria and Hungary in case of emergency.

Latterly Paris shares with Lyons the duty of disposing of telegrams for Alsace-Lorraine (now reconstituted as the three French departments of Haut Rhin, Bas Rhin and Moselle) and also generally assists with traffic for the new independent territory of the Sarre (or Saar).

The restoration of the communication with Magdeburg is improbable as this city has unfortunately suffered industrially and has now but little traffic.

The following list indicates the countries in the European telegraph system (including North Africa), for which telegrams, unless specifically otherwise ordered, are forwarded exclusively over the Government cables. The terminal and (where requisite) the normal re-transmitting stations are given, so that the number of transmissions required to reach any particular country is at once apparent. Where the distant terminal station indicated does not happen to be the capital of the country, one additional re-transmission normally suffices to reach it; as for example:—Zagreb—Belgrade or Zante—Athens.

Albania.
London—Rome—Valona.

Algeria.
London—Marseilles—Algiers (or Bona).

Andorra.
London—Marseilles—Perpignan—Bourg Madame—Andorre la Vieille.

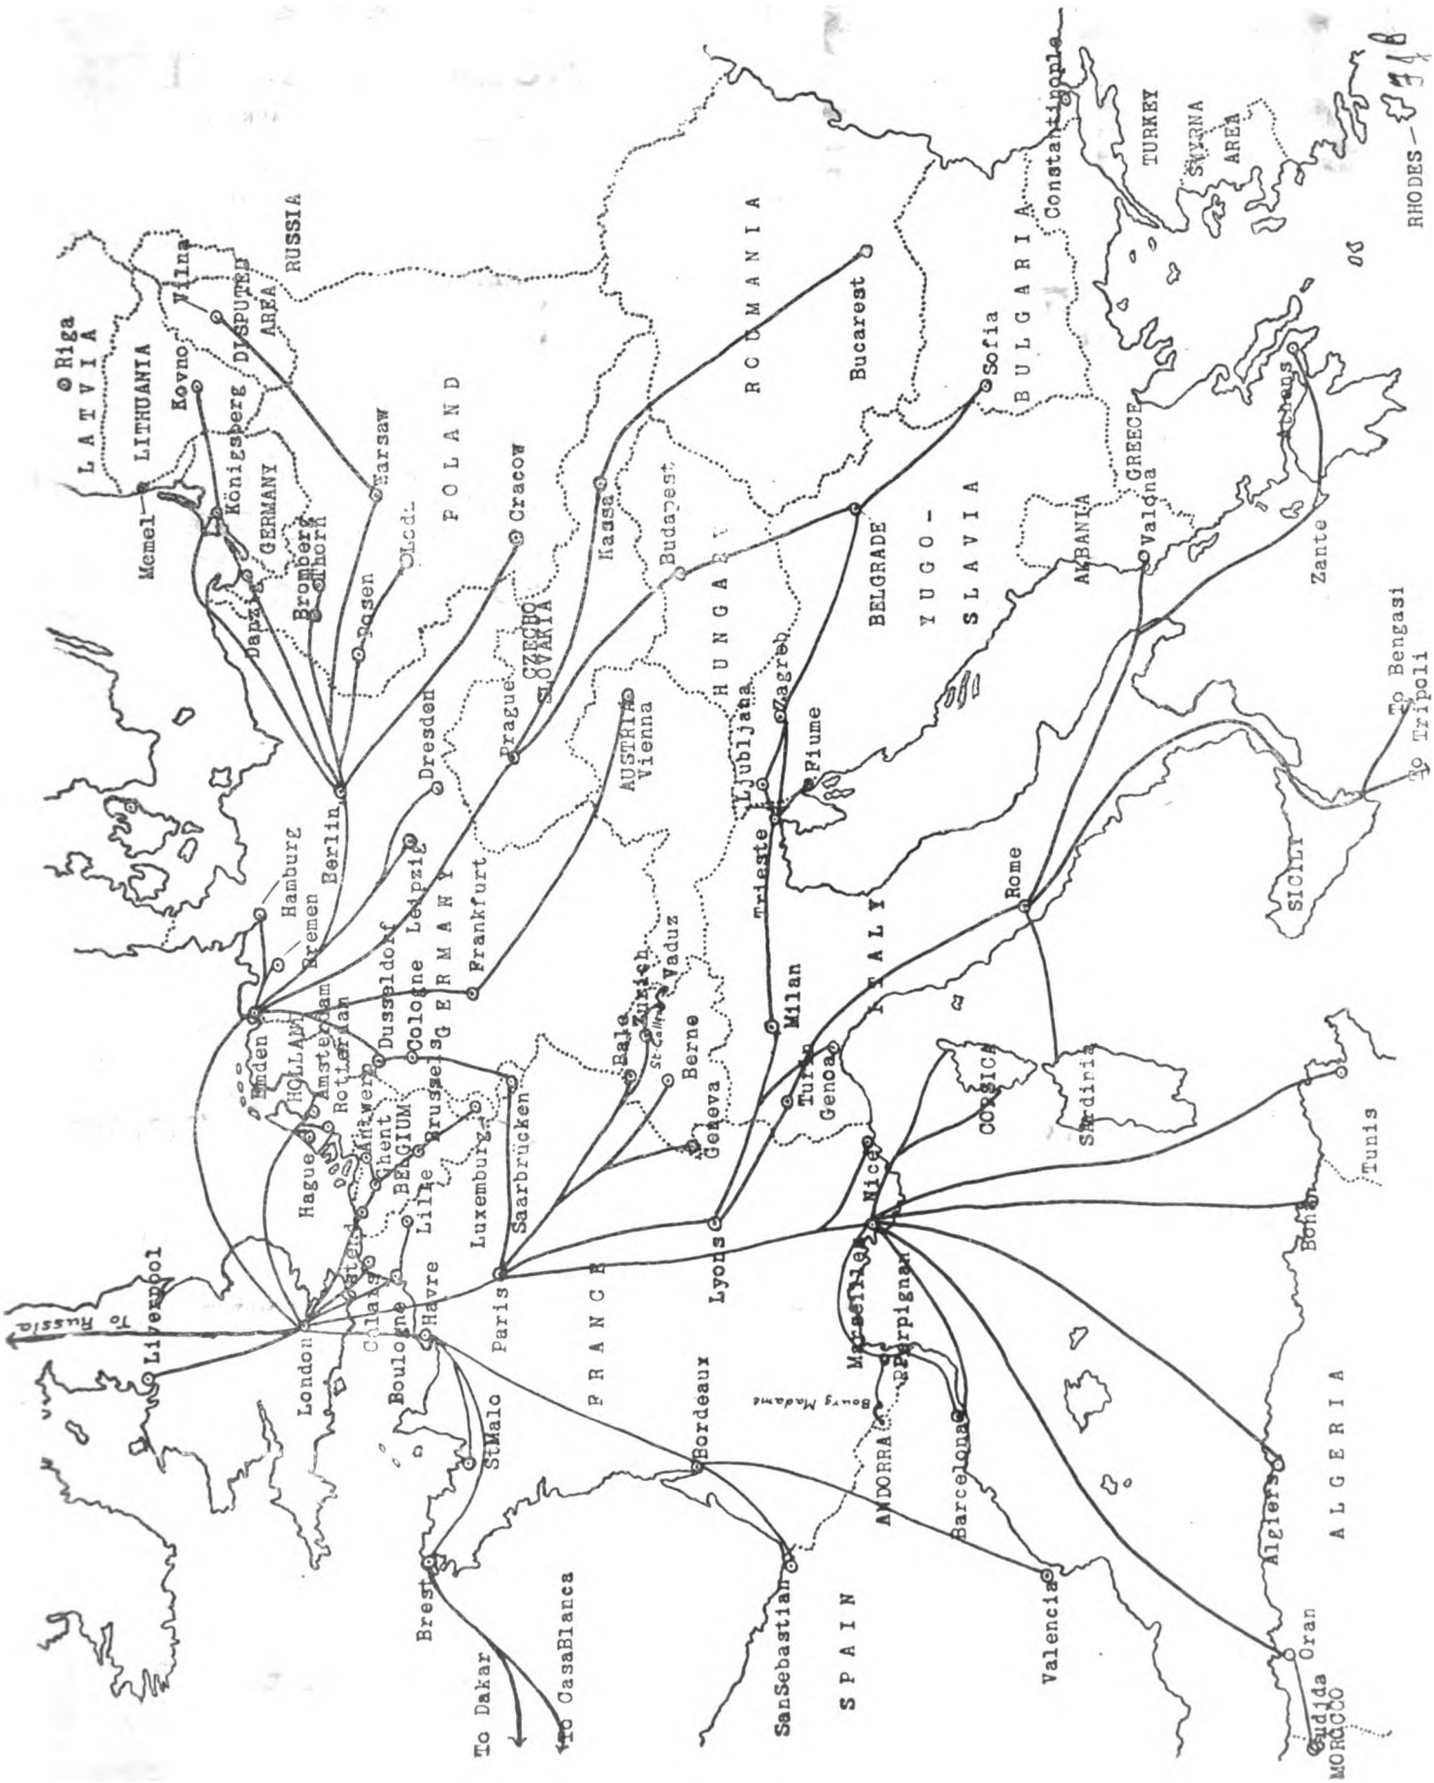
Austria.
London—Frankfurt-Main—Vienna.
(The direct line London—Vienna will probably soon be available.)

Belgium.
London—Antwerp.
" —Brussels.
" —Ghent.
" —Ostend.

Bulgaria.
London—Prague—Belgrade—Sofia.

Czecho-Slovakia.
London—Prague.

Danzig Free City Territory.
London—Berlin—Danzig.



**Esthonia.*
London—Berlin—Königsberg—Riga—Reval.

Fiume (Independent City).
London—Milan—Trieste—Fiume.

France.
London (or Liverpool)—Paris Central.
" —Paris Bourse.
" (or Liverpool)—Havre.
" —Bordeaux.
" —Boulogne-sur-mer.
" —Calais.
" —Lille.
" —Lyons.
" —Marseilles.
" —Nice } Seasonal.
" —St. Malo }

* The services to Esthonia and Latvia by means of the Government cable system were introduced during the preparation of this article. The references relating thereto have been duly included in the foregoing table, but it has not been found possible to revise the accompanying map accordingly, upon which a line should be shown from Königsberg (East Prussia) to Riga (Latvia) and thence northward in the direction of Reval (Esthonia) thus indicating the direct communications Königsberg-Riga and Riga-Reval as given in the table.

Digitized by Google

This map indicates the geographical position of the chief terminal and normal retransmitting offices engaged in the Anglo-Continental telegraph service. The approximate direction normally taken by the traffic to the various countries is shown, but no attempt has been made to indicate the number of lines available or the exact line-route followed.

Germany.
London—Berlin.
" —Bremen.
" —Cologne.
" —Dusseldorf.
" —Dresden.
" —Emden.
" —Frankfurt-Main.
" —Hamburg.
" —Leipzig.

Greece.
London—Rome—Zante.

Holland.
London—Amsterdam.
" —Amsterdam Bourse.
" —The Hague.
" —Rotterdam.

Hungary.
London—Prague—Budapest.

Italy.
London—Genoa.
" —Milan.
" —Rome.
" —Turin.

**Latvia.*
London—Berlin—Königsberg—Riga.

Kingdom of the Serbs Croats and Slovenes (Yugo-Slavia).
London—Milan—Trieste—Zagreb (or Ljubljana).

Libya.
London—Rome—(Sicily)—Tripoli (or Bengasi).

Liechtenstein.
London—Zurich—St. Gallen—Vaduz.

Lithuania.
London—Berlin—Konigsberg—Kovno.

Luxemburg.
London—Brussels—Luxemburg.

Morocco (French Zone).
London—Havre—Brest—Casa Blanca; or
London—Marseilles—Oran—Oudjda.

Poland.
London—Berlin—Warsaw (or alternatively Bromberg, Cracow, Posen, Lodz or Thorn).
(The direct communication London—Warsaw may soon be available.)

Rhodes.
London—Marseilles (thence *via* Eastern Company's cables).

Roumania.
London—Prague—Kassa—Bucarest.

Russia (Soviet).
London—Alexandrovsk (automatic re-transmission at Peterhead).

Sarre Territory.
London—Paris—Saarbruecken; or
London—Frankfurt-Main—Saarbruecken.

Spain (Eastern part).
London—Marseilles—Barcelona; or
London—Bordeaux—Valencia (or San Sebastian).

Switzerland.
London—Bale.
" —Berne.
" —Geneva.
" —Zurich.

Tunis.
London—Marseilles—Tunis.

West Africa (French Possessions).
London—Havre—Brest—Dakar.

Traffic for the European countries and islands not mentioned in the list, viz.:—Denmark, Egypt, Faroe Islands, Finland, Gibraltar, Iceland, Malta, Norway, Portugal, Spain (Central and Western), Spitzbergen, Sweden and Turkey is at present passed almost exclusively to one of the cable companies for disposal.

It will be noticed that the only Continental countries of importance, which are not normally reached in two transmissions from London are Bulgaria, Esthonia, the Kingdom of the Serbs Croats and Slovenes, Latvia, Lithuania and Roumania, and that the only capital of any importance, in addition to those of the six countries mentioned, which is not accessible in two transmissions is Athens.

In view of the distance to be traversed, it is perhaps too much to expect that the three transmissions necessary to reach Sofia and Athens, will be improved upon in the near future. Kovno (if it remains the capital of Lithuania), Riga and Reval will probably shortly enjoy direct communication with Berlin. The route followed to Bucarest, however, is capable of improvement, and the precarious condition of the lines eastward of the Slovakian frontier, renders urgently desirable the anticipated reversion to the use of the trunk line Budapest—Bucarest. With regard to Belgrade it is understood that the present route involving four transmissions is followed owing to the slightly lower transit rates offered, but facilities are available for this city to be reached in two transmissions (London—Prague—Belgrade), and that the Serbs are keenly alive to the advantages to be derived from the use of this route is evidenced by the fact that the bulk of their traffic reaches London from this direction.

THE BAUDOT—XXVIII.

By J. J. T.

It should be profitable here to note that the process of "taking the third" mentioned in our last article should not be confused with the adjustment for obtaining the *point of repere* on a working set, as already mentioned, which latter process is particularly useful in certain circumstances such as in the case of installations utilised on circuits fitted with repeaters, London-Rome, London-Milan, London-Marseilles, &c. These are cases in which although the *point of repere* is a local adjustment and is generally to be found at a distance of about $1\frac{1}{2}$ segments from the first small segment of ring one, the functioning of re-transmitting station nevertheless *does* vary slightly and it *does* happen that at times it becomes necessary to minutely increase the distance of the movable segment, and further, that this increase itself varies with adjustments made at the repeater office. This much may therefore be written in amplification of Article XXV, with reiterated stress on the injunction not to confuse this process with that already described for adjusting the small receiving segments (Ring 1) in order to obtain the peak of the current. Before leaving this most interesting subject of the *point of repere* for which there appears to be no translatable equivalent in our own tongue and to which the Germans have given the name of *merkpunkt* it should interest students to read the following and, so far as the writer knows, the best definition of the term yet given. Mr. H. H. Harrison, than whom there is probably no greater expert on Machine Telegraphy, says: "The *point of repere* is the line marking the coincidence of the end of the time of contact with the reversal from positive to negative of the correcting impulse."
